A

DICTIONARY

OF

ARTS, SCIENCES, AND GENERAL LITERATURE.

NINTH EDITION.

(AMERICAN REPRINT.)

WITH A COMPLETE INDEX.

VOLUME XXIII.

PHILADELPHIA:
J. M. STODDART CO., Limited.
1888.

~~AQ54
E19
1845
v.23~~

Entered, according to Act of Congress, in the year 1888, by the
EXECUTOR OF THE ESTATE OF ROGER SHERMAN, DECEASED,
In the Office of the Librarian of Congress, at Washington.

Sherman & Co.,
Printers, Phila'da.

Wm. Rutter & Co.,
Bookbinders, Phila'da.

ENCYCLOPÆDIA BRITANNICA.—VOL. XXIII.

PRINCIPAL CONTENTS.

TABLES, MATHEMATICAL. J. W. L. Glaisher.
TACITUS. Rev. W. J. Brodribb.
TAHITI. Baron Anatole von Hügel.
TALES. Andrew Lang.
TALLEYRAND. Thomas Shaw
TALLIS. W. S. Rockstro.
TALMUD. Dr. S. M. Schiller-Szinessy.
TAPE-WORMS. W. E. Hoyle.
TAR. J. Paton and Prof. W. Dittmar.
TARGUM. Dr. S. M. Schiller-Szinessy.
TASMANIA. James Bonwick.
TASSO. J. A. Symonds.
TASTE. Prof. J. G. M'Kendrick, M.D.
TAXATION. Prof. J. S. Nicholson.
TAYLOR, JEREMY. Rev. Marcus Dods, D.D.
TEA. James Paton.
TEAK. Sir Dietrich Brandis, K.C.I.E.
TECHNICAL EDUCATION. Sir Philip Magnus.
TELEGRAPH. Thomas Gray.
TELEPHONE. Thomas Gray.
TELESCOPE. David Gill, LL.D.
TEMPLARS. T. A. Archer.
TEMPLE. W. Robertson Smith, LL.D.
TENIERS. Henri Hymans.
TENNESSEE. Daniel F. Wright, M D.
TENNIS. Julian Marshall.
TERENCE. Prof. W. Y. Sellar, LL.D.
TERRA COTTA. Prof. J. H. Middleton.
TERTULLIAN. Prof. A. Harnack, D.D.
TEXAS. Robert T. Hill.
TEXTILES. Prof. J. H. Middleton.
THACKERAY. Walter H. Pollock.
THALES. Prof. G. J. Allman, LL.D., and Henry Jackson, Litt.D.
THEATRE. Prof. J. H. Middleton and James Williams.
THEBES. A. W. Verrall.
THEFT. James Williams.
THEISM. Rev. Prof. R. Flint, D.D.
THÉNARD. Prof. A. Crum Brown M.D.
THEOCRITUS. Andrew Lang.
THEODORA. Prof. James Bryce, D.C.L., M.P.
THEODORIC. T. Hodgkin, D.C.L.
THEOLOGY. Prof. R. Flint.
THEOSOPHY. Prof. Andrew Seth.
THERMODYNAMICS. Prof. P. G. Tait.
THERMOMETER. H. R. Mill, D. Sc.
THESSALONIANS. Prof. E. Schürer.
THESSALY. Rev. H. F. Tozer.
THIBAUT. John Macdonell.
THIERS. George Saintsbury.
THIRLWALL. R. Garnett, LL.D.
THOMSON, JAMES. Prof. Wm. Minto.
THOREAU. William Sharp.
THOUSAND AND ONE NIGHTS. Prof. M. J. de Goeje.
THRACE. Rev. H. F. Tozer.
THROAT DISEASES. J. O. Affleck, M.D.
THUCYDIDES. Prof. R. C. Jebb, LL.D.
THUGS. Reinhold Rost, LL.D., C.I.E.
THULE. Sir E. H. Bunbury, Bart.
THURLOW. A. Wood Renton.
TIBET. General J. T. Walker, R.E., C.B., and Prof. A. Terrien de Lacouperie.
TIBULLUS. Prof. J. P. Postgate.
TIDES. Prof. G. H. Darwin.
TIECK. Richard Garnett, LL.D.
TIGER. Prof. W. H. Flower.
TILES. Prof. J. H. Middleton.
TIME. J. L. E. Dreyer, Ph.D.
TIMUR. Maj.-Gen. Sir Frederick J. Goldsmid, K.C.S.I., C.B.
TINAMOU. Prof. Alfred Newton.
TITIAN. W. M. Rossetti.
TOBACCO. James Paton and Prof. W. Dittmar.
TONG-KING. Prof. R. K. Douglas.
TONNAGE. W. Moore.
TOOKE. W. P. COURTNEY.
TORONTO. Daniel Wilson, LL.D.
TORPEDO. Comm. E. J. P. Gallwey.
TORT. Prof. F. Pollock, LL.D.
TORTOISE. Albert Günther, M.D.
TORTURE. James Williams.
TOTEMISM. J. G. Frazer.
TOUCAN. Prof. A. Newton.
TOUCH. Prof. J. G. M'Kendrick.
TOULOUSE. Gaston Meissas and T. A. Archer.
TOURNEUR. A. C. Swinburne.
TRACTION. Prof. J. A. Ewing.
TRADE UNIONS. Fred. Drummond.
TRAJAN. J. S. Reid. Litt.D.
TRAMWAY. Thomas Codrington.
TRANSIT CIRCLE. J. L. E. Dreyer.
TRANSVAAL. Prof. A. H. Keane.
TREASON. James Williams.
TREATIES. Prof. T. E. Holland. D.C.L.
TREMATODA. W. E. Hoyle.
TRENT, COUNCIL OF. Rev. R. F. Littledale, D.C.L.
TRIBUNE. J. S. Reid, Litt.D.
TRICYCLE. C. V. Boys.
TRIGONOMETRY. E. W. Hobson.
TRIPOLI. A. M. Broadley.
TROAD. Prof. R. C. Jebb.
TRUMPET. Victor Mahillon.
TRUST. James Williams.
TUNICATA. Prof. W. A. Herdman.
TUNNELLING. Benjamin Baker, C.E.
TURGOT. J. K. Ingram, LL.D.
TURKESTAN. P. A. Kropotkine.
TURKEY—
History and Literature. E. J. W. Gibb and C. A. Fyffe.
Geography and Statistics. Prof. A. H. Keane.
TURKS. Prof. M. Th. Houtsma.

T.

T is the twentieth symbol in our alphabet. It has varied but little in form since the earliest days when it appeared in Greece and Italy, though some of the Italic alphabets exhibit variants: *e.g.*, in Umbrian and Etruscan inscriptions we find the horizontal stroke sometimes on one side only, and slanting; sometimes the form is nearly that of our ordinary small *t* without the ornamental turn at the bottom. In value it has been in all languages a surd or voiceless dental, corresponding to *d*, which is voiced. But the term "dental" includes some varieties of position, of which the most definite are—(1) where the point of the tongue touches the teeth (true "dental"), as in French; (2) where the tongue touches the gum behind the teeth, and not the teeth at all, as in English; (3) where the point of the tongue is slightly bent back against the palate, producing the sound much heard in south India (often called "cerebral"). T when followed by *i* or *y* is liable to pass into the *s*-sound; this happened in the local dialects of Italy before the Christian era; at Rome the transition was later. This changed sound passed on into the Romance languages, *e.g.*, in French "nation," pronounced "nasion," whence in England it was sounded first as "nasiun" and now as "nashun." Similarly in English *t* followed by *u* undergoes a change of sound; this is due, however, to the old sound of *ū*, viz., long French *u*, or Old English *y*. This long *yy* developed into the *iu* sound heard in "use," "cure," etc.; then the new *i* affected the preceding *t*, and the result is *tsh*, as in "nature" (natshure); similarly *d* in "verdure" is sounded as *dzh* (verdzhure).

English employs the digraph *th* to denote two sounds, differing as voiceless and voiced sounds—the initial sounds of "thin" and "then" respectively. It would be a great convenience if *dh* could be used for the voiced sound, so that "then" should be written "dhen." But it would be even better if the single symbols could be employed to denote these single sounds, as was to some extent the case in the earlier days of our language: in Anglo-Saxon we have the two symbols ð and þ. The first is only a *d* crossed; the second was a rune and was called "thorn." These, however, were not consistently employed one for the voiceless and one for the voiced sound; also *th* is actually found in the oldest texts, and later on it occurs together with ð and þ. It is probable that the voiceless sound was originally the only one in Teutonic. It was eventually differentiated into two sounds; but, as is usually the case, writing remained more archaic than speech. In modern English and Icelandic, and probably in the parent Teutonic also, initial *th* is voiceless, except in English in a small number of pronouns and particles in common use, as "thou," "this," "that," "then," "than," "though," "thus"; and it is regularly voiceless when final. The nature of the two sounds is this: the tongue is pressed against the back of the teeth (sometimes, especially when used by foreigners, against the bottom of the upper teeth) and either the breath for *th* or the voice for *dh* is forced through the interstices of the teeth. This pair of sounds is found in modern Greek, where *th* appears as θ and *dh* as δ. In Spanish and in Danish under certain circumstances the sound denoted by *d* is *dh*.

TABARÍ AND EARLY ARAB HISTORIANS. Arabian historians differ from all others in the unique form of their compositions. Each event is related in the words of eye-witnesses or contemporaries transmitted to the final narrator through a chain of intermediate reporters (*ráwís*), each of whom passed on the original report to his successor. Often the same account is given in two or more slightly divergent forms, which have come down through different chains of reporters. Often, too, one event or one important detail is told in several ways on the basis of several contemporary statements transmitted to the final narrator through distinct lines of tradition. The writer therefore exercises no independent criticism except as regards the choice of authorities; for he rejects accounts of which the first author or one of the intermediate links seems to him unworthy of credit, and sometimes he states which of several accounts seems to him the best. Modern judgment does not always confirm this choice; some authorities much esteemed by Moslems are by European scholars deemed untrustworthy, and *vice versa*. Fortunately the various historians did not always give preference to the same account of a transaction, and so one supplies what another omits.

A second type of Arabian historiography is that in which an author combines the different traditions about one occurrence into one continuous narrative, but prefixes a statement as to the lines of authorities used and states which of them he mainly follows. In this case the writer recurs to the first method, already described, only when the different traditions are greatly at variance with one another. In yet a third type of history the old method is entirely forsaken and we have a continuous narrative only occasionally interrupted by citation of the authority for some particular point. But the principle still is that what has been well said once need not be told again in other words. The writer therefore keeps as close as he can to the letter of his sources, so that quite a late writer often reproduces the very words of the first narrator.

From very early times the Arabs had great delight in verses and tales, and the development of their language was certainly much influenced by this fact. In ancient times story-tellers and singers found their subjects in the doughty deeds of the tribe on its forays, in the merits of horse or camel, in hunting adventures and love complaints, and sometimes in contests with foreign powers and in the impression produced by the wealth and might of the sovereigns of Persia and Constantinople. The appearance of the Prophet with the great changes that ensued, the conquests that made the Arabs—till then a despised race—lords of half the civilized world, supplied a vast store of new matter for relations which men were never weary of hearing and recounting. They wished to know everything about the apostle of God, whose influence on his own time was so enormous, who had accomplished all that seemed impossible and had inspired the Arabs with a courage and confidence that made them stronger than the legions of Byzantium and Ctesiphon. Every one who had known or seen him was questioned and was eager to answer. Moreover, the word of God in the Koran left many practical points undecided, and therefore it was of the highest importance to know exactly how the Prophet had spoken and acted in various circumstances. Where could this be better learned than at Medina, where he had lived so long and where the majority of his companions continued to live? So at Medina a school was gradually formed, where the chief part of the traditions about Mohammed and his first successors took a form more or less fixed. Soon divers fathers of Islam began to assist memory by making notes, and their disciples sought to take written jottings of what they had heard from them, which they could carry with them when they returned to their homes. Thus by the close of the 1st century many *dictata* were already in circulation. For example, Ḥasan of Baṣra (d. 110 A.H.; 728 A.D.) had a great mass of such notes, and he was accused of sometimes passing off as oral tradition things he had really drawn from books; for oral tradition was still the one recognized authority, and it is related of more than one old scholar, and even of Ḥasan of Baṣra himself, that he directed his books to be burned at his death. The books were mere helps, and what they knew these scholars had handed on by word of mouth. Long after this date, when all scholars drew mainly from books, the old forms were still kept up. Ṭabarí, for example, when he cites a book expresses himself as if he had heard what he quotes from the master with whom he read the passage or from whose copy he transcribed it. He even expresses himself in this wise: "'Omar b. Shabba has related to me in his book on the history of Baṣra."

Historians before Ṭabarí.

Naturally, then, no independent book of the 1st century from the Flight has come down to us. But in the 2d century real books began to be composed. The materials were supplied in the first place by oral tradition, in the second by the *dictata* of older scholars, and finally by various kinds of documents, such as treaties, letters, collections of poetry, and genealogical lists. Genealogical studies had become necessary through 'Omar's system of assigning state pensions to certain classes of persons according to their kinship with the Prophet, or their deserts during his lifetime. This subject received much attention even in the 1st century, but books about it were first written in the 2d, the most famous being those of Ibn al-Kalbí (d. 146 A.H.), of his son Hishám[1] (d. 204), and of Al-Sharḳí ibn al-Ḳoṭámí. Genealogy, which often called for elucidations, led on to history. Beládhorí's excellent *Ansáb al-Ashráf* (Genealogies of the Nobles) is a history of the Arabs on a genealogical plan.

The oldest extant history is the biography of the Prophet by Ibn Isḥáḳ[2] (d. 150). This work is generally trustworthy. Mohammed's life before he appeared as a prophet and the story of his ancestors are indeed mixed with many fables illustrated by spurious verses. But in Ibn Isḥáḳ's day these fables were generally accepted as history—for many of them had been first related by contemporaries of Mohammed—and no one certainly thought it blameworthy to put pious verses in the mouth of the Prophet's forefathers, though, according to the *Fihrist* (p. 92), Ibn Isḥáḳ was duped by others with regard to the poems he quotes.

The *Life* of the Prophet by Ibn 'Oḳba (d. 141), based on the statements of two very trustworthy men, 'Orwa ibn az-Zobair (d. 94) and Az-Zohrí (d. 124), seems to be quite lost, Sprenger having vainly made every effort to find a copy. It was still much read in Syria in the 14th century. But we fortunately possess the *Book of the Campaigns* of the Prophet by Al-Wáḳidí (d. 207) and the important *Book of Classes* of his disciple Ibn Sa'd.[3] Wáḳidí had much more copious materials than Ibn Isḥáḳ, but gives way much more to a popular and sometimes romancing style of treatment. Nevertheless he sometimes helps us to recognize in Ibn Isḥáḳ's narrative modifications of the genuine tradition made for a purpose, and the additional details he supplies set various events before us in a clearer light. Apart from this his chief merits lie in his studies on the subject of the traditional authorities, the results of which are given by Ibn Sa'd, and in his chronology, which is often excellent. A special study of the traditions about the conquest of Syria made by De Goeje in 1864 led to the conclusion that Wáḳidí's chronology is sound as regards the main events, and that later historians have gone astray by forsaking his guidance. This result has been confirmed by certain contemporary notices found by Nöldeke in 1874 in a Syriac MS. of the British Museum. And that Ibn Isḥáḳ agrees with Wáḳidí in certain main dates is important evidence for the trustworthiness of the former also. For the chronology before the year 10 of the Flight Wáḳidí did his best, but here, the material being defective, many of his conclusions are precarious. Yet, though we have good ground for doubts, we are seldom able to construct a better chronology. Wáḳidí had already a great library at his disposal. He is said to have had 600 chests of books, chiefly *dictata* written by or for himself, but in part real books by Abú Mikhnaf (d. 130), Ibn Isḥáḳ (whom he uses but does not name), 'Awána (d. 147), and other authors. Abú Mikhnaf left a great number of monographs on the chief events from the death of the Prophet to the caliphate of Walíd II. These were much used by later writers, and we have many extracts from them, but none of the works themselves, except a sort of romance based on his account of the death of Ḥosain, of which Wüstenfeld has given a translation. With regard to the history of 'Iráḳ in particular he was deemed to have the best lights, and for this subject he is Ṭabarí's chief source, just as Madáiní, a younger contemporary of Wáḳidí, is followed by preference in all that relates to Khorásán. Madáiní's *History of*

[1] Of Hishám b. al-Kalbí's book there are copies in the British Museum and in the Escorial.

[2] Ibn Isḥáḳ's original work seems to be still extant in the Köprülü library at Constantinople; the edition of it by Ibn Hishám has been edited by Wüstenfeld (Göttingen, 1858-60) and translated into German by Weil (Stuttgart, 1864).

[3] Wáḳidí has been edited from an imperfect MS. by Kremer (Calcutta, 1856). A condensed translation by Wellhausen appeared in 1882. The great book of Ibn Sa'd is unpublished, but there are some useful papers on it by Loth.

the Caliphs is the best if not the oldest published before Ṭabarí; but this book has quite disappeared and is known only by the excerpts given by later writers, particularly Beládhorí and Ṭabarí. From these we judge that he had great narrative power with much clear and exact learning, and must be placed high as a critical historian. His plan was to record the various traditions about an event, choosing them with critical skill; sometimes, however, he fused the several traditions into a continuous narrative. A just estimate of the relative value of the historians can only be reached by careful comparison in detail. This has been essayed by Brünnow in his study on the Khárijites (Leyden, 1884), in which the narrative of Mobarrad in the Kámil is compared with the excerpts of Madáiní given by Beládhorí and those of Abú Mikhnaf given by Ṭabarí. The conclusion reached is that Abú Mikhnaf and Madáiní are both well informed and impartial.

Among the contemporaries of Wáḳidí and Madáiní were Ibn Khidásh (d. 223), the historian of the family Mohallab, whose work was one of Mobarrad's sources for the *History of the Khárijites;* Haitham ibn 'Adí (d. 207), whose works, though now lost, are often cited; and Saif ibn 'Omar at-Tamímí, whose book on the revolt of the tribes under Abú-bekr and on the Mohammedan conquests was much used by Ṭabarí. Saif, however, seems to have been little esteemed; Beládhorí very seldom cites him, and nothing can be found in Arabic literature about his life and those of his authorities. He is barely mentioned in the *Fihrist*, the writer plainly having nothing to tell of him, and blundering in the one thing he does say by representing his disciple Sho'aib as his master. Hájji Khalífa knows nothing but his name. His narratives are detailed and often tinged with romance, and he is certainly much inferior to Wáḳidí in accuracy. Besides these are to be mentioned Abú 'Obaida (d. 209), who was celebrated as a philologist and wrote several historical monographs that are often cited, and Azraḳí, whose excellent *History of Mecca* was published after his death by his grandson (d. 244). With these writers we pass into the 3d century of Islam. But we have still an important point to notice in the 2d century; for in it learned Persians began to take part in the creation of Arabic historical literature. Ibn Moḳaffa' translated the great *Book of Persian Kings*, and others followed his example. Ṭabarí and his contemporaries, senior and junior, such as Ibn Ḳotaiba, Ya'ḳúbí, Dínawarí, preserve to us a good part of the information about Persian history made known through such translations.[1] But even more important than the knowledge conveyed by these works was their influence on literary style and composition. Half a century later began versions from the Greek either direct or through the Syriac. The pieces translated were mostly philosophical; but the Arabs also learned something, however superficially, of ancient history.

The 3d century was far more productive than the 2d. Abú 'Obaida was presently succeeded by Ibn al-A'rábí (d. 231), who in like manner was chiefly famous as a philologist, and who wrote about ancient poems and battles. Much that he wrote is quoted in Tabrízí's commentary on the *Ḥamása*, which is still richer in extracts from the historical elucidations of early poems given by Ar-Riyáshí (d. 257). Of special fame as a genealogist was Ibn Ḥabíb (d. 245), of whom we have a booklet on Arabian tribal names published by Wüstenfeld (1850). Azraḳí again was followed by Fákihí, who wrote a *History of Mecca* in 272,[2] and 'Omar b. Shabba (d. 262), who composed an excellent history of Baṣra, known to us only by excerpts. Of the works of Zobair b. Bakkár (d. 256), one of Ṭabarí's teachers, a learned historian and genealogist much consulted by later writers, there is a fragment in the Köprülü library at Constantinople, and another in Göttingen, part of which has been made known by Wüstenfeld (*Die Familie Al-Zobair*, Göttingen, 1878). Ya'ḳúbí or Ibn Wádiḥ wrote a short general history of much value, published by Houtsma (Leyden, 1883). About India he knows more than his predecessors and more than his successors down to Bèrúní. Ibn Khordádbeh's historical works are lost. Ibn 'Abdalḥakam (d. 257) wrote of the conquest of Egypt and the West. Extracts from this book are given by De Slane in his *Histoire des Berbères*, and others by Karle and Jones, from which we gather that it was a medley of true tradition and romance, and must be reckoned, with the book of his slightly senior contemporary, the Spaniard Ibn Ḥabíb, to the class of historical romances (see below, p. 9). A high place must be assigned to the historian Ibn Ḳotaiba (d. 276), who, as Rosen has well shown, wrote a series of books with a view to raising the scholarship of the large class of *kátibs* or official scribes. To this series belong his very useful *Handbook of History* (ed. Wüstenfeld, Göttingen, 1850) and his '*Oyún al-Akhbár*, though the latter book according to the arrangement falls rather under the class of *litteræ humaniores*. Much more eminent is Beládhorí (d. 279), whose book on the Arab conquest (ed. De Goeje, Leyden, 1865–66) merits the special praise given to it by Mas'údí. Of his great *Ansáb al-Ashráf* a large part exists at Paris in the valuable collection of M. Schefer and another part was published by Ahlwardt in 1884. A contemporary, Ibn abí Ṭáhir Taifúr (d. 280), wrote on the 'Abbásid caliphs and was drawn on by Ṭabarí. The sixth part of his work is in the British Museum. Of the universal history of Dínawarí (d. 282), entitled *The Long Narratives*, an edition by Girgas is now (1887) in the press.

Ṭabarí.

All these histories are more or less thrown into the shade by the great work of Ṭabarí, whose fame has never faded from his own day to ours, and who well deserves to have this article on early Arabic histories placed under his name. Abú Ja'far Mohammed b. Jarír at-Ṭabarí (so his full name runs) is described as a tall lean figure, with large eyes, brown complexion, and hair which remained black till his death. His learning was astounding and few could speak so well. Born 224 A.H. (838–9 A.D.) at Amol in Ṭabaristán, he came to Baghdad as a young man and heard there the most famous teachers of the age. He travelled through Syria and Egypt (where he was in 263), and finally settled down in Baghdad, where he remained till his death in 310 (922 A.D.), always active and surrounded by pupils. He is said to have written forty pages daily for forty years. This no doubt is an exaggeration, but certainly he must have been a man of most persistent industry. His two chief works are a great *Commentary on the Koran* and his *Annals*. There is an anecdote to the effect that each originally filled 30,000 leaves, but that his pupils found them too extensive to be written to his dictation, and that he then resolved to condense them to a tenth of their original size, exclaiming, "God help us! Ambition is extinct." One cannot say how far this story is true, but it is probable enough that his materials, at least for the *Annals*, were many times greater than the book itself. Where the same topic comes up in the *Annals* and in the *Commentary* we often find different traditions quoted, or the same tradition derived through different channels, and this shows the copious variety of his sources. Various parts of the *Annals* give the impression of being condensed. The *Commentary* was published before the *Annals*, and is better composed. It is the head corner-stone of Koran exegesis, as the *Annals* are of historiography. It came into general use mainly through the abridgment of Baghawí in the beginning of the 6th century of the Flight, being itself too large to be much read. The great book exists complete in the viceregal library at Cairo, and ought to be published at once.[1]

---

[1] For details see the introduction to Nöldeke's excellent translation of Ṭabarí's *History of the Persians and Arabs in the Sasanian Period*, Leyden, 1879.

[2] Published in excerpt by Wüstenfeld along with Azraḳí, Leipsic, 1857–59.

The *Annals* are a general history from the creation to 302 A.H., and are in the course of publication at Leyden. They will fill some 7000 to 7500 pages, one and a half printed pages corresponding roughly to one leaf of Ṭabarí's original MS. Ṭabarí added a supplement about his authorities, an abridgment of which is to follow the Leyden edition. It contains biographical notices of traditionalists, contemporaries of Mohammed, and their successors to the second half of the 2d century.[2] Other works by Ṭabarí will be spoken of in detail in the preface to the Leyden edition.

The success of the *Annals* and *Commentary* was due above all to the author's personality. The respect paid to him by his contemporaries appears in various anecdotes preserved in his biography. His pupils had an unbounded admiration for his extraordinary knowledge, and what he said seemed to them the best that could be said. In truth, both his great works were the best of their kind, especially the *Commentary*, which, in the judgment of all impartial critics, has not been equalled, before or since, in completeness, learning, and independent judgment. A contemporary says that "it would be worth a journey to China to procure the book." So general was this view that the opinion of Ṭabarí was quoted as a legal authority.

The inferiority of the *Annals* as a literary composition may be due partly to the author's years, partly to the inequality of his sources, sometimes superabundant, sometimes defective, partly perhaps to the somewhat hasty condensation of his original draft. Nevertheless the value of the book is very great: the author's selection of traditions is usually happy, and the episodes of most importance are treated with most fulness of detail, so that it deserves the high reputation it has enjoyed from the first. This reputation rose steadily; there were twenty copies (one of them written by Ṭabarí's own hand) in the library of the Fátimite caliph ‘Azíz (latter half of the 4th century), whereas, when Saladin became lord of Egypt, the princely library contained 1200 copies (Maḳrízí, i. 408 *sq.*). Only princes and rich men could own a book which in the time of ‘Azíz cost one hundred dinars. We know that it had a place in most great libraries in other countries, for we find that it was used in all lands. Thus the fact that no complete copy can now be found anywhere, and that the Leyden edition rests on odd volumes lying in various places, gives a striking image of what the East has suffered from barbarism.

The *Annals* soon came to be dealt with in various ways. They were published in shorter form with the omission of the names of authorities and of most of the poems cited; some passages quoted by later writers are not found even in the Leyden edition. On the other hand, some interpolations took place, one in the author's lifetime and perhaps by his own hand. Then many supplements were written, *e.g.*, by Ferghání (not extant) and by Hamadhání (partly preserved in Paris). ‘Aríb of Cordova made an abridgment, adding the history of the West and continuing the story to about 365.[3] Ibn Mashkawaih wrote a history from the creation to 369 A.H., with the purpose of drawing the lessons of the story, following Ṭabarí closely, as far as his book is known, and seldom recurring to other sources before the reign of Moḳṭadir; what follows is his own composition, and shows him to be a writer of talent.[4] In 352 an abridgment of the *Annals* was translated into Persian by Bal‘amí, who, however, interwove many fables.[5] Ibn al-Athír (d. 630) abridged the whole work, usually with judgment, but sometimes too hastily. Though he sometimes glided lightly over difficulties, his work is of service in fixing the text of Ṭabarí. He also furnished a continuation to the year 620. Later writers took Ṭabarí as their main authority, but fortunately sometimes consulted other sources, and so add to our knowledge,—especially Ibn al-Jauzí (d. 597), who adds many important details. These later historians had valuable help from the biographies of famous men and special histories of countries and cities, dynasties and princes, on which much labor was spent from the 4th century onwards.

Historians after Ṭabarí.

The chief historians after Ṭabarí may be briefly mentioned in chronological order. Rází (d. 325) wrote a *History of Spain*; Eutychius (d. 328) wrote *Annals* (published by Pocock, Oxford, 1656), which are very important because he gives the Christian tradition; Ibn ‘Abd Rabbihi (d. 328) has very valuable historical passages in his famous miscellany called *Al-‘Iḳd al-Faríd* (3 vols., Cairo, 1293 A.H.); Ṣúlí (d. 335) wrote on the ‘Abbásid caliphs, their viziers and court poets; Mas‘údí (see MAS‘ÚDY) composed various historical and geographical works (d. 345). Of Ṭabarí's contemporary Ḥamza Ispahání, we have the *Annals* (published by Gottwaldt, St. Petersburg, 1844); Abu 'l-Faraj al-Ispahání (d. 356) in his *Book of Songs* (*Kitáb al-Aghání*, 20 vols., Cairo, 1285) gave the lives of poets whose songs were sung; Ibn al-Ḳútíya (d. 367) wrote a *History of Spain*; Ibn Zúlák (d. 387) a *History of Egypt*; ‘Otbi wrote the *History of Maḥmúd of Ghazna* (d. 421), at whose court he lived (printed on the margin of the Egyptian edition of Ibn al-Athír); Tha‘labí (d. 427) wrote a well-known *History of the Old Prophets*; Abú No‘aim al-Ispahání (d. 430) wrote a *History of Ispahan*, chiefly of the scholars of that city; Tha‘álibí (d. 429 or 430) wrote, *inter alia*, a well-known *History of the Poets of his Time*, now (1887) in course of publication at Damascus. Bèrúní (d. 440) takes a high place among historians by his *Chronology of Ancient Nations* (ed. Sachau, Leipsic, 1878; Eng. trans., London, 1879) and his contributions to the history of India and Khwárizm; Ḳoḍá‘í (d. 454) wrote a *Description of Egypt* and also various historical pieces, of which some are extant; Ibn Ṣá‘id of Cordova (d. 462) wrote a *View of the History of the Various Nations*. Baghdad and its learned men found an excellent historian in Al-Khatíb al-Baghdádí (d. 463), and Spain in Ibn Hayán (d. 469) and half a century later in Ibn Khaḳán (d. 529) and Ibn Bassám (d. 542). Sam‘ání (d. 562) wrote an excellent book on genealogies; Ibn ‘Asákir (d. 571) a *History of Damascus and her Scholars*, which is of great value, and exists in whole or in part in several libraries. The *Biographical Dictionary* of the Spaniard Ibn Pascual (d. 578) and that of Ḍabbí, a somewhat junior contemporary, are edited in Codera's *Bibliotheca Arab. Hisp.* (1883-1885); Saladin found his historian in the famous ‘Imád addín (d. 597). Ibn al-Jauzí, who died in the same year, has been already mentioned. Abdalwáḥid's *History of the Almohades*, written in 621, was published by Dozy (2d ed., 1881). The geographer Yáḳút (d. 626) wrote also some historical works, now lost. Abdallaṭíf (d. 629) is known by his writings about Egypt (trans. De Sacy, 1810); Ibn al-Athír (d. 630) wrote, in addition to the *Chronicle* already mentioned, a *Biographical Dictionary of Contemporaries of the Prophet*. Ḳifṭí (d. 646) is especially known by his *History of Arabic Philologists*. Sibt ibn al-Jauzí (d. 654), grandson of the Ibn al-Jauzi already mentioned, wrote a great *Chronicle*, of which much the larger part still exists. Codera has edited (Madrid, 1886) Ibn al-‘Abbár's (d. 658) *Biographical Lexicon*, already known by Dozy's excerpts from it. Ibn al-‘Adím (d. 660) is famed for his *History of Aleppo*, and Abú Sháma (d. 665) wrote a well-known *History of Saladin and Nureddín*, taking a great deal from ‘Imád addín. A. Müller has recently published (1885) Ibn abí Osaibia's (d. 668) *History of Physicians*. The *History* of Ibn al-‘Amíd (d. 675), better known as ELMACIN (*q.v.*), was printed by Erpenius in 1625. Ibn Sa‘íd al-Maghribí (d. 673 or 685) is famous for his histories, but still more for his geographical writings. The noted theologian NAWAWÍ (*q.v.*; d. 676) wrote a *Biographical Dictionary of the Worthies of the First Ages of Islam*. Preeminent as a biographer is Ibn Khallikán (d. 681), whose much-used work was partly edited by De Slane and completely by Wüstenfeld (1835-40), and translated into English by the former scholar (4 vols., 1843-71).

---

[1] See the excellent article by Loth in *Z.D.M.G.*, xxxv. 588 *sq.*

[2] The MS. containing this abridgment is described by Loth in *Z.D.M.G.*, xxxii. 581 *sq.* It is now in the British Museum.

[3] Of this work the Gotha library has a portion containing 290-320 A.H., of which the part about the West has been printed by Dozy in the *Bayán*, and the rest is to be published at Leyden.

[4] A fragment (198-251 A.H.) is printed in De Goeje, *Fragm. Hist. Ar.*, vol. ii., Leyden, 1871. Schefer possesses an excellent MS. of the years 249-315; Oxford has another fragment, 345-360 A.H.; the second part is in the Escorial.

[5] The first part was rendered into French by Dubeux in 1836. We have now an excellent French translation by Zotenberg, 1874.

Abu ’l-Faraj, better known as Bar-Hebræus (d. 685), wrote besides his Syriac *Chronicle* an Arabic *History of Dynasties* (ed. Pocock, Oxford, 1663). Ibn ‘Adhárí’s *History of Africa and Spain* has been published by Dozy (2 vols., Leyden, 1848–51), and the *Ḳartás* of Ibn abí Zar‘ by Tornberg (1843). One of the best known of Arab writers is Abulfeda (d. 732), whose *Annales Moslemici* were published with a Latin version by Reiske (Copenhagen, 5 vols. 4to, 1789-91). The *History of the Time before Mohammed* has been published by Fleischer (1831). Not less famous is the great *Encyclopædia* of his contemporary Nowairí (d. 732), but only some extracts are as yet in print. Ibn Sayyid an-Nás (d. 734) wrote a full biography of the Prophet; Mizzí (d. 742) an extensive work on the men from whom traditions have been derived. We still possess, nearly complete, the great *Chronicle* of Dhahabí (d. 748), a very learned biographer and historian. A complete edition of the geographical and historical *Masálik al-Abṣár* of Ibn Faḍlalláh (d. 749) is much to be desired. It is known at present by extracts given by Quatremère and Amari. Ibn al-Wardí (d. 749 or 750), best known by his *Cosmography*, wrote a *Chronicle* which has been printed in Egypt. Safadí (d. 764) got a great name as a biographer. Yáfi‘í (d. 768) wrote a *Chronicle of Islam* and *Lives of Saints*. Sobkí (d. 771) published *Lives of the Theologians of the Sháfi‘ite School.* Of Ibn Kathír’s *History* the greatest part is extant. For the history of Spain and the Maghrib the writings of Ibn al-Khatíb (d. 776) are of acknowledged value. Another history, of which we possess the greater part, is the large work of Ibn al-Forát (d. 807). Far superior to all these, however, is the famous Ibn Khaldún (d. 808), who proves himself a great thinker in the *Prolegomena to his Universal History*. Of the *Prolegomena* there are an edition by Quatremère (1858) and a French version by De Slane (1863). The latter scholar also published text and version of the *History of the Berbers*, and there is a poor Egyptian edition of the whole work. Of the historical works of the famous lexicographer Fírúzabádí (d. 817) only a *Life of the Prophet* remains. MAḲRIZI (d. 845) is spoken of in a separate article; Ibn Hajar (d. 852) is best known by his *Biographical Dictionary of Contemporaries of the Prophet*, now in course of publication in the *Bibliotheca Indica*. Ibn ‘Arabsháh (d. 854) is known by his *History of Tímúr* (Leeuwarden, 1767). ‘Ainí (d. 855) wrote a *General History*, still extant. Abu ’l-Mahásin (d. 874) wrote at length on the history of Egypt; the first two parts have been published by Juynboll. Flügel has published Ibn Kotlubogha’s *Biographies of the Ḥanafite Jurists*. Ibn Shiḥna (d. 890) wrote a *History of Aleppo*. Of Sakháwí we possess a bibliographical work on the historians. The polymath Soyúṭí (d. 911) contributed a *History of the Caliphs* and many biographical pieces. Samhúdí’s *History of Medina* is known through the excerpts of Wüstenfeld (1861). Ibn Iyás (d. 930) wrote a *History of Egypt*, and Díyárbekrí (d. 966) a *Life of Mohammed*. To these names must be added MAḲḲARI (*q.v.*) and Hájji Khalífa, the famous Turkish bibliographer (d. 1068), who, besides his *Bibliographical Lexicon* and his well-known geography, the *Jihán-numa*, wrote histories, mostly in Turkish. He made use of European sources, and with him Arabic historiography may be said to cease, though he had some unimportant successors.

A word must be said of the historical romances, the beginnings of which go back to the first centuries of Islam. The interest in all that concerned Mohammed and in the allusions of the Koran to old prophets and races led many professional narrators to choose these subjects in place of the doughty deeds of the Bedouins. The increasing veneration paid to the Prophet and love for the marvellous soon gave rise to fables about his childhood, his visit to heaven, etc., which have found their way even into sober histories, just as many Jewish legends told by the converted Jew Ka‘b al-Aḥbár and by Wahb ibn Monabbih, and many fables about the old princes of Yemen told by ‘Abíd, are taken as genuine history (see, however, Mas‘údí, iv. 88 *sq.*). A fresh field for romantic legend was found in the history of the victories of Islam, the exploits of the first heroes of the faith, the fortunes of ‘Alí and his house. Even under the first Omayyads there were in the mosques of most great cities preachers who edified the people by stories about Islam and its victories, and there is ample evidence that these men did not stick to actual fact. Sho‘ba said of them “they get from us a handbreadth of tradition and make it an ell.” Then, too, history was often expressly forged for party ends. The people swallowed all this, and so a romantic tradition sprang up side by side with the historical, and had a literature of its own, the beginnings of which must be placed as early as the second century of the Flight. The oldest samples still extant are the fables about the conquest of Spain ascribed to Ibn Ḥabíb (d. 238), and those about the conquest of Egypt and the West by Ibn ‘Abdal-ḥakam (d. 257). In these truth and falsehood are mingled, as Dozy has shown in his *Recherches*. But most of the extant literature of this kind is, in its present form, much more recent; *e.g.*, the *Story of the Death of Ḥosain* by the Pseudo-Abú Mikhnaf (translated by Wüstenfeld); the *Conquest of Syria* by Abú Ismá‘íl al-Baçri (edited by Nassau Lees, Calcutta, 1854, and discussed by De Goeje, 1864); the Pseudo-Wáḳidí (see Hamaker, *De Expugnatione Memphidis et Alexandriæ*, Leyden, 1835); the Pseudo-Ibn Ḳotaiba (see Dozy, *Recherches*); the book ascribed to A‘sam Kúfí, etc. Further inquiry into the origin of these works is called for, but some of them were plainly directed to stir up fresh zeal against the Christians. In the 6th century some of these books had gained so much authority that they were used as sources, and thus many untruths crept into accepted history. (M. J. DE G.)

TABERNACLE, the portable sanctuary of Israel in the wilderness wanderings. Critical analysis of the PENTATEUCH (*q.v.*) teaches us to draw a sharp line between the old notices of the tabernacle contained in the pre-Deuteronomic history book (JE) and the account given by the post-exilic priestly narrator. The latter throws back into the time of Moses the whole scheme of worship and ritual of which the second temple was the centre, and, as this scheme necessarily implies the existence of an elaborate sanctuary on the pattern of the temple, he describes a tabernacle of extraordinary splendor pitched in the middle of the camp, with an outer and inner chamber and a courtyard, and all the apparatus of sacrificial and atoning ritual, just as in the temple, only constructed of boards, posts, and curtains so that it could be taken down and moved from place to place. The whole description is ideal, as appears not only from the details but from the fact that the old history knows nothing of such a structure. The Chronicler indeed, who had before him the Pentateuch in its present shape, assumes that after the Israelites entered Canaan the tabernacle continued to be the one legitimate place of sacrifice until it was superseded by Solomon’s temple, and represents it as standing at Gibeon in the days of David and his son (1 Chron. xxi. 29 *sq.*; 2 Chron. i. 3). But the book of Kings knows Gibeon only as “the greatest high place” (1 Kings iii. 4).[1]

Again, the tabernacle of the Priestly Code is preeminently the sanctuary of the ark, bearing the name *mishkan hā‘ēdūth*, “the tabernacle of the testimony,” *i.e.*, the habitation in which lay “the ark of the testimony” or chest containing the stones on which the decalogue was inscribed. But between Joshua’s days and the building of the temple the ark migrated from one tent or habitation to another (2 Sam. vii. 6; 1 Chron. xvii. 5), and at Shiloh it was housed not in a tent but in a temple (1 Sam. iii. 3, 15). And, while in the Priestly Code the tabernacle is the only legitimate sanctuary and its priests are the only legitimate priests, the whole history shows that no such restriction was even thought of till after the time of the prophet Isaiah.

With all this it agrees that the oldest parts of the Pentateuch speak indeed of a tabernacle, but one of a quite different kind. The tabernacle of the Elohist (for of the two narratives—Elohistic and Jahvistic—which are combined in the so-called Jehovistic history only the former seems to mention it) is a tent which Moses pitched outside the camp (Exod. xxxiii. 7 *sq.*), and where Jehovah was wont to reveal Himself to him in the pillar of cloud, which descended for the purpose and stood at the door (Num. xi. 25; xii. 5; xiv. 10); it is therefore called *ōhel mō‘ēd*, “the tent of tryst.” No description of it is given, nor is its origin spoken of, but something of the old narrative has obviously been lost before Exod. xxxiii. 7, and here what is lacking was probably explained. It appears, however, that it was very different from the tabernacle described by the priestly narrator. It was not in the centre of the camp but stood some distance outside it,[1] and it was not the seat of an elaborate organization of priests and guarded by a host of Levites, but had a single minister and custodian, viz., Joshua, who was not a Levite at all but Moses' attendant (Exod. xxxiii. 11).

---

[1] Two passages in the old history, which comprises the books of Judges, Samuel, and Kings, speak of the tabernacle (*ōhel mō‘ēd*); but external and internal evidence show them to be interpolated (1 Sam. ii. 22; 1 Kings viii. 4).

The existence of such a simple tent sanctuary presents none of the difficulties that beset the priestly narrative. Portable shrines were familiar to Semitic antiquity, and tents as sanctuaries were known to the Israelites in much later times at the high places and in connection with irregular worships (Ezek. xvi. 16, "thou didst take of thy garments and madest for thyself sewn high places," *i.e.*, shrines of curtains sewn together; 2 Kings xxiii. 7, where for "hangings for the grove" read "tents for the Ashera"; comp. Hos. ix. 6 and Syriac *prakk*, Assyrian *parakku*, a small chapel or shrine, from the same root as Hebrew *pārōketh*, the vail of the Holy of Holies). Such idolatrous tabernacles were probably relics of the usages of the nomadic Semites, and it is only natural that Israel in its wanderings should have had the like. And it is noteworthy that the portable chapels of the heathen Semites were mainly used for divination (comp. *Journ. of Philol.*, xiii. 283 *sq.*), just as the Mosaic tabernacle is described by the Elohist not as a place of sacrifice (such as the tabernacle of the Priestly Code is) but as a place of oracle.

The heathen shrines of this sort contained portable idols or baetylia (see Selden, *De Diis Syriis*, i. 6); but what the Mosaic tabernacle contained is not expressly told. The ordinary and seemingly the easiest assumption is that the ark stood in it, and Deut. x. 1 *sq.*, which must be drawn from the lost part of the older narrative already alluded to, certainly places the construction of the ark, to contain the tables of stone, just before the time when the tabernacle is first mentioned by the Elohist. But neither in Deuteronomy nor before it are the ark and the tabernacle ever mentioned together, and of the two old narrators it is not clear that the Jahvist ever mentions the tabernacle or the Elohist the ark. The relation between the two calls for further investigation, especially as the ark retains its importance after the occupation of Canaan, while the "tent of tryst" is not mentioned after the time of Moses, who, according to the Elohist (Exod. xii.), enjoyed at it a privilege of direct access to the Deity not accorded to later prophets.

TABERNACLES, Feast of. The original character of this Hebrew feast, celebrated at the close of the agricultural year as a thanksgiving for the produce of the seasons, but especially for the vintage and olive harvest, has been explained in Pentateuch, vol. xviii. p. 522. As such it is described in the old law of Exod. xxiii. 16, under the name of "the feast of ingathering, at the end of the year" (which, in the old Hebrew calendar, ran from autumn to autumn), "when thou hast gathered in thy labors out of the field" (comp. Exod. xxxiv. 22). The same feast is spoken of in Deut. xvi. 13 as "the feast of booths" (E.V. "tabernacles," whence the current name of the feast), when "thou hast gathered in thy corn and wine" from the corn-floor and the wine-press. No explanation is here given of the name "feast of booths"; but after the exile it was understood that during this feast the people assembled at Jerusalem were to live in booths constructed of branches of trees (Lev. xxiii. 39 *sq.*; Neh. viii. 14 *sq.*). The passage in Nehemiah, describing the celebration of the feast in 444 B.C., serves as a commentary on the post-exilic law in Leviticus, and from it we learn that the use of booths on that occasion had no foundation in traditional usage, but was based directly on the law, which then for the first time became generally known.[2] According to the law in question, the booths were to be a memorial of the wilderness wandering (Lev. xxiii. 43), but of this there is no hint in Deuteronomy; and, while it is quite in the style of the later law to attach a new historical reference to an old name like "feast of booths," it is certain from Exodus that the feast had originally agricultural and not historical significance. As such it is exactly parallel to the vintage feasts of other ancient nations, *e.g.*, to the Athenian Oschophoria. And, in particular, it is noteworthy that in Judges ix. 27 we find a vintage feast at Shechem among the Canaanites, from whom the Israelites first learned the ways of agricultural life, and from whom so much of the popular religion was copied. To acts of worship nominally addressed to Jehovah, but really to the Canaanite Baalim, Hosea expressly reckons rites celebrated "on all corn-floors" (ix. 1), expressing thanks for divine gifts of corn, wine, and oil (ii. 8 *sq.*), and in their context these allusions leave no doubt that the prophet refers, in part at least, to autumn feasts, in which Jehovah worship was mingled with Canaanite elements (comp. Wellhausen, *Prol. zur Gesch. Isr.*, cap. 3, ii.; Eng. trans., p. 92 *sq.*). These feasts were local in character, but in northern Israel there was a great autumn feast at the royal sanctuary at Bethel (1 Kings xii. 33), as even in the days of Solomon there was such a feast at Jerusalem (1 Kings viii. 2). In the nature of things the local feasts were the older, and it was the fame of great shrines that gradually tended to draw worshippers from a distance to temples like those of Jerusalem and Bethel. Finally, the Deuteronomic law of the one sanctuary and the course of events which made that law the practical rule of the remnant of Israel put an end to all local religious feasts, but at the same time obscured the old significance of the festal cycle, and made room for the historical interpretation of the celebrations, now concentrated at the temple, which prevailed among the later Jews (comp. Passover and Pentecost). In their later form all the yearly feasts have exact times and rules. In Deuteronomy the autumn feast is not yet tied to a day—it could hardly be so while it was still essentially a harvest thanksgiving—but in the priestly legislation it is fixed to commence on the fifteenth day of the seventh month (Lev. xxiii. 34). In Deuteronomy the feast lasts seven days; Lev. xxiii. 36 adds an eighth, and this day ultimately became the most important (John vii. 37).

If we accept the conclusion that the autumn festival was originally a vintage feast celebrated in local sanctuaries, the name "feast of booths" admits of a natural explanation. The Canaanite feast at Shechem and the Hebrew feast at Shiloh (Judges xxi. 21) were partly celebrated abroad in the vineyards, and Hosea also knows such feasts on the open corn-floors. That it was usual to go forth and live in booths during the vintage may be concluded from Isa. i. 8; the same practice still prevails at Hebron (Robinson, *Bibl. Res.*, ii. 81). If it was these booths erected among the vineyards that originally gave their name to the feast, we can understand how the book of Nehemiah recognizes the erection of booths within the city of Jerusalem as an innovation. No doubt at all feasts where there was a great concourse of visitors many would be compelled to live in tents; this seems to have been the case even in old Israel (Hos. xii. 9). But that is quite a different thing from the later observance, in which booths or bowers had to be made and used even by those who had houses of their own.

TABLES, Mathematical. In any table the results tabulated are termed the "tabular results" or "respondents," and the corresponding numbers by which the table is entered are termed the "arguments." A table is said to be of single or double entry according as there are one or two arguments. For example, a table of logarithms is a table of single entry, the numbers being the arguments and the logarithms the tabular results; an ordinary multipli-

---

[1] In old Israel the sanctuary, after the people had settled down in cities, usually stood outside the town, and this was the case even with the temple at Jerusalem when it was first built.

[2] The expression that the Israelites had not done so since the days of Joshua means that there was no recollection of their having ever done so; for of course it is assumed that Joshua carried out every direction of the law.

Value of tables.

cation table is a table of double entry, giving xy as tabular result for x and y as arguments. The intrinsic value of a table may be estimated by the actual amount of time saved by consulting it; for example, a table of square roots to ten decimals is more valuable than a table of squares, as the extraction of the root would occupy more time than the multiplication of the number by itself. The value of a table does not depend upon the difficulty of calculating it; for, once made, it is made forever, and as far as the user is concerned the amount of labor devoted to its original construction is immaterial. In some tables the labor required in the construction is the same as if all the tabular results had been calculated separately; but in the majority of instances a table can be formed by expeditious methods which are inapplicable to the calculation of an individual result. This is the case with tables of a continuous quantity, which may frequently be constructed by differences. The most striking instance perhaps is afforded by a factor table or a table of primes; for, if it is required to determine whether a given number is prime or not, the only available method (in the absence of tables) is to divide it by every prime less than its square root or until one is found that divides it without remainder. But to form a table of prime numbers the process is theoretically simple and rapid, for we have only to range all the numbers in a line and strike out every second beginning from two, every third beginning from three, and so on, those that remain being primes. Even when the tabular results are constructed separately, the method of differences or other methods connecting together different tabular results may afford valuable verifications. By having recourse to tables not only does the computer save time and labor but he also obtains the certainty of accuracy; in fact, even when the tabular results are so easy to calculate that no time or mental effort would be saved by the use of a table, the certainty of accuracy might make it advantageous to employ it.

The invention of logarithms in 1614, followed immediately by the calculation of logarithmic tables, revolutionized all the methods of calculation; and the original work performed by Briggs and Vlacq in calculating logarithms 260 years ago has in effect formed a portion of every arithmetical operation that has since been carried out by means of logarithms. And not only has an incredible amount of labor been saved[1] but a vast number of calculations and researches have been rendered practicable which otherwise would have been quite beyond human reach. The mathematical process that underlies the tabular method of obtaining a result may be indirect and complicated; for example, the logarithmic method would be quite unsuitable for the multiplication of two numbers if the logarithms had to be calculated specially for the purpose and were not already tabulated for use. The arrangement of a table on the page and all typographical details—such as the shape of the figures, their spacing, the thickness and placing of the rules, the color and quality of the paper, etc.—are of the highest importance, as the computer has to spend hours with his eyes fixed upon the book; and the efforts of eye and brain required in finding the right numbers amidst a mass of figures on a page and in taking them out accurately, when the computer is tired as well as when he is fresh, are far more trying than the mechanical action of simple reading. Moreover, the trouble required by the computer to *learn* the use of a table need scarcely be considered; the important matter is the time and labor saved by it after he has learned its use. Tables are, as a rule, intended for professional and not amateur use; and it is of little moment whether the user who is unfamiliar with a table has to spend ten seconds or a minute in obtaining an isolated result, provided it can be used rapidly and without risk of error by a skilled computer.

In the following description of tables an attempt is made to give an account of all those that a computer of the present day is likely to use in carrying out arithmetical calculations. Tables of merely bibliographical or historical interest are not regarded as coming within the scope of this article, although for special reasons such tables are briefly noticed in some cases. Tables relating to ordinary arithmetical operations are first described, and afterwards an account is given of the most useful and least technical of the more strictly mathematical tables, such as factorials, gamma functions, integrals, Bessel's functions, etc. It is difficult to classify the tables described in a perfectly satisfactory manner without prolixity, as many collections contain valuable sets belonging to a variety of classes. Nearly all modern tables are stereotyped, and in giving their titles the accompanying date is either that of the original stereotyping or of the *tirage* in question. In tables that have passed through many editions the date given is that of the edition described. A much fuller account of general tables published previously to 1872, by the present writer, is contained in the British Association *Report* for 1873, pp. 1–175; and to this the reader is referred.

Divisors and primes.

Tables of Divisors (*Factor Tables*) *and Tables of Primes.*—The existing factor tables extend to 9,000,000. In 1811 Chernac published at Deventer his *Cribrum Arithmeticum*, which gives all the prime divisors of every number not divisible by 2, 3, or 5 up to 1,020,000. In 1814–17 Burckhardt published at Paris his *Tables des Diviseurs*, giving the least divisor of every number not divisible by 2, 3, or 5 up to 3,036,000. The second million was issued in 1814, the third in 1816, and the first in 1817. The corresponding tables for the seventh (in 1862), eighth (1863), and ninth (1865) millions were calculated by Dase and issued at Hamburg. Dase died suddenly during the progress of the work, and it was completed by Rosenberg. Dase's calculation was performed at the instigation of Gauss, and he began at 6,000,000 because the Berlin Academy was in possession of a manuscript presented by Crelle extending Burckhardt's tables from 3,000,000 to 6,000,000. This manuscript, not having been published by 1877, was found on examination to be so inaccurate that the publication was not desirable, and accordingly the three intervening millions were calculated and published by James Glaisher, the *Factor Table for the Fourth Million* appearing at London in 1879, and those for the fifth and sixth millions in 1880 and 1883 respectively (all three millions stereotyped). The tenth million, though calculated by Dase and Rosenberg, has not been published. It is in the possession of the Berlin Academy, having been presented in 1878. The nine quarto volumes (*Tables des Diviseurs*, Paris, 1814–17; *Factor Tables*, London, 1879–83; *Factoren-Tafeln*, Hamburg, 1862–65) thus form one uniform table, giving the least divisor of every number not divisible by 2, 3, or 5, from unity to nine millions. The arrangement of the results on the page, which is due to Burckhardt, is admirable for its clearness and condensation, the least factors for 9000 numbers being given on each page. The tabular portion of each million occupies 112 pages. The first three millions were issued separately, and also bound in one volume, but the other six millions are all separate. Burckhardt began with the second million instead of the first, as Chernac's factor table for the first million was already in existence. Burckhardt's first million does not supersede Chernac's, as the latter gives all the prime divisors of numbers not divisible by 2, 3, or 5 up to 1,020,000. It occupies 1020 pages, and Burckhardt found it very accurate; he detected only thirty-eight errors, of which nine were due to the author, the remaining twenty-nine having been caused by the slipping of type in the printing. The errata thus discovered are given in the first million. Burckhardt gives but a very brief account of the method by which he constructed his table; and the introduction to Dase's millions merely consists of Gauss's letter suggesting their construction. The Introduction to the *Fourth Million* (pp. 52) contains a full account of the method of construction and a history of factor tables, with a bibliography of writings on the subject. The Introduction (pp. 103) to the *Sixth Million* contains an enumeration of primes and a great number of tables relating to the distribution of primes in the whole nine millions, portions of which had been published in the *Cambridge Philosophical Proceedings* and elsewhere. The factor tables which have been described greatly exceed in both extent and accuracy any others of the same kind, the largest of which only reaches 408,000. This is the limit of Felkel's *Tafel aller einfachen Factoren* (Vienna, 1776), a remarkable and extremely rare book,[1] nearly all the copies having been destroyed. Vega (*Tabulæ*, 1797) gave a table showing all the divisors of numbers not divisible by 2, 3, or 5 up to 102,000, followed by a list of primes from 102,000 to 400,313. In the earlier editions of this work there are several errors in the list, but these are no doubt corrected in Hülsse's edition (1840). These are the largest and most convenient tables after those of Chernac. Salomon (1827) gives a factor table to 102,011, Köhler (*Handbuch*, 1848) all divisors up to 21,524, and Houël (*Tables de Logarithmes*, 1871) least divisors up to 10,841. Barlow (*Tables*, 1814) gives the complete resolution of every number up to 10,000 into its factors; for example, corresponding to 4932 we have given $2^2 . 3^2 . 137$. This table is unique so far as we know. The work also contains a list of primes up to 100,103. Both these tables are omitted in the stereotyped reprint of 1840. In *Rees's Cyclopædia* (1819), article "Prime Numbers," there is a list of primes to 217,219 arranged in decades. The *Fourth Million* (1879) contains a list of primes up to 30,341. On the first page of the *Second Million* Burckhardt gives the first nine multiples of the primes to 1423; and a smaller table of the same kind, extending only to 313, occurs in Lambert's *Supplementa*.

---

[1] Referring to factor tables, Lambert wrote (*Supplementa Tabularum*, 1798, p. xv.): "Universalis finis talium tabularum est ut semel pro semper computetur quod sæpius de novo computandum foret, et ut pro omni casu computetur quod in futurum pro quovis casu computatum desiderabitur." This applies to all tables.

Multiplication.

Multiplication Tables.—A multiplication table is usually of double entry, the two arguments being the two factors; when so arranged it is frequently called a Pythagorean table. The largest and most useful work is Crelle's *Rechentafeln* (stereotyped, Bremiker's edition, 1864), which gives in one volume all the products up to 1000 × 1000, so arranged that all the multiples of any one number appear on the same page. The original edition was published in 1820 and consisted of two thick octavo volumes. The second (stereotyped) edition is a convenient folio volume of 450 pages. Only one other multiplication table of the same extent has appeared, viz., Herwart von Hohenburg's *Tabulæ Arithmeticæ Προσθαφαιρέσεως Universales*[2] (Munich, 1610), on which see NAPIER, vol. xvii. p. 188. The invention of logarithms four years later afforded another means of performing multiplications, and Von Hohenburg's work never became generally known. The three following tables are for the multiplication of a number by a single digit. (1) Crelle, *Erleichterungs-Tafel für jeden, der zu rechnen hat* (Berlin, 1836), a work extending to 1000 pages, gives the product of a number of seven figures by a single digit, by means of a double operation of entry. Each page is divided into two tables: for example, to multiply 9382477 by 7 we turn to page 825, and enter the right-hand table at line 77, column 7, where we find 77339; we then enter the left-hand table on the same page at line 93, column 7, and find 656, so that the product required is 65677339. (2) Bretschneider, *Produktentafel* (Hamburg and Gotha, 1841), is somewhat similar to Crelle's table, but smaller, the number of figures in the multiplicand being five instead of seven. (3) In Laundy, *A Table of Products* (London, 1865), the product of any five-figure number by a single digit is given by a double arrangement. The extent of the table is the same as that of Bretschneider's, as also is the principle, but the arrangement is different, Laundy's table occupying only 10 pages and Bretschneider's 99 pages. Among earlier works may be noticed Gruson, *Grosses Einmaleins von Eins bis Hunderttausend* (Berlin, 1799),—a table of products up to 9 × 10,000. The author's intention was to extend it to 100,000, but we believe only the first part was published. In this book there is no condensation or double arrangement; the pages are very large, each containing 125 lines.

Quarter-squares.

Quarter-Squares.—Multiplication may be performed by means of a table of single entry in the manner indicated by the formula—

$$ab = \tfrac{1}{4}(a+b)^2 - \tfrac{1}{4}(a-b)^2.$$

Thus with a table of quarter-squares we can multiply together any two numbers by subtracting the quarter-square of their difference from the quarter-square of their sum. The largest table of quarter-squares is Laundy, *Table of Quarter-Squares of all Numbers up to* 100,000 (London, 1856). Smaller works are Centnerschwer, *Neuerfundene Multiplications- und Quadrat-Tafeln* (Berlin, 1825), which extends to 20,000, and Merpaut, *Tables Arithmonomiques* (Vannes, 1832), which extends to 40,000. In Merpaut's work the quarter-square is termed the "arithmone." Ludolf, who published in 1690 a table of squares to 100,000 (see next paragraph), explains in his introduction how his table may be used to effect multiplications by means of the above formula; but the earliest book on quarter-squares is Voisin, *Tables des Multiplications, ou logarithmes des nombres entiers depuis* 1 *jusqu'à* 20,000 (Paris, 1817). By a logarithm Voisin means a quarter-square, *i.e.*, he calls a a root and $\frac{1}{4}a^2$ its logarithm. On the subject of quarter-squares, etc., see the paper (already referred to) in *Phil. Mag.*, November, 1878.

Squares, cubes, etc.

Squares, Cubes, etc.—The most convenient table for general use, as well as the most extensive, is Barlow's *Tables* (Useful Knowledge Society, London, from the stereotyped plates of 1840), which gives squares, cubes, square roots, cube roots, and reciprocals to 10,000. The largest table of squares and cubes is Kulik, *Tafeln der Quadrat- und Kubik-Zahlen* (Leipsic, 1848), which gives both as far as 100,000. Two early tables also give squares as far as 100,000, viz., Maginus, *Tabula Tetragonica* (Venice, 1592), and Ludolf, *Tetragonometria Tabularia* (Amsterdam, 1690). Hutton, *Tables of Products and Powers of Numbers* (London, 1781), gives squares up to 25,400, cubes to 10,000, and the first ten powers of the first hundred numbers. Barlow, *Mathematical Tables* (original edition, London, 1814), gives the first ten powers of the first hundred numbers. The first nine or ten powers are given in Vega, *Tabulæ* (1797), and in Hülsse's edition of the same (1840), in Köhler, *Handbuch* (1848), and in other collections. Faà de Bruno, *Calcul des Erreurs* (Paris, 1869), and Müller, *Vierstellige Logarithmen* (1844), give squares for use in connection with the method of least squares. Small tables occur frequently in books intended for engineers and practical men. Drach (*Messenger of Math.*, vol. vii., 1878, p. 87) has given to 33 places the cube roots (and the cube roots of the squares) of primes up to 127. Small tables of powers of 2, 3, 5, 7 occur in various collections. In Vega's *Tabulæ* (1797, and the subsequent editions, including Hülsse's) the powers of 2, 3, 5 as far as the 45th, 36th, and 27th respectively are given; they also occur in Köhler's *Handbuch* (1848). The first 25 powers of 2, 3, 5, 7 are given in Salomon, *Logarithmische Tafeln* (1827). Shanks, *Rectification of the Circle* (1853), gives powers of 2 up to 2^{721}.

Triangular numbers.

Triangular Numbers.—É. de Joncourt, *De Natura et Præclaro Usu Simplicissimæ Speciei Numerorum Trigonalium* (The Hague, 1762), contains a table of triangular numbers up to 20,000: viz. $\frac{1}{2}n(n+1)$ is given for all numbers from $n=1$ to 20,000. The table occupies 224 pages.

Reciprocals.

Reciprocals.—Barlow's *Tables* give reciprocals up to 10,000 to 9 or 10 places; and they have been carried to ten times this extent by Oakes, *Table of the Reciprocals of Numbers from* 1 *to* 100,000 (London, 1865). This gives seven figures of the reciprocal, and is arranged like a table of seven-figure logarithms, differences being added at the side of the page. The reciprocal of a number of five figures is therefore taken out at once, and two more figures may be interpolated for as in logarithms. Picarte, *La Division réduite à une Addition* (Paris, 1861), gives to ten significant figures the reciprocals of the numbers from 10,000 to 100,000, and also the first nine multiples of these reciprocals. Small tables of reciprocals are not common.

Vulgar fractions as decimals.

Tables for the Expression of Vulgar Fractions as Decimals.—Tables of this kind have been given by Wucherer, Goodwyn, and Gauss. Wucherer, *Beyträge zum allgemeinern Gebrauch der Decimalbrüche* (Carlsruhe, 1796), gives the decimal fraction (to 5 places) for all vulgar fractions whose numerator and denominator are each less than 50 and prime to one another, arranged according to denominators. The most extensive and elaborate tables that have been published are contained in Henry Goodwyn's *First Centenary of Tables of all Decimal Quotients* (London, 1816), *A Tabular Series of Decimal Quotients* (1823), and *A Table of the Circles arising from the Division of a Unit or any other Whole Number by all the Integers from* 1 *to* 1024 (1823). The *Tabular Series* (1823), running to 153 pages, gives to 8 places the decimal corresponding to every vulgar fraction less than $\frac{99}{991}$ whose numerator and denominator do not surpass 1000. The arguments are not arranged according to their numerators or denominators, but according to their magnitude, so that the tabular results exhibit a steady increase from .001 ($=\frac{1}{1000}$) to .09989909 ($=\frac{99}{991}$). The author intended the table to include all fractions whose numerator and denominator were each less than 1000, but no more was ever published. The *Table of Circles* (1823) gives all the periods of the circulating decimals that can arise from the division of any integer by another integer less than 1024. Thus for 13 we find $.\dot{0}7692\dot{3}$ and $.\dot{1}5384\dot{6}$, which are the only periods in which the fraction $\frac{x}{13}$ can circulate. The table occupies 107 pages, some of the periods being of course very long (*e.g.*, for 1021 the period contains 1020 figures). The *First Centenary* (1816) gives the complete periods of the reciprocals of the numbers from 1 to 100. Goodwyn's tables are very scarce, but as they are nearly unique of their kind they deserve special notice. A second edition of the *First Centenary* was issued in 1818 with the addition of some of the *Tabular Series*, the numerator not exceeding 50 and the denominator not exceeding 100. A posthumous table of Gauss's, entitled "Tafel zur Verwandlung gemeiner Brüche mit Nennern aus dem ersten Tausend in Decimalbrüche," occurs in vol. ii. pp. 412–434 of his *Gesammelte Werke* (Göttingen, 1863), and resembles Goodwyn's *Table of Circles*. On this subject see a paper "On Circulating Decimals, with special reference to Henry Goodwyn's *Table of Circles* and *Tabular Series of Decimal Quotients*," in *Camb. Phil. Proc.*, vol. iii. (1878), pp. 185–206, where is also given a table of the periods of fractions corresponding to denominators prime to 10 from 1 to 1024 obtained by counting from Goodwyn's table. See also the section on "Circulating Decimals," p. 18 below.

---

[1] For information about it, see a paper on "Factor Tables," in *Camb. Phil. Proc.*, vol. iii. (1878) pp. 99–138, or the introduction to the *Fourth Million*.

[2] See a paper "On Multiplication by a Table of Single Entry," in *Phil. Mag.*, November, 1878, for a notice of this book.

Sexagesimal and sexcentenary.

Sexagesimal and Sexcentenary Tables.—Originally all calculations were sexagesimal; and the relics of the system still exist in the division of the degree into 60 minutes and the minute into 60 seconds. To facilitate interpolation, therefore, in trigonometrical and other tables the following large sexagesimal tables were constructed. John Bernoulli, *A Sexcentenary Table* (London, 1779), gives at once the fourth term of any proportion of which the first term is 600″ and each of the other two is less than 600″; the table is of double entry, and may be more fully described as giving the value of $\frac{xy}{600}$ correct to tenths of a second, x and y each containing a number of seconds less than 600. Michael Taylor, *A Sexagesimal Table* (London, 1780), exhibits at sight the fourth term of any proportion where the first term is 60 minutes, the second any number of minutes less than 60, and the third any number of minutes and seconds under 60 minutes; there is also another table in which the third term is any absolute number under 1000. Not much use seems to have been made of these tables, both of which were published by the Commissioners of Longitude. Small tables for the conversion of sexagesimals into centesimals and *vice versa* are given in a few collections, such as Hülsse's edition of Vega.

Trigonometrical.

Trigonometrical Tables (Natural).—Peter Apian published in 1533 a table of sines with the radius divided decimally. The first complete canon giving all the six ratios of the sides of a right-angled triangle is due to Rheticus (1551), who also introduced the semi-quadrantal arrangement. Rheticus's canon was calculated for every ten minutes to 7 places, and Vieta extended it to every minute (1579). In 1554 Reinhold published a table of tangents to every minute. The first complete canon published in England was by Blunedvile (1594), although a table of sines had appeared four years earlier. Regiomontanus called his table of tangents (or rather cotangents) *tabula fœcunda* on account of its great use; and till the introduction of the word "tangent" by Finck (*Geometriæ Rotundi Libri XIV.*, Basel, 1583) a table of tangents was called a *tabula fœcunda* or *canon fœcundus*. Besides "tangent," Finck also introduced the word "secant," the table of secants having previously been called *tabula benefica* by Maurolycus (1558) and *tabula fœcundissima* by Vieta.

By far the greatest computer of pure trigonometrical tables is George Joachim Rheticus, whose work has never been superseded. His celebrated ten-decimal canon, the *Opus Palatinum*, was published by Valentine Otho at Neustadt in 1596, and in 1613 his fifteen-decimal table of sines by Pitiscus at Frankfort under the title *Thesaurus Mathematicus*. The *Opus Palatinum* contains a complete ten-decimal trigonometrical canon for every ten seconds of the quadrant, semiquadrantally arranged, with differences for all the tabular results throughout. Sines, cosines, and secants are given on the left-hand pages in columns headed respectively "Perpendiculum," "Basis," "Hypotenusa," and on the right-hand appear tangents, cosecants, and cotangents in columns headed respectively "Perpendiculum," "Hypotenusa," "Basis." At his death Rheticus left the canon nearly complete, and the trigonometry was finished and the whole edited by Valentine Otho; it was named in honor of the elector palatine Frederick IV., who bore the expense of publication. The *Thesaurus* of 1613 gives natural sines for every ten seconds throughout the quadrant, to 15 places, semiquadrantally arranged, with first, second, and third differences. Natural sines are also given for every second from 0° to 1° and from 89° to 90°, to 15 places, with first and second differences. The rescue of the manuscript of this work by Pitiscus forms a striking episode in the history of mathematical tables. The alterations and emendations in the earlier part of the corrected edition of the *Opus Palatinum* were made by Pitiscus, who had his suspicions that Rheticus had himself calculated a ten-second table of sines to 15 decimal places; but it could not be found. Eventually the lost canon was discovered amongst the papers of Rheticus, which had passed from Otho to James Christmann on the death of the former. Amongst these Pitiscus found (1) the ten-second table of sines to 15 places, with first, second, and third differences (printed in the *Thesaurus*); (2) sines for every second of the first and last degrees of the quadrant, also to 15 places, with first and second differences; (3) the commencement of a canon of tangents and secants, to the same number of decimal places, for every ten seconds, with first and second differences; (4) a complete minute canon of sines, tangents, and secants, also to 15 decimal places. These tables taken in connection with the *Opus Palatinum* give an idea of the enormous labors undertaken by Rheticus; his tables not only remain to this day the ultimate authorities but formed the data whereby Vlacq calculated his logarithmic canon. Pitiscus says that for twelve years Rheticus constantly had computers at work.

A history of trigonometrical tables by Hutton was prefixed to all the early editions of his *Tables of Logarithms*, and forms Tract xix. of his *Mathematical Tracts*, vol. i. pp. 278–306, 1812. A good deal of bibliographical information about the *Opus Palatinum* and earlier trigonometrical tables is given in De Morgan's article "Tables" in the *English Cyclopædia*. The invention of logarithms the year after the publication of Rheticus's volume by Pitiscus changed all the methods of calculation; and it is worthy of note that Napier's original table of 1614 was a logarithmic canon of sines and not a table of the logarithms of numbers. The logarithmic canon at once superseded the natural canon; and since Pitiscus's time no really extensive table of pure trigonometrical functions has appeared. In recent years the employment of the arithmometer of Thomas de Colmar has revived the use of tables of natural trigonometrical functions, it being found convenient for some purposes to employ an arithmometer and a natural canon instead of a logarithmic canon. Junge's *Tafel der wirklichen Länge der Sinus und Cosinus* (Leipsic, 1864) was published with this object. It gives natural sines and cosines for every ten seconds of the quadrant to 6 places. F. M. Clouth, *Tables pour le Calcul des Coordonnées Goniométriques* (Mainz, n.d.), gives natural sines and cosines (to 6 places) and their first nine multiples (to 4 places) for every centesimal minute of the quadrant. Tables of natural functions occur in many collections, the natural and logarithmic values being sometimes given on opposite pages, sometimes side by side on the same page.

The following works contain tables of trigonometrical functions other than sines, cosines, and tangents. Pasquich, *Tabulæ Logarithmico-Trigonometricæ* (Leipsic, 1817), contains a table of $\sin^2 x$, $\cos^2 x$, $\tan^2 x$, $\cot^2 x$ from $x = 1°$ to 45° at intervals of 1′ to 5 places. Andrew, *Astronomical and Nautical Tables* (London, 1805), contains a table of "squares of natural semichords," *i.e.*, of $\sin^2 \frac{1}{2}x$ from $x = 0°$ to 120° at intervals of 10″ to 7 places. This table has recently been greatly extended by Major-General Hannyngton in his *Haversines, Natural and Logarithmic, used in computing Lunar Distances for the Nautical Almanac* (London, 1876). The name "haversine," now frequently used in works upon navigation, is an abbreviation of "half versed sine;" viz., the haversine of x is equal to $\frac{1}{2}(1 - \cos x)$, that is, to $\sin^2 \frac{1}{2}x$. The table gives logarithmic haversines for every 15″ from 0° to 180°, and natural haversines for every 10″ from 0° to 180°, to 7 places, except near the beginning, where the logarithms are given to only 5 or 6 places. The work itself occupies 327 folio pages, and was suggested by Andrew's, a copy of which by chance fell into Hannyngton's hands. Hannyngton recomputed the whole of it by a partly mechanical method, a combination of two arithmometers being employed. A table of haversines is useful for the solution of spherical triangles when two sides and the included angle are given, and in many other problems in spherical trigonometry. Andrew's original table seems to have attracted very little notice. Hannyngton's was printed, on the recommendation of the superintendent of the *Nautical Almanac* office, at the public cost. Before the calculation of Hannyngton's table Farley's *Natural Versed Sines* (London, 1856) was used in the *Nautical Almanac* office in computing lunar distances. This fine table contains natural versed sines from 0° to 125° at intervals of 10″ to 7 places, with proportional parts, and log versed sines from 0° to 135° at intervals of 15″ to 7 places. The arguments are also given in time. The manuscript was used in the office for twenty-five years before it was printed. Traverse tables, which occur in most collections of navigation tables, contain multiples of sines and cosines.

Common or Briggian logarithms.

Common or Briggian Logarithms of Numbers and Trigonometrical Ratios.—For an account of the invention and history of logarithms, see LOGARITHMS (vol. xiv. p. 779) and NAPIER. The following are the fundamental works which contain the results of the original calculations of logarithms of numbers and trigonometrical ratios: Briggs, *Arithmetica Logarithmica* (London, 1624), logarithms of numbers from 1 to 20,000 and from 90,000 to 100,000 to 14 places, with interscript differences; Vlacq, *Arithmetica Logarithmica* (Gouda, 1628, also an English edition, London, 1631, the tables being the same), ten-figure logarithms of numbers from 1 to 100,000, with differences, also log sines, tangents, and secants for every minute of the quadrant to 10 places, with interscript differences; Vlacq, *Trigonometria Artificialis* (Gouda, 1633), log sines and tangents to every ten seconds of the quadrant to 10 places, with differences, and ten-figure logarithms of numbers up to 20,000, with differences; Briggs, *Trigonometria Britannica* (London, 1633), natural sines to 15 places, tangents and secants to 10 places, log sines to 14 places, and tangents to 10 places, at intervals of a hundredth of a degree from 0° to 45°, with interscript differences for all the functions. In 1794 Vega reprinted at Leipsic Vlacq's two works in a single folio volume, *Thesaurus Logarithmorum Completus.* The arrangement of the table of logarithms of numbers is more compendious than in Vlacq, being similar to that of an ordinary seven-figure table, but it is not so convenient, as mistakes in taking out the differences are more liable to occur. The trigonometrical canon gives log sines, cosines, tangents, and cotangents, from 0° to 2° at intervals of one second, to 10 places, without differences, and for the rest of the quadrant at intervals of ten seconds. The trigonometrical canon is not wholly reprinted from the *Trigonometria Artificialis,* as the logarithms for every second of the first two degrees, which do not occur in Vlacq, were calculated for the work by Lieutenant Dorfmund. Vega devoted great attention to the detection of errors in Vlacq's logarithms of numbers, and has given several important errata lists. M. Lefort (*Annales de l'Observatoire de Paris,* vol. iv.) has given a full errata list in Vlacq's and Vega's logarithms of numbers, obtained by comparison with the great French manuscript *Tables du Cadastre* (see LOGARITHMS, vol. xiv. p. 783; comp. also *Monthly Notices of Roy. Ast. Soc.* for May, 1872, June, 1872, March, 1873, and 1874, suppl. number). Vega seems not to have bestowed on the trigonometrical canon anything like the care that he devoted to the logarithms of numbers, as Gauss[1] estimates the total of last-figure errors at from 31,983 to 47,746, most of them only amounting to a unit, but some to as much as 3 or 4. As these errors in the *Trigonometria Artificialis* still remain uncorrected, it cannot be said that a reliable ten-place logarithmic trigonometrical canon exists. The calculator who has occasion to perform work requiring ten-figure logarithms of numbers should use Vlacq's *Arithmetica Logarithmica* of 1628, after carefully correcting the errors pointed out by Vega and Lefort. After Vlacq, Vega's *Thesaurus* is the next best table; and Pineto's *Tables de Logarithmes Vulgaires à Dix Décimales, construites d'après un nouveau mode* (St. Petersburg, 1871), though a tract of only 80 pages, may be usefully employed when Vlacq and Vega are unprocurable. Pineto's work consists of three tables: the first, or auxiliary table, contains a series of factors by which the numbers whose logarithms are required are to be multiplied to bring them within the range of table 2; it also gives the logarithms of the reciprocals of these factors to 12 places. Table 1 merely gives logarithms to 1000 to 10 places. Table 2 gives logarithms from 1,000,000 to 1,011,000, with proportional parts to hundredths. The mode of using these tables is as follows. If the logarithm cannot be taken out directly from table 2, a factor M is found from the auxiliary table by which the number must be multiplied to bring it within the range of table 2. Then the logarithm can be taken out, and, to neutralize the effect of the multiplication, so far as the result is concerned, $\log\left(\frac{1}{M}\right)$ must be added; this quantity is therefore given in an adjoining column to M in the auxiliary table. A similar procedure gives the number answering to any logarithm, another factor (approximately the reciprocal of M) being given, so that in both cases multiplication is used. The laborious part of the work is the multiplication by M; but this is somewhat compensated for by the ease with which, by means of the proportional parts, the logarithm is taken out. The factors are 300 in number, and are chosen so as to minimize the labor, only 25 of the 300 consisting of three figures all different and not involving 0 or 1. The principle of multiplying by a factor which is subsequently cancelled by subtracting its logarithm is used also in a tract, containing only ten pages, published by MM. Namur and Mansion at Brussels in 1877 under the title *Tables de Logarithmes à 12 décimales jusqu'à 434 milliards.* Here a table is given of logarithms of numbers near to 434,294, and other numbers are brought within the range of the table by multiplication by one or two factors. The logarithms of the numbers near to 434,294 are selected for tabulation because their differences commence with the figures 100 . . . and the presence of the zeros in the difference renders the interpolation easy.

If seven-figure logarithms do not give sufficiently accurate results, it is usual to have recourse to ten-figure tables; with one exception, there exist no tables giving 8 or 9 figures. The exception is John Newton's *Trigonometria Britannica* (London, 1658), which gives logarithms of numbers to 100,000 to 8 places, and also log sines and tangents for every centesimal minute (*i.e.*, the nine thousandth part of a right angle), and also log sines and tangents for the first three degrees of the quadrant to 5 places, the interval being the one-thousandth part of a degree. This table is also unique in that it gives the logarithms of the differences instead of the actual differences. The arrangement of the page now universal in seven-figure tables—with the fifth figures running horizontally along the top line of the page—is due to John Newton.

As a rule seven-figure logarithms of numbers are not published separately, most tables of logarithms containing both the logarithms of numbers and a trigonometrical canon. Babbage's and Sang's logarithms are exceptional and give logarithms of numbers only. Babbage, *Table of the Logarithms of the Natural Numbers from* 1 *to* 108,000 (London, stereotyped in 1827; there are several tirages of later dates), is the best for ordinary use. Great pains were taken to get the maximum of clearness. The change of figure in the middle of the block of numbers is marked by a change of type in the fourth figure, which (with the sole exception of the asterisk) is the best method that has been used. Copies of the book were printed on paper of different colors—yellow, brown, green, etc.—as it was considered that black on a white ground was a fatiguing combination for the eye. The tables were also issued with title-pages and introductions in other languages. The book is not very easy to procure now. In 1871 Mr. Sang published *A New Table of Seven-place Logarithms of all Numbers from* 20,000 *to* 200,000 (London). In an ordinary table extending from 10,000 to 100,000 the differences near the beginning are so numerous that the proportional parts are either very crowded or some of them omitted; by making the table extend from 20,000 to 200,000 instead of from 10,000 to 100,000 the differences are halved in magnitude, while there are only one-fourth as many in a page. There is also greater accuracy. A further peculiarity of this table is that multiples of the differences, instead of proportional parts, are given at the side of the page. Typographically the table is exceptional, as there are no rules, the numbers being separated from the logarithms by reversed commas. This work was to a great extent the result of an original calculation; see *Edinburgh Transactions,* vol. xxvi. (1871). Mr. Sang proposed to publish a nine-figure table from 1 to 1,000,000, but the requisite support was not obtained. Various papers of Mr. Sang's relating to his logarithmic calculations will be found in the *Edinburgh Proceedings* subsequent to 1872. In this connection reference should be made to Abraham Sharp's table of logarithms of numbers from 1 to 100 and of primes from 100 to 1100 to 61 places, also of numbers from 999,990 to 1,000,010 to 63 places. These first appeared in *Geometry Improv'd . . . by A. S. Philomath* (London, 1717). They have been republished in Sherwin's, Callet's, and the earlier editions of Hutton's tables. Parkhurst, *Astronomical Tables* (New York, 1871), gives logarithms of numbers from 1 to 109 to 102 places.[2]

In many seven-figure tables of logarithms of numbers the values of S and T are given at the top of the page, with V, the variation of each, for the purpose of deducing log sines and tangents. S and T denote $\log\frac{\sin x}{x}$ and $\log\frac{\tan x}{x}$ respectively, the arguments being the number of seconds denoted by certain numbers (sometimes only the first, sometimes every tenth) in the number column on each page. Thus, in Callet's tables, on the page on which the first number is 67,200, $S=\log\frac{\sin 6720''}{6720}$ and $T=\log\frac{\tan 6720''}{6720}$, while the *V*'s are the variations of each for 10″. To find, for example, log sin 1° 52′ 12.7″, or log sin 6732.7″, we have $S=4.6354930$ and log 6732.7 = 3.8281893 whence, by addition, we obtain 8.5136873; but *V* for 10″ is —2.29 whence the variation for 12.7″ is — 3, and the log sine required is 8.5136870. Tables of S and T are frequently called, after their inventor, "Delambre's tables." Some seven-figure tables extend to 100,000, and others to 108,000, the last 8000 logarithms, to 8 places, being given to ensure greater accuracy, as near the beginning of the numbers the differences are large and the interpolations more laborious and less exact than in the rest of the table. The eight-figure logarithms, however, at the end of a seven-figure table are liable to occasion error; for the computer who is accustomed to three leading figures, common to the block of figures, may fail to notice that in this part of the table there are four, and so a figure (the fourth) is sometimes omitted in taking out the logarithm. In the ordinary method of arranging a seven-figure table the change in the fourth figure, when it occurs in the course of the line, is a source of frequent error unless it is very clearly indicated. In the earlier tables the change was not marked at all, and the computer had to decide for himself, each time he took out a logarithm, whether the third figure had to be increased. In some tables the line is broken where the change occurs; but the dislocation of the figures and the corresponding irregularity in the lines are very awkward. Babbage printed the fourth figure in small type after a change. The best method seems to be that of prefixing an asterisk to the fourth figure of each logarithm after the change, as is done in Schrön's and many other modern tables. This is beautifully clear and the asterisk at once catches the eye. Shortrede and Sang replace 0 after a change by a *nokta* (resembling a diamond in a pack of cards). This is very clear in the case of the 0's, but leaves unmarked the cases in which the fourth figure is 1 or 2. Babbage printed a subscript point under the last figure of each logarithm that had been increased. Schrön used a bar subscript, which, being more obtrusive, is not so satisfactory. In some tables the increase of the last figure is only marked when the figure is increased to a 5, and then a Roman five (v) is used in place of the Arabic figure. Hereditary errors in logarithmic tables are considered in two papers "On the Progress to Accuracy of Logarithmic Tables" and "On Logarithmic Tables," in *Monthly Notices of Roy. Ast. Soc.* for 1873. See also the *Monthly Notices* for 1874, p. 248; and a paper by Gernerth, *Ztsch. f. d. österr. Gymn.*, Heft vi. p. 407.

---

[1] See his "Einige Bemerkungen zu Vega's *Thesaurus Logarithmorum,*" in *Astronomische Nachrichten* for 1851 (reprinted in his *Werke,* vol. iii. pp. 257-264); also *Monthly Notices Roy. Ast. Soc.* for May, 1873.

[2] Legendre (*Traité des Fonctions Elliptiques,* vol. ii., 1826) gives a table of natural sines to 15 places, and of log sines to 14 places, for every 15″ of the quadrant, and also a table of logarithms of uneven numbers from 1163 to 1501, and of primes from 1501 to 10,000 to 19 places. The latter, which was extracted from the *Tables du Cadastre,* is a continuation of a table in Gardiner's *Tables of Logarithms* (London, 1742; reprinted at Avignon, 1770), which gives logarithms of all numbers to 1000, and of uneven numbers from 1000 to 1143. Legendre's tables also appeared in his *Exercices de Calcul Intégral,* vol. iii. (1816).

Passing now to the logarithmic trigonometrical canon, the first great advance after the publication of the *Trigonometria Artificialis* in 1633 was made by Michael Taylor, *Tables of Logarithms* (London, 1792), which gives log sines and tangents to every second of the quadrant to 7 places. This table contains about 450 pages with an average number of 7750 figures to the page, so that there are altogether nearly three millions and a half of figures. The change in the leading figures, when it occurs in a column, is not marked at all; and the table must be used with very great caution. In fact it is advisable to go through the whole of it, and fill in with ink the first 0 after the change, as well as make some mark that will catch the eye at the head of every column containing a change. The table was calculated by interpolation from the *Trigonometria Artificialis* to 10 places and then reduced to 7, so that the last figure should always be correct. Partly on account of the absence of a mark to denote the change of figure in the column and partly on account of the size of the table and a somewhat inconvenient arrangement, the work seems never to have come into very general use. Computers have always preferred Bagay's *Nouvelles Tables Astronomiques et Hydrographiques* (Paris, 1829), which also contains a complete logarithmic canon to every second. The change in the column is very clearly marked by a large black nucleus, surrounded by a circle, printed instead of zero. Bagay's work has now become very rare. The only other canon to every second that has been published is contained in Shortrede's *Logarithmic Tables* (Edinburgh). This work was originally issued in 1844 in one volume, but being dissatisfied with it Shortrede issued a new edition in 1849 in two volumes. The first volume contains logarithms of numbers, antilogarithms, etc., and the second the trigonometrical canon to every second. The volumes are sold separately, and may be regarded as independent works; they are not even described on their title-pages as vol. i. and vol. ii. The trigonometrical canon is very complete in every respect, the arguments being given in time as well as in arc, full proportional parts being added, etc. The change of figure in the column is denoted by a nokta, printed instead of 0 where the change occurs.

Of tables in which the quadrant is divided centesimally, the principal are Hobert and Ideler, *Nouvelles Tables Trigonométriques* (Berlin, 1799), and Borda and Delambre, *Tables Trigonométriques Décimales* (Paris, 1801). The former give, among other tables, natural and log sines, cosines, tangents, and cotangents, to 7 places, the arguments proceeding to 3° at intervals of 10″ and thence to 50° at intervals of 1′ (centesimal), and also natural sines and tangents for the first hundred ten-thousandths of a right angle to 10 places. The latter gives log sines, cosines, tangents, cotangents, secants, and cosecants from 0° to 3° at intervals of 10″ (with full proportional parts for every second), and thence to 50° at intervals of 1′ (centesimal) to 7 places. There is also a table of log sines, cosines, tangents, and cotangents from 0′ to 10′ at intervals of 10″ and from 0° to 50° at intervals of 10′ (centesimal) to 11 places. Hobert and Ideler give a natural as well as a logarithmic canon; but Borda and Delambre give only the latter. Borda and Delambre give seven-figure logarithms of numbers to 10,000, the line being broken when a change of figure takes place in it.

In Briggs's *Trigonometria Britannica* of 1633 the degree is divided centesimally, and but for the appearance in the same year of Vlacq's *Trigonometria Artificialis*, in which the degree is divided sexagesimally, this reform might have been effected. It is clear that the most suitable time for effecting such a change was when the natural canon was replaced by the logarithmic canon, and Briggs took advantage of this opportunity. He left the degree unaltered, but divided it centesimally instead of sexagesimally, thus ensuring the advantages of decimal division (a saving of work in interpolations, multiplications, etc.) with the minimum of change. The French mathematicians at the end of the 18th century divided the right angle centesimally, completely changing the whole system, with no appreciable advantages over Briggs's system. In fact the centesimal degree is as arbitrary a unit as the nonagesimal, and it is only the non-centesimal subdivision of the degree that gives rise to inconvenience. Briggs's example was followed by Roe, Oughtred, and other 17th-century writers; but the centesimal division of the degree seems to have entirely passed out of use, till it was recently revived by Bremiker in his *Logarithmisch-trigonometrische Tafeln mit fünf Decimalstellen* (Berlin, 1872). This little book of 158 pages gives a five-figure canon to every hundredth of a degree with proportional parts, besides logarithms of numbers, addition and subtraction logarithms, etc.

Collections.

Collections of Tables.—For a computer who requires in one volume logarithms of numbers and a ten-second logarithmic canon, perhaps the two best books are Schrön, *Seven-Figure Logarithms* (London, 1865, stereotyped, an English edition of the German work published at Brunswick), and Bruhns, *A New Manual of Logarithms to Seven Places of Decimals* (Leipsic, 1870). Both give logarithms of numbers and a complete ten-second canon to 7 places; Bruhns also gives log sines, cosines, tangents, and cotangents to every second up to 6° with proportional parts. Schrön contains an interpolation table, of 75 pages, giving the first 100 multiples of all numbers from 40 to 420. The logarithms of numbers extend to 108,000 in Schrön and to 100,000 in Bruhns. Almost equally convenient is Bremiker's edition of Vega's *Logarithmic Tables* (Berlin, stereotyped; the English edition was translated from the fortieth edition of Dr. Bremiker's by W. L. F. Fischer). This book gives a canon to every ten seconds, and for the first five degrees to every second, with logarithms of numbers to 100,000. All these works give the proportional parts for all the differences in the logarithms of numbers. In Babbage's, Callet's, and many other tables only every other table of proportional parts is given near the beginning for want of space. Schrön, Bruhns, and most modern tables published in Germany have title-pages and introductions in different languages. Dupuis, *Tables de Logarithmes à sept Décimales* (stereotyped, third tirage, 1868, Paris), is also very convenient, containing a ten-second canon, besides logarithms of numbers to 100,000, hyperbolic logarithms of numbers to 1000, to 7 places, etc. In this work negative characteristics are printed throughout in the tables of circular functions, the minus sign being placed above the figure; these are preferable to the ordinary characteristics that are increased by 10. This is the only work we know in which negative characteristics are used. The edges of the pages containing the circular functions are red, the rest being gray. Dupuis also edited Callet's logarithms in 1862, with which this work must not be confounded. Salomon, *Logarithmische Tafeln* (Vienna, 1827), contains a ten-second canon (the intervals being one second for the first two degrees), logarithms of numbers to 108,000, squares, cubes, square roots, and cube roots to 1000, a factor table to 102,011, ten-place Briggian and hyperbolic logarithms of numbers to 1000 and of primes to 10,333, and many other useful tables.* The work, which is scarce, is a well-printed small quarto volume.

Of collections of general tables the most useful and accessible are Hutton, Callet, Vega, and Köhler. Hutton's well-known *Mathematical Tables* (London) was first issued in 1785, but considerable additions were made in the fifth edition (1811). The tables contain seven-figure logarithms to 108,000, and to 1200 to 20 places, some antilogarithms to 20 places, hyperbolic logarithms from 1 to 10 at intervals of .01 and to 1200 at intervals of unity to 7 places, logistic logarithms, log sines and tangents to every second of the first two degrees, and natural and log sines, tangents, secants, and versed sines for every minute of the quadrant to 7 places. The natural functions occupy the left-hand pages and the logarithmic the right-hand. The first six editions, published in Hutton's lifetime (d. 1823), contain Abraham Sharp's 61-figure logarithms of numbers. Olinthus Gregory, who brought out the 1830 and succeeding editions, omitted these tables and Hutton's introduction, which contains a history of logarithms, the methods of constructing them, etc. Callet's *Tables Portatives de Logarithmes* (stereotyped, Paris) seems to have been first issued in 1783, and has since passed through a great many editions. In that of 1853 the contents are seven-figure logarithms to 108,000, Briggian and hyperbolic logarithms to 48 places of numbers to 100 and of primes to 1097, log sines and tangents for minutes (centesimal) throughout the quadrant to 7 places, natural and log sines to 15 places for every ten minutes (centesimal) of the quadrant, log sines and tangents for every second of the first five degrees (sexagesimal) and for every ten seconds of the quadrant (sexagesimal) to 7 places, besides logistic logarithms, the first hundred multiples of the modulus to 24 places and the first ten to 70 places, and other tables. This is one of the most complete and practically useful collections of logarithms that have been published, and it is peculiar in giving a centesimally divided canon. The size of the page in the editions published in the 19th century is larger than that of the earlier editions, the type having been reset. Vega's *Tabulæ Logarithmo-trigonometricæ* was first published in 1797 in two volumes. The first contains seven-figure logarithms to 101,000, log sines, etc., for every tenth of a second to 1′, for every second to 1° 30′, for every 10″ to 6° 3′, and thence at intervals of a minute, also natural sines and tangents to every minute, all to 7 places. The second volume gives simple divisors of all numbers up to 102,000, a list of primes from 102,000 to 400,313, hyperbolic logarithms of numbers to 1000 and of primes to 10,000, to 8 places, e^x and $\log_{10}e^x$ to $x = 10$ at intervals of .01 to 7 figures and 7 places respectively, the first nine powers of the numbers from 1 to 100, squares and cubes to 1000, logistic logarithms, binomial theorem coefficients, etc. Vega also published *Manuale Logarithmico-trigonometricum* (Leipsic, 1800), the tables in which are identical with a portion of those contained in the first volume of the *Tabulæ*. The *Tabulæ* went through many editions, a stereotyped issue being brought out by J. A. Hülsse (*Sammlung mathematischer Tafeln*, Leipsic) in one volume in 1840. The contents are nearly the same as those of the original work, the chief difference being that a large table of Gaussian logarithms is added. Vega differs from Hutton and Callet in giving so many useful non-logarithmic tables, and his collection is in many respects complementary to theirs. Schulze, *Neue und erweiterte Sammlung logarithmischer, trigonometrischer, und anderer Tafeln* (Berlin, 1778, 2 vols.), is a valuable collection, and contains seven-figure logarithms to 101,000, log sines and tangents to 2° at intervals of a second, and natural sines, tangents, and secants to 7 places, log sines and tangents and Napierian log sines and tangents to 8 places, all for every ten seconds to 4° and thence for every minute to 45°, besides squares, cubes, square roots, and cube roots to 1000, binomial theorem coefficients, powers of *e*, and other small tables. Wolfram's hyperbolic logarithms of numbers below 10,000 to 48 places first appeared in this work. Lambert, *Supplementa Tabularum Logarithmicarum et Trigonometricarum* (Lisbon, 1798), contains a number of useful and curious non-logarithmic tables; it bears a general resemblance to the second volume of Vega, but contains numerous other small tables of a more strictly mathematical character. A very useful collection of non-logarithmic tables is printed in Barlow's *New Mathematical Tables* (London, 1814). It gives squares, cubes, square roots, and cube roots (to 7 places), reciprocals to 9 or 10 places, and resolutions into their prime factors of all numbers from 1 to 10,000, the first ten powers of numbers to 100, fourth and fifth powers of numbers from 100 to 1000, prime numbers from 1 to 100,103, eight-place hyperbolic logarithms to 10,000, tables for the solution of the irreducible case in cubic equations, etc. In the stereotyped reprint of 1840 only the squares, cubes, square roots, cube roots, and reciprocals are retained. The first volume of Shortrede's tables, in addition to the trigonometrical canon to every second, contains antilogarithms and Gaussian logarithms. Hassler, *Tabulæ Logarithmicæ et Trigonometricæ* (New York, 1830, stereotyped), gives seven-figure logarithms to 100,000, log sines and tangents for every second to 1°, and log sines, cosines, tangents, and cotangents from 1° to 3° at intervals of 10″ and thence to 45° at intervals of 30″. Every effort has been made to reduce the size of the tables without loss of distinctness, the page being only about 3 by 5 inches. Copies of the work were published with the introduction and title-page in different languages. Stanley, *Tables of Logarithms* (New Haven, U. S., 1860), gives seven-figure logarithms to 100,000, and log sines, cosines, tangents, cotangents, secants, and cosecants at intervals of ten seconds to 15° and thence at intervals of a minute to 45° to 7 places, besides natural sines and cosines, antilogarithms, and other tables. This collection owed its origin to the fact that Hassler's tables were found to be inconvenient owing to the smallness of the type. Luvini, *Tables of Logarithms* (London, 1866, stereotyped, printed at Turin), gives seven-figure logarithms to 20,040, Briggian and hyperbolic logarithms of primes to 1200 to 20 places, log sines and tangents for each second to 9′, at intervals of 10″ to 2°, of 30″ to 9°, of 1′ to 45° to 7 places, besides square and cube roots up to 625. The book, which is intended for schools, engineers, etc., has a peculiar arrangement of the logarithms and proportional parts on the pages. Chambers's *Mathematical Tables* (Edinburgh), containing logarithms of numbers to 100,000, and a canon to every minute of log sines, tangents, and secants and of natural sines to 7 places, besides proportional logarithms and other small tables, is cheap and suitable for schools, though not to be compared as regards matter or typography to the best tables described above. Of six-figure tables Bremiker's *Logarithmorum VI. Decimalium Nová Tabula Berolinensis* (Berlin, 1852) is probably one of the best. It gives logarithms of numbers to 100,000, with proportional parts, and log sines and tangents for every second to 5°, and beyond this point for every ten seconds, with proportional parts. Hantschl, *Logarithmisch-trigonometrisches Handbuch* (Vienna, 1827), gives five-figure logarithms to 10,000, log sines and tangents for every ten seconds to 6 places, natural sines, tangents, secants, and versed sines for every minute to 7 places, logarithms of primes to 15,391, hyperbolic logarithms of numbers to 11,273 to 8 places, least divisors of numbers to 18,277, binomial theorem coefficients, etc. Farley's *Six-Figure Logarithms* (London, stereotyped, 1840) gives six-figure logarithms to 10,000 and log sines and tangents for every minute to 6 places. Of five-figure tables the most convenient is *Tables of Logarithms* (Useful Knowledge Society, London, from the stereotyped plates of 1839), which were prepared by De Morgan, though they have no name on the title-page. They contain five-figure logarithms to 10,000, log sines and tangents to every minute to 5 places, besides a few smaller tables. Lalande's *Tables de Logarithmes* is a five-figure table with nearly the same contents as De Morgan's, first published in 1805. It has since passed through many editions, and, after being extended from 5 to 7 places, passed through several more. Galbraith and Haughton, *Manual of Mathematical Tables* (London, 1860), give five-figure logarithms to 10,000 and log sines and tangents for every minute, also a small table of Gaussian logarithms. Houël, *Tables de Logarithmes à Cinq Décimales* (Paris, 1871), is a very convenient collection of five-figure tables; besides logarithms of numbers and circular functions, there are Gaussian logarithms, least divisors of numbers to 10,841, antilogarithms, etc. The work contains 118 pages of tables. The same author's *Recueil de Formules et de Tables Numériques* (Paris, 1868) contains 19 tables, occupying 62 pages, most of them giving results to 4 places; they relate to very varied subjects,—antilogarithms, Gaussian logarithms, logarithms of $\frac{1+x}{1-x}$, elliptic integrals, squares for use in the method of least squares, etc. Bremiker, *Tafel vierstelliger Logarithmen* (Berlin, 1874), gives four-figure logarithms of numbers to 2009, log sines, cosines, tangents, and cotangents to 8° for every hundredth of a degree, and thence to 45° for every tenth of a degree, to 4 places. There are also Gaussian logarithms, squares from 0.000 to 13,500, antilogarithms, etc. The book contains 60 pages. Willich, *Popular Tables* (London, 1853), is a useful book for an amateur; it gives Briggian and hyperbolic logarithms to 1200 to 7 places, squares, etc., to 343, etc.

Napierian logarithms.

Hyperbolic or Napierian Logarithms.—The logarithms invented by Napier and explained by him in the *Descriptio* (1614) were not the same as those now called natural or hyperbolic (viz., to base *e*), and very frequently also Napierian, logarithms. Napierian logarithms, strictly so called, have entirely passed out of use and are of purely historic interest; it is therefore sufficient to refer to LOGARITHMS and NAPIER, where a full account is given. Apart from the inventor's own publications, the only Napierian tables of importance are contained in Ursinus's *Trigonometria* (Cologne, 1624–1625) and Schulze's *Sammlung* (Berlin, 1778), the former being the largest that has been constructed. Logarithms to the base e, where e denotes 2.71828, were first published by Speidell, *New Logarithmes* (1619).

Hyperbolic logarithms.

The most copious table of hyperbolic logarithms is Dase, *Tafel der natürlichen Logarithmen* (Vienna, 1850), which extends from 1 to 1000 at intervals of unity and from 1000 to 10,500 at intervals of .1 to 7 places, with differences and proportional parts, arranged as in an ordinary seven-figure table. By adding log 10 to the results the range is from 10,000 to 105,000 at intervals of unity. The table formed part of the *Annals of the Vienna Observatory* for 1851, but separate copies were printed. The most elaborate table of hyperbolic logarithms is due to Wolfram, who calculated to 48 places the logarithms of all numbers up to 2200, and of all primes (also of a great many composite numbers) between this limit and 10,009. Wolfram's results first appeared in Schulze's *Sammlung* (1778). Six logarithms which Wolfram had been prevented from computing by a serious illness were supplied in the *Berliner Jahrbuch*, 1783, p. 191. The complete table was reproduced in Vega's *Thesaurus* (1794), when several errors were corrected. Tables of hyperbolic logarithms are contained in the following collections: Callet, all numbers to 100 and primes to 1097 to 48 places; Borda and Delambre (1801), all numbers up to 1200 to 11 places; Salomon (1827), all numbers to 1000 and primes to 10,333 to 10 places; Vega, *Tabulæ* (including Hülsse's edition, 1840), and Köhler (1848), all numbers to 1000 and primes to 10,000 to 8 places; Barlow (1814), all numbers to 10,000; Hutton and Willich (1853), all numbers to 1200 to 7 places; Dupuis (1868), all numbers to 1000 to 7 places. Hutton also gives hyperbolic logarithms from 1 to 10 at intervals of .01 to 7 places. *Rees's Cyclopædia* (1819), art. "Hyperbolic Logarithms," contains a table of hyperbolic logarithms of all numbers up to 10,000 to 8 places.

Conversion of Briggian and hyperbolic logarithms.

Tables to convert Briggian into Hyperbolic Logarithms, and vice versa.—Such tables merely consist of the first hundred (sometimes only the first ten) multiples of the modulus .43429 44819 . . . and its reciprocal 2.30258 50929 . . . to 5, 6, 8, 10, or more places. They are generally to be found in collections of logarithmic tables, but rarely exceed a page in extent, and are very easy to construct. Schrön and Bruhns both give the first hundred multiples of the modulus and its reciprocal to 10 places, and Bremiker (in his edition of Vega and in his six-figure tables) and Dupuis to 7 places. Degen, *Tabularum Enneas* (Copenhagen, 1824), gives the first hundred multiples of the modulus to 30 places.

Antilogarithms.

Antilogarithms.—In the ordinary tables of logarithms the natural numbers are integers, while the logarithms are incommensurable. In an antilogarithmic canon the logarithms are exact quantities, such as .00001, .00002, etc., and the corresponding numbers are incommensurable. The largest and earliest work of this kind is Dodson's *Antilogarithmic Canon* (London, 1742), which gives numbers to 11 places corresponding to logarithms from 0 to 1 at intervals of .00001, arranged like a seven-figure logarithmic table, with interscript differences and proportional parts at the bottom of the page. This work was the only antilogarithmic canon for more than a century, till in 1844 Shortrede published the first edition of his tables: in 1849 he published the second edition, and in the same year Filipowski's tables appeared. Both these works contain seven-figure antilogarithms: Shortrede gives numbers to logarithms from 0 to 1 at intervals of .00001, with differences and multiples at the top of the page, and Filipowski, *A Table of Antilogarithms* (London, 1849), contains a table of the same extent, the proportional parts being given to hundredths.

Gaussian logarithms.

Addition and Subtraction, or Gaussian Logarithms.—The object of such tables is to give log $(a \pm b)$ by only one entry when log a and log b are given (see LOGARITHMS, vol. xiv. p. 784). Let

$$A = \log x, \qquad B = \log\left(1 + \frac{1}{x}\right), \qquad C = \log(1 + x).$$

Leaving out the specimen table in Leonelli's *Théorie des Logarithmes Additionnels et Déductifs* (Bordeaux, 1803), the principal tables are the following: Gauss, in Zach's *Monatliche Correspondenz* (1812), giving B and C for argument A from 0 to 2 at intervals of .001, thence to 3.40 at intervals of .01, and to 5 at intervals of .1, all to 5 places. This table is reprinted in Gauss's *Werke*, vol. iii. p. 244. Matthiessen, *Tafel zur bequemern Berechnung* (Altona, 1818), giving B and C to 7 places for argument A from 0 to 2 at intervals of .0001, thence to 3 at intervals of .001, to 4 at intervals of .01, and to 5 at intervals of .1; the table is not conveniently arranged. Peter Gray, *Tables and Formulæ* (London, 1849, and "Addendum," 1870), giving C for argument A from 0 to 2 at intervals of .0001 to 6 places, with proportional parts to hundredths, and log $(1-x)$ for argument A from 3 to 1 at intervals of .001 and from 1 to 1.9 at intervals of .0001, to 6 places, with proportional parts. Zech. *Tafeln der Additions- und Subtractions- Logarithmen* (Leipsic, 1849), giving B for argument A from 0 to 2 at intervals of .0001, thence to 4 at intervals of .001 and to 6 at intervals of 01; also C for argument A from 0 to .0003 at intervals of .0000001, thence to .05 at intervals of .000001 and to .303 at intervals of .00001, all to 7 places, with proportional parts. These tables are reprinted from Hülsse's edition of Vega (1849); the 1840 edition of Hülsse's Vega contained a reprint of Gauss's original table. Wittstein, *Logarithmes de Gauss à Sept Décimales* Hanover, 1866), giving B for argument A from 3 to 4 at intervals of .1, from 4 to 6 at intervals of .01, from 6 to 8 at intervals of .001, from 8 to 10 at intervals of .0001, also from 0 to 4 at the same intervals. In this handsome work the arrangement is similar to that in a seven-figure logarithmic table. Gauss's original five-place table was reprinted in Pasquich, *Tabulæ* (Leipsic, 1817); Köhler, *Jerome de la Lande's Tafeln* (Leipsic, 1832), and *Handbuch* (Leipsic, 1848); and Galbraith and Haughton, *Manual* (London, 1860). Houël, *Tables de Logarithmes* (1871), also gives a small five-place table of Gaussian logarithms, the addition and subtraction logarithms being separated as in Zech. Modified Gaussian logarithms are given by J. H. T. Müller, *Vierstellige Logarithmen* (Gotha, 1844), viz., a four-place table of B and $-\log\left(1-\frac{1}{x}\right)$ from $A=0$ to .03 at intervals of .0001, thence to .23 at intervals of .001, to 2 at intervals of .01, to 4 at intervals of .1; and by Shortrede, *Logarithmic Tables* (vol.i., 1849), viz., a five-place table of B and log $(1+x)$ from $A=5$ to 3 at intervals of .1, from $A=\bar{3}$ to $\bar{2}.7$ at intervals of .01, to 1.3 at intervals of .001, to 3 at intervals of .01, and to 5 at intervals of .1. Filipowski's *Antilogarithms* (1849) contains Gaussian logarithms arranged in a new way. The principal table gives log $(x+1)$ as tabular result for log x as argument from 8 to 14 at intervals of .001 to 5 places. Weidenbach, *Tafeln um den Logarithmen* (Copenhagen, 1829), gives $\log\frac{x+1}{x-1}$ for argument A from .382 to 2.002 at intervals of .001, to 3.6 at intervals of .01, and to 5.5 at intervals of .1, to 5 places.

Logistic and proportional logarithms.

Logistic and Proportional Logarithms.—In most collections of tables of logarithms a five-place table of logistic logarithms for every second to 1° is given. Logistic tables give log 3600 − log x at intervals of a second, x being expressed in degrees, minutes, and seconds; Schulze (1778) and Vega (1797) have them to $x=3600''$ and Callet and Hutton to $x=5280''$. Proportional logarithms for every second to 3° (*i.e.*, log 10,800 − log x) form part of nearly all collections of tables relating to navigation, generally to 4 places, sometimes to 5. Bagay, *Tables* (1829), gives a five-place table, but such are not often to be found in collections of mathematical tables. The same remark applies to tables of proportional logarithms for every minute to 24^h, which give to 4 or 5 places the values of log 1440 − log x. The object of a proportional or logistic table, or a table of log a − log x, is to facilitate the calculation of proportions in which the third term is a.

Interpolation tables.

Interpolation Tables.—All tables of proportional parts may be regarded as interpolation tables. Bremiker, *Tafel der Proportionaltheile* (Berlin, 1843), gives proportional parts to hundredths of all numbers from 70 to 699. Schrön, *Logarithms*, contains an interpolation table giving the first hundred multiples of all numbers from 40 to 410. Tables of the values of binomial theorem coefficients, which are required when second and higher orders of differences are used, are described below. Woolhouse, *On Interpolation, Summation, and the Adjustment of Numerical Tables* (London, 1865), contains nine pages of interpolation tables. The book consists of papers extracted from vols. xi. and xii. of the *Assurance Magazine.*

Dual logarithms.

Dual Logarithms.—This term is used by Mr. Oliver Byrne in his *Dual Arithmetic, Young Dual Arithmetician, Tables of Dual Logarithms*, etc. (London, 1863–67). A dual number of the ascending branch is a continued product of powers of 1.1, 1.01, 1.001, etc., taken in order, the powers only being expressed; thus ↓6,9,7,8 denotes $(1.1)^6(1.01)^9(1.001)^7(1.0001)^8$, the numbers following the ↓ being called dual digits. A dual number which has all but the last digit zeros is called a dual logarithm; the author uses dual logarithms in which there are seven ciphers between the ↓ and the logarithms. A dual number of the descending branch is a continued product of powers of .9, .99, etc.: for instance, $(.9)^3(.99)^2$ is denoted by '3 '2↑. The *Tables*, which occupy 112 pages, give dual numbers and logarithms, both of the ascending and descending branches, and the corresponding natural numbers. The author claimed that his tables were superior to those of common logarithms.

Constants.

Constants.—In nearly all tables of logarithms there is a page devoted to certain frequently used constants and their logarithms, such as $\pi, \frac{1}{\pi}, \pi^2, \sqrt{\pi}$. A specially good collection is printed in Templeton's *Millwright's and Engineer's Pocket Companion* (corrected by S. Maynard, London, 1871), which gives 58 constants involving π and their logarithms, generally to 30 places, and 13 others that may be properly called mathematical. A good list of constants involving π is given in Salomon (1827). A paper by Paucker in *Grunert's Archiv* (vol. i. p. 9) has a number of constants involving π given to a great many places, and Gauss's memoir on the lemniscate function (*Werke*, vol. iii.) has $e^{-\pi}$, $e^{-\frac{1}{4}\pi}$, $e^{-\frac{9}{4}}$, etc., calculated to about 50 places. The quantity π has been worked out to 707 places (Shanks, *Proc. Roy. Soc.*, vol. xxi. p. 319) and Euler's constant to 263 places (Adams, *Proc. Roy. Soc.*, vol. xxvii. p. 88). The value of the modulus *M*, calculated by Prof. Adams, is given in LOGARITHMS, vol. xiv. p. 785. This value is correct to 263 places; but the calculation has since been carried to 272 places (see Adams, *Proc. Roy. Soc.*, vol. xlii. p. 22, 1887).

Irreducible cubic equations.

Tables for the Solution of the Irreducible Case in Cubic Equations.—Lambert, *Supplementa* (1798), gives $\pm(x-x^3)$ from $x = .001$ to 1.155 at intervals of .001 to 7 places, and Barlow (1814) gives x^3-x from $x = 1$ to 1.1549 at intervals of .0001 to 8 places.

Binomial theorem coefficients.

Binomial Theorem Coefficients.—The values of

$$\frac{x(x-1)}{1.2}, \frac{x(x-1)(x-2)}{1.2.3}, \ldots \frac{x(x-1)\ldots(x-5)}{1.2\ldots6},$$

from $x = .01$ to $x = 1$ at intervals of .01 to 7 places, are serviceable for use in interpolation by second and higher orders of differences. The table quoted above occurs in Schulze (1778), Barlow (1814), Vega (1797) and succeeding editions), Hantschl (1827), and Köhler (1848). Rouse, *Doctrine of Chances* (London, no date), gives on a folding sheet $(a+b)^n$ for $n = 1, 2, \ldots 20$. Lambert, *Supplementa* (1798), has the coefficients of the first 16 terms in $(1+x)^{\frac{1}{2}}$ and $(1-x)^{\frac{1}{2}}$, their accurate values being given as decimals. Vega (1797) has a page of tables giving $\frac{1}{2.4}, \frac{1.3}{2.4.6}, \ldots \frac{1}{2.3}, \ldots$ and similar quantities to 10 places, with their logarithms to 7 places, and a page of this kind occurs in other collections. Köhler (1848) gives the values of 40 such quantities.

Figurate numbers.

Figurate Numbers.—Lambert, *Supplementa*, gives $x, \frac{x(x+1)}{1.2}, \ldots \frac{x(x+1)\ldots(x+11)}{1.2\ldots12}$ from $x = 1$ to 30.

Trigonometrical quadratic surds.

Trigonometrical Quadratic Surds.—The surd values of the sines of every third degree of the quadrant are given in some tables of logarithms; *e.g.*, in Hutton's (p. xxxix., ed. 1855), we find sin 3° $= \frac{1}{8}\left\{\sqrt{(5+\sqrt{5})} + \sqrt{\frac{15}{2}} + \sqrt{\frac{5}{2}} - \sqrt{(15+3\sqrt{5})} - \sqrt{\frac{3}{2}} - \sqrt{\frac{1}{2}}\right\}$; and the numerical values of the surds $\sqrt{(5+\sqrt{5})}$, $\sqrt{(\frac{15}{2})}$, etc., are given to 10 places. These values were extended to 20 places by Peter Gray, *Messenger of Math.*, vol. vi. (1877), p. 105.

Circulating decimals.

Circulating Decimals.—Goodwyn's tables have been described above, p. 12. Several others have been published giving the number of digits in the periods of the reciprocals of primes; Burckhardt, *Tables des Diviseurs du Premier Million* (Paris, 1814–17), gave one for all primes up to 2543 and for 22 primes exceeding that limit. Desmarest, *Théorie des Nombres* (Paris, 1852), included all primes up to 10,000. Reuschle, *Mathematische Abhandlung, enthaltend neue zahlentheoretische Tabellen* (1856), contains a similar table to 15,000. This Shanks extended to 60,000; the portion from 1 to 30,000 is printed in the *Proc. Roy. Soc.*, vol. xxii. p. 200, and the remainder is preserved in the archives of the society (*Id.*, xxiii. p. 260 and xxiv. p. 392). The number of digits in the decimal period of $\frac{1}{p}$ is the same as the exponent to which 10 belongs for modulus p, so that, whenever the period has $p-1$ digits, 10 is a primitive root of p. Tables of primes having a given number, n, of digits in their periods, *i.e.*, tables of the resolutions of 10^n-1 into factors and, as far as known, into prime factors, have been given by Loof (in *Grunert's Archiv*, vol. xvi. p. 54; reprinted in *Nouv. Annales*, vol. xiv. p. 115) and by Shanks (*Proc. Roy. Soc.*, vol. xxii. p. 381). The former extends to $n = 60$ and the latter to $n = 100$, but there are gaps in both. Reuschle's tract also contains resolutions of 10^n-1. For further references on circulating decimals, see *Proc. Camb. Phil. Soc.*, vol. iii. p. 185 (1878).

Pythagorean triangles.

Pythagorean Triangles.—Right-angled triangles in which the sides and hypothenuse are all rational integers are frequently termed Pythagorean triangles, as, for example, the triangles 3, 4, 5 and 5, 12, 13. Schulze, *Sammlung* (1778), contains a table of such triangles subject to the condition tan $\frac{1}{2}\omega > \frac{1}{25}$ (ω being one of the acute angles). About 100 triangles are given, but some occur twice. Large tables of right-angled rational triangles were given by Bretschneider, in *Grunert's Archiv*, vol. i. p. 96 (1841), and by Sang, *Edinburgh Transactions*, vol. xxiii. p. 727 (1864). In these the triangles are arranged according to hypothenuses and extend to 1201, 1200, 49, and 1105, 1073, 264 respectively. Whitworth, in a paper read before the Lit. and Phil. Society of Liverpool in 1875, carried his list as far as 2465, 2337, 784. See also Rath, "Die rationalen Dreiecke," in *Grunert's Archiv*, vol. lvi. p. 188 (1874). Sang's paper also contains a table of triangles having an angle equal to 120° and their sides integers.

Powers of π.

Powers of π.—Paucker, in *Grunert's Archiv*, vol. i. p. 10, gives π^{-1} and $\pi^{\frac{1}{2}}$ to 140 places, and π^{-2}, $\pi^{-\frac{1}{2}}$, $\pi^{\frac{1}{3}}$, $\pi^{\frac{2}{3}}$ to about 50 places; and in Maynard's list of constants (see "Constants," above) π^2 is given to 31 places. The first twelve powers of π and π^{-1} to 22 or more places were printed by Glaisher, *Proc. Lond. Math. Soc.*, vol. viii. p. 140, and the first hundred multiples of π and π^{-1} to 12 places by Kulik, *Tafel der Quadrat-und Kubik-Zahlen* (Leipsic, 1848).

Series $1^{-n}+2^{-n}$, etc.

The Series $1^{-n}+2^{-n}+3^{-n}+$ etc. Let S_n, s_n, σ_n denote respectively the sums of the series $1^{-n}+2^{-n}+3^{-n}+$ etc., $1^{-n}-2^{-n}+3^{-n}-$ etc., $1^{-n}+3^{-n}+5^{-n}+$ etc. Legendre (*Traité des Fonctions Elliptiques*, vol. ii. p. 432) has computed S_n to 16 places from $n = 1$ to 35, and Glaisher (*Proc. Lond. Math. Soc.*, vol. iv. p. 48) has deduced s_n and σ_n for the same arguments and to the same number of places. The latter has also given S_n, s_n, σ_n for $n = 2, 4, 6, \ldots 12$ to 22 or more places (*Proc. Lond. Math. Soc.*, vol. viii. p. 140), and the values of Σ_n, where $\Sigma_n = 2^{-n}+3^{-n}+5^{-n}+$ etc. (prime numbers only involved), for $n = 2, 4, 6, \ldots 36$ to 15 places (*Compte Rendu de l'Assoc. Française* for 1878, p. 172).

Hyperbolic antilogarithms.

Tables of e^x *and* e^{-x}, *or Hyperbolic Antilogarithms.*—The largest tables are the following. Gudermann, *Theorie der potenzial- oder cyklisch-hyperbolischen Functionen* (Berlin, 1833), which consists of papers reprinted from vols. viii. and ix. of *Crelle's Journal*, and gives $\log_{10}$ sinh x, $\log_{10}$ cosh x, and $\log_{10}$ tanh x from $x = 2$ to 5 at intervals of .001 to 9 places and from $x = 5$ to 12 at intervals of .01 to 10 places. Since sinh $x = \frac{1}{2}(e^x - e^{-x})$ and cosh $x = \frac{1}{2}(e^x + e^{-x})$, the values of e^x and e^{-x} are deducible at once by addition and subtraction. Newman, in *Camb. Phil. Trans.*, vol. xiii. pp. 145–241, gives values of e^{-x} from $x = 0$ to 15.349 at intervals of .001 to 12 places, from $x = 15.350$ to 17.298 at intervals of .002, and from $x = 17.300$ to 27.635 at intervals of .005, to 14 places. Glaisher, in *Camb. Phil. Trans.*, vol. xiii. pp. 243–272, gives four tables of e^x, e^{-x}, $\log_{10} e^x$, $\log_{10} e^{-x}$, their ranges being from $x = .001$ to .1 at intervals of .001, from .01 to 2 at intervals of .01, from .1 to 10 at intervals of .1, from 1 to 500 at intervals of unity. Vega, *Tabulæ* (1797 and later edd.), has $\log_{10} e^x$ to 7 places and e^x to 7 figures from $x = .01$ to 10 at intervals of .01. Köhler's *Handbuch* contains a small table of e^x. In Schulze's *Sammlung* (1778) e^x is given for $x = 1, 2, 3, \ldots 24$ to 28 or 29 figures and for $x = 25, 30$, and 60 to 32 or 33 figures; this table is printed in Glaisher's paper (*loc. cit.*). In Salomon's *Tafeln* (1827) the values of e^n, $e^{.n}$, $e^{.0n}$, $e^{.00n}, \ldots e^{.000000n}$, where n has the values 1, 2, ... 9, are given to 12 places. Bretschneider, in *Grunert's Archiv*, iii. p. 33, worked out e^x and e^{-x} and also sin x and cos x for $x = 1, 2, \ldots 10$ to 20 places.

Factorials.

Factorials.—The values of $\log_{10}(n!)$, where $n!$ denotes $1.2.3\ldots n$, from $n = 1$ to 1200 to 18 places, are given by Degen, *Tabularum Enneas* (Copenhagen, 1824), and reprinted, to 6 places, at the end of De Morgan's article "Probabilities" in the *Encyclopædia Metropolitana*. Shortrede, *Tables* (1849, vol. i.), gives log $(n!)$ to $n = 1000$ to 5 places, and for the arguments ending in 0 to 8 places. Degen also gives the complements of the logarithms. The first 20 figures of the values of $n \times n!$

and the values of $\log_{10}\frac{1}{n\times n!}$ are computed by Glaisher as far as $n=71$ in the *Phil. Trans.* for 1870 (p. 370), and the values of $\frac{1}{n!}$ to 28 significant figures as far as $n=50$ in *Camb. Phil. Trans.*, vol. xiii. p. 246.

Bernoullian numbers.

Bernoullian Numbers.—The first fifteen Bernoullian numbers were given by Euler, *Inst. Calc. Diff.*, part ii. ch. v. Sixteen more were calculated by Rothe, and the first thirty-one were published by Ohm in *Crelle's Journal*, vol. xx. p. 11. Prof. J. C. Adams has calculated the next thirty-one, and a table of the first sixty-two was published by him in the *Brit. Assoc. Report* for 1877 and in *Crelle's Journal*, vol. lxxxv. p. 269. The first nine figures of the values of the first 250 Bernoullian numbers, and their Briggian logarithms to 10 places, have been printed by Glaisher, *Camb. Phil. Trans.*, vol. xii. p. 384.

Tables of log tan $(\frac{1}{4}\pi+\frac{1}{2}\phi)$.

Tables of log tan $(\frac{1}{4}\pi+\frac{1}{2}\phi)$.—Gudermann, *Theorie der potenzial- oder cyklisch-hyperbolischen Functionen* (Berlin, 1833), gives (in 100 pages) log tan $(\frac{1}{4}\pi+\frac{1}{2}\phi)$ for every centesimal minute of the quadrant to 7 places. Another table contains the values of this function, also at intervals of a minute, from 88° to 100° (centesimal) to 11 places. Legendre, *Traité des Fonctions Elliptiques* (vol. ii. p. 256), gives the same function for every half degree (sexagesimal) of the quadrant to 12 places.

Gamma function.

The Gamma Function.—Legendre's great table appeared in vol. ii. of his *Exercices de Calcul Intégral* (1816), p. 85, and in vol. ii. of his *Traité des Fonctions Elliptiques* (1826), p. 489. $\operatorname{Log}_{10}\Gamma(x)$ is given from $x=1$ to 2 at intervals of .001 to 12 places, with differences to the third order. This table is reprinted in full in Schlömilch, *Analytische Studien* (1848), p. 183; an abridgment in which the arguments differ by .01 occurs in De Morgan, *Diff. and Int. Calc.*, p. 587. The last figures of the values omitted are also supplied, so that the full table can be reproduced. A seven-place abridgment (without differences) is published in Bertrand, *Calcul Intégral* (1870), p. 285, and a six-figure abridgment in Williamson, *Integral Calculus* (1884), p. 169. In vol. i. of his *Exercices* (1811), Legendre had previously published a seven-place table of $\log_{10}\Gamma(x)$, without differences.

Elliptic functions.

Tables connected with Elliptic Functions.—Legendre calculated elaborate tables of the elliptic integrals in vol. ii. of *Traité des Fonctions Elliptiques* (1826). Denoting the modular angle by θ, the amplitude by ϕ, and the incomplete integral of the second kind by $E_1(\phi)$ the tables are—(1) $\log_{10} E$ and $\log_{10} K$ from $\theta=0°$ to 90° at intervals of 0.1° to 12 or 14 places, with differences to the third order; (2) $E_1(\phi)$ and $F(\phi)$, the modular angle being 45° from $\phi=0°$ to 90° at intervals of 0.5° to 12 places, with differences to the fifth order; (3) $E_1(45°)$ and $F(45°)$ from $\theta=0°$ to 90° at intervals of 1°, with differences to the sixth order, also E and K for the same arguments, all to 12 places; (4) $E_1(\phi)$ and $F(\phi)$ for every degree of both the amplitude and the argument to 9 or 10 places. The first three tables had been published previously in vol. iii. of the *Exercices de Calcul Intégral* (1816).

Tables involving q.

Tables involving q.—Verhulst, *Traité des Fonctions Elliptiques* (Brussels, 1841), contains a table of $\log_{10}\log_{10}\left(\frac{1}{q}\right)$ for argument θ at intervals of 0.1° to 12 or 14 places. Jacobi, in *Crelle's Journal*, vol. xxvi. p. 93, gives $\log_{10} q$ from $\theta=0°$ to 90° at intervals of 0°.1 to 5 places. Meissel, *Sammlung mathematischer Tafeln*, i. (Iserlohn, 1860), consists of a table of $\log_{10} q$ at intervals of 1′ from $\theta=0°$ to 90° to 8 places. Glaisher, in *Month. Not. Roy. Ast. Soc.*, vol. xxxvii. p. 372 (1877), gives $\log_{10} q$ to 10 places and q to 9 places for every degree. In Bertrand, *Calcul Intégral* (1870), a table of $\log_{10} q$ from $\theta=0°$ to 90° at intervals of 5′ to 5 places is accompanied by tables of $\log_{10}\sqrt{\frac{2K}{\pi}}$ and $\log_{10}\log_{10}\frac{1}{q}$ and by abridgments of Legendre's tables of the elliptic integrals. Schlömilch, *Vorlesungen der höheren Analysis* (Brunswick, 1879), p. 448, gives a small table of $\log_{10} q$ for every degree to 5 places.

Legendrian coefficients.

Legendrian Coefficients.—The values of $P^n(x)$ for $n=1, 2, 3, \ldots 7$ from $x=0$ to 1 at intervals of .01 are given by Glaisher, in *Brit. Assoc. Rep.* for 1879, pp. 54–57. The functions tabulated are $P^1(x)=x$, $P^2(x)=\frac{1}{2}(3x^2-1)$, $P^3(x)=\frac{1}{2}(5x^3-3x)$, $P^4(x)=\frac{1}{8}(35x^4-30x^2+3)$, $P^5(x)=\frac{1}{8}(63x^5-70x^3+15x)$, $P^6(x)=\frac{1}{16}(231x^6-315x^4+105x^2-5)$, $P^7(x)=\frac{1}{16}(429x^7-693x^5+315x^3-35x)$. The functions occur in connection with the theory of interpolation, the attraction of spheroids, and other physical theories.

Bessel's functions.

Bessel's Functions.—Bessel's original table appeared at the end of his memoir "Untersuchung des planetarischen Theils der Störungen, welche aus der Bewegung der Sonne entstehen" (in *Abh. d. Berl. Akad.*, 1824; reprinted in vol. i. of his *Abhandlungen*, p. 84). It gives $J_0(x)$ and $J_1(x)$ from $x=0$ to 3.2 at intervals of .01. More extensive tables were calculated by Hansen in "Ermittelung der absoluten Störungen in Ellipsen von beliebiger Excentricität und Neigung" (in *Schriften der Sternwarte Seeberg*, part i., Gotha, 1843). They include an extension of Bessel's original table to $x=20$, besides smaller tables of $J_n(x)$ for certain values of n as far as $n=28$, all to 7 places. Hansen's table was reproduced by Schlömilch, in *Zeitschr. für Math.*, vol. ii. p. 158, and by Lommel, *Studien über die Bessel'schen Functionen* (Leipsic, 1868), p. 127. Hansen's notation is slightly different from Bessel's; the change amounts to halving each argument. Schlömilch gives the table in Hansen's form; Lommel expresses it in Bessel's.

Sine, etc., integrals.

Sine, Cosine, Exponential, and Logarithm Integrals.—The functions so named are the integrals $\int_0^x\frac{\sin x}{x}dx$, $\int_\infty^x\frac{\cos x}{x}dx$, $\int_{-\infty}^x\frac{e^x}{x}dx$, $\int_0^x\frac{dx}{\log x}$, which are denoted by the functional signs Si x, Ci x, Ei x, li x respectively. Soldner, *Théorie et Tables d'une Nouvelle Fonction Transcendante* (Munich, 1809), gave the values of li x from $x=0$ to 1 at intervals of .1 to 7 places, and thence at various intervals to 1220 to 5 or more places. This table is reprinted in De Morgan's *Diff. and Int. Calc.*, p. 662. Bretschneider, in *Grunert's Archiv*, vol. iii. p. 33, calculated Ei $(\pm x)$, Si x, Ci x for $x=1, 2, \ldots 10$ to 20 places, and subsequently (in Schlömilch's *Zeitschrift*, vol. vi.) worked out the values of the same functions from $x=0$ to 1 at intervals of .01 and from 1 to 7.5 at intervals of .1 to 10 places. Two tracts by L. Stenberg, *Tabulæ Logarithmi Integralis* (Malmö, part i. 1861 and part ii. 1867), give the values of li 10^x from $x=-15$ to 3.5 at intervals of .01 to 18 places. Glaisher, in *Phil. Trans.*, 1870, p. 367, gives Ei $(\pm x)$, Si x, Ci x from $x=0$ to 1 at intervals of .01 to 18 places, from $x=1$ to 5 at intervals of .1 and thence to 15 at intervals of unity, and for $x=20$ to 11 places, besides seven-place tables of Si x and Ci x and tables of their maximum and minimum values. See also Bellavitis, "Tavole Numeriche Logaritmo-Integrale" (a paper in *Memoirs of the Venetian Institute*, 1874). Bessel calculated the values of li 1000, li 10,000, li 100,000, li 200,000, . . . li 600,000, and li 1,000,000 (see *Abhandlungen*, vol. ii. p. 339). In Glaisher, *Factor Table for the Sixth Million* (1883, § iii., the values of li x are given from $x=0$ to 9,000,000 at intervals of 50,000 to the nearest integer.

Values of $\int_0^x e^{-x^2}dx$ and $e^{x^2}\int_0^x e^{-x^2}dx$.

Values of $\int_0^x e^{-x^2}dx$ *and* $e^{x^2}\int_0^x e^{-x^2}dx$.—These functions are employed in researches connected with refractions, theory of errors, conduction of heat, etc. Let $\int_0^x e^{-x^2}dx$ and $\int_x^\infty e^{-x^2}dx$ be denoted by Erf x and Erfc x respectively, standing for, "error function" and "error function complement," so that Erf x + Erfc $x=\frac{1}{2}\sqrt{\pi}$ (*Phil. Mag.*, Dec. 1871; it has since been found convenient to transpose as above the definitions of Erf and Erfc). The tables of the functions, and of the functions multiplied by e^{x^2}, are as follows. Kramp, *Analyse des Réfractions* (Strasburg, 1798), has Efrc x from $x=0$ to 3 at intervals of .01 to 8 or more places, also $\log^{10}$ (Erfc x) and $\log_{10}(e^{x^2}\text{Erfc } x)$ for the same values to 7 places. Bessel, *Fundamenta Astronomiæ* (Königsberg, 1818), has $\log_{10}(e^{x^2}\text{Erfc } x)$ from $x=0$ to 1 at intervals of .01 to 7 places, likewise for argument $\log_{10} x$, the arguments increasing from 0 to 1 at intervals of .01. Legendre, *Traité des Fonctions Elliptiques* (1826), vol. ii. p. 520, contains $\Gamma(\frac{1}{2}, e^{-x^2})$, that is, 2 Erfc x from $x=0$ to .5 at intervals of .01 to 10 places. Encke, *Berliner Ast. Jahrbuch* for 1834, prints $\frac{2}{\sqrt{\pi}}$ Erf x from $x=0$ to 2 at intervals of .01 to 7 places and $\frac{2}{\sqrt{\pi}}$ Erf (ρx) from $x=0$ to 3.4 at intervals of .01 and thence to 5 at intervals of .1 to 5 places, ρ being .4769360. Glaisher, in *Phil. Mag.*, December 1871, has calculated Erfc x from $x=3$ to 4.5 at intervals of .01 to 11, 13, or 14 places. Encke's tables and two of Kramp's were reprinted in the *Encyclopædia Metropolitana*, art. "Probabilities."

Tables of Integrals, not Numerical.—Meyer Hirsch, *Integraltafeln* (1810; Eng. trans., 1823), and Minding, *Integraltafeln* (Berlin, 1849), give values of indefinite integrals and formulæ of reduction; both are useful and valuable works.

Non-numerical integrals.

De Haan, *Nouvelles Tables d'Intégrales Définies* (Leyden, 1867), is a quarto volume of 727 pages containing evaluations of definite integrals, arranged in 485 tables. The first edition appeared in vol. iv. of the *Transactions* of the Amsterdam Academy of Sciences. This, though not so full and accurate as the second edition, gives references to the original memoirs in which the different integrals are considered.

Theory of numbers.

Tables relating to the Theory of Numbers.—These are of so technical a character and so numerous that a full account cannot be attempted here. The reader is referred to Cayley's paper in the *Brit. Assoc. Rep.* for 1875, where a full description with references is given. Three tables may, however, be briefly noticed on account of their importance and because they form separate volumes: (1) Degen, *Canon Pellianus* (Copenhagen, 1817), relates to the indeterminate equation $y^2 - ax^2 = 1$ for values of a from 1 to 1000. It in fact gives the expression for $\sqrt{a}$ as a continued fraction; (2) Jacobi, *Canon Arithmeticus* (Berlin, 1839), is a quarto work containing 240 pages of tables, where we find for each prime up to 1000 the numbers corresponding to given indices and the indices corresponding to given numbers, a certain primitive root (10 is taken whenever it is a primitive root) of the prime being selected as base; (3) Reuschle, *Tafeln complexer Primzahlen, welche aus Wurzeln der Einheit gebildet sind* (Berlin, 1875), includes an enormous mass of results relating to the higher complex theories. A table of $\chi(n)$, where $\chi(n)$ denotes the sum of the complex numbers which have n for their norm for primes up to $n = 13{,}000$ (cf. *Quart. Journ.*, vol. xx. p. 152), has been published since the date of Cayley's report. Some tables that belong to the theory of numbers have been described above under "Factor Tables" (p. 7).

Bibliography.—Full bibliographical and historical information relating to tables is collected in *Brit. Assoc. Rep.* for 1873, p. 6 The principal works are: —Heilbronner, *Historia Matheseos* (Leipsic, 1742), the arithmetical portion being at the end; Scheibel, *Einleitung zur mathematischen Bücherkenntniss* (Breslau, 1771-84); Kästner, *Geschichte der Mathematik* (Göttingen, 1796–1800), vol. iii.; Murhard, *Bibliotheca Mathematica* (Leipsic, 1797–1804), vol. ii.; Rogg, *Bibliotheca Mathematica* (Tübingen, 1830), and continuation from 1830 to 1854 by Sohnke (Leipsic and London, 1854); Lalande, *Bibliographie Astronomique* (Paris, 1803), a separate index on p. 960. A great deal of accurate information upon early tables is given by Delambre, *Histoire de l'Astronomie Moderne* (Paris, 1821), vol. i.; and Nos. xix. and xx. of Hutton's *Mathematical Tracts* (1812). For a complete list of logarithmic tables of all kinds from 1614 to 1862, see De Haan, "Iets over Logarithmentafels," in *Verslagen en Mededeelingen der Koning. Akad. van Wetenschappen* (Amsterdam, 1862), pt. xiv. De Morgan's article "Tables," which appeared first in the *Penny Cyclopædia*, and afterwards with additions in the *English Cyclopædia*, gives not only a good deal of bibliographical information but also an account of tables relating to life assurance and annuities, astronomical tables, commercial tables, etc. (J. W. L. G.)

TABOO (also written TABU and TAPU) is the name given to a system of religious prohibitions which attained its fullest development in Polynesia (from Hawaii to New Zealand; see vol. xix. p. 439–40), but of which under different names traces may be discovered in most parts of the world.

Meaning.

The word "taboo" is common to the different dialects of Polynesia, and is perhaps derived from *ta*, "to mark," and *pu*, an adverb of intensity. The compound word "taboo" (tapu) would thus originally mean "marked thoroughly. Its ordinary sense is "sacred." It does not, however, imply any moral quality, but only "a connection with the gods or a separation from ordinary purposes and exclusive appropriation to persons or things considered sacred; sometimes it means devoted as by a vow." Chiefs who trace their lineage to the gods are called *arii tabu*, "chiefs sacred," and a temple is called a *wahi tabu*, "place sacred." The converse of taboo is *noa* (in Tonga *gnofoóa*), which means "general" or "common." Thus the rule which forbade women to eat with men, as well as, except on special occasions, to eat any fruits or animals offered in sacrifice to the gods, was called *ai tabu*, "eating sacred"; while the present relaxation of the rule is called *ai noa*, eating generally, or having food in common. Although it was employed for civil as well as religious purposes, the taboo was essentially a religious observance. In Hawaii it could be imposed only by priests; but elsewhere in Polynesia kings and chiefs, and even to a certain extent ordinary individuals, exercised the same power. The strictness with which the taboo was observed depended largely on the influence of the person who imposed it: if he was a great chief it would not be broken; but a powerful man often set at nought the taboo of an inferior.

General and particular taboos.

A taboo might be general or particular, permanent or temporary. A general taboo applied, *e. g.*, to a whole class of animals; a particular taboo was confined to one or more individuals of the class. Idols, temples, the persons and names of kings and of members of the royal family, the persons of chiefs and priests, and the property (canoes, houses, clothes, etc). of all these classes of persons were always taboo or sacred. By a somewhat arbitrary extension of this principle a chief could render taboo to (*i.e.*, in favor of) himself anything which took his fancy by merely calling it by the name of a part of his person. Thus, if he said "That axe is my backbone," or "is my head," the axe was his; if he roared out "That canoe! my skull shall be the baler to bale it out," the canoe was his likewise. The names of chiefs and still more of kings were taboo, and could not be uttered. If the name of a king of Tahiti was a common word or even resembled a common word, that word dropped out of use and a new name was substituted for it. Thus in course of time most of the common words in the language underwent considerable modifications or were entirely changed.

Duration.

Certain foods were permanently taboo to (*i.e.*, in favor of or for the use of) gods and men, but were forbidden to women. Thus in Hawaii the flesh of hogs, fowls, turtle, and several kinds of fish, cocoa-nuts, and nearly everything offered in sacrifice were reserved for gods and men, and could not, except in special cases, be consumed by women. In the Marquesas Islands human flesh was tabooed from women. Sometimes certain fruits, animals, and fish were taboo for months together from both men and women. In the Marquesas houses were tabooed against water: nothing was washed in them; no drop of water might be spilled in them. If an island or a district was tabooed, no canoe or person might approach it while the taboo lasted; if a path was tabooed, no one might walk on it. Seasons generally kept taboo were the approach of a great religious ceremony, the time of preparation for war, and the sickness of chiefs. The time during which they lasted varied from years to months or days. In Hawaii there was a tradition of one that lasted thirty years, during which men might not trim their beards, etc. A common period was forty days. A taboo was either common or strict. During a common taboo the men were only required to abstain from their ordinary occupations and to attend morning and evening prayers. But during a strict taboo every fire and light on the island or in the district was extinguished; no canoe was launched; no person bathed; no one, except those who had to attend at the temple, was allowed to be seen out of doors; no dog might bark, no pig grunt, no cock crow. Hence at these seasons they tied up the mouths of dogs and pigs, and put fowls under a calabash or bandaged their eyes. The taboo was imposed either by proclamation or by fixing certain marks (a pole with a bunch of bamboo leaves, a white cloth, etc.) on the places or things tabooed.

Penalty for violation.

The penalty for the violation of a taboo was either religious or civil. The religious penalty inflicted by the offended *atuas* or spirits generally took the form of a disease: the offender swelled up and died, the notion being that the *atua* or his emissary (often an infant spirit) had entered into him and devoured his vitals. Cases are on record in which persons who had unwittingly broken a taboo actually died of terror on discovering their fatal error. Chiefs and priests, however, could in the case of involuntary trangressions perform certain mystical ceremonies which prevented this penalty from taking effect. The civil penalty for breaking a taboo varied in severity. In Hawaii there were police officers appointed by the king to see that the taboo was observed, and every breach of it was punished with death, unless the offender had powerful friends in the persons of priests or chiefs. Elsewhere the punishment was milder; in Fiji (which, however, is Melanesian) death was rarely inflicted, but the delinquent was robbed and his gardens despoiled. In New Zealand this judicial robbery was reduced to a system. No sooner was it known that a man had broken a taboo than all his friends and acquaintances swarmed down on him and carried off whatever they could lay hands on. Under this system (known as *muru*) property circulated with great rapidity. If, *e.g.*, a child fell into the fire, the father was robbed of nearly all he possessed.[1]

Things naturally taboo.

Besides the permanent and the artificially created taboos there were others which arose spontaneously as a result of circumstances. Thus all persons dangerously ill were taboo and were removed from their houses to sheds in the bush; if they remained in the house and died there the house was tabooed and deserted. Mothers after childbirth were taboo, and so were their new-born children. Women before marriage were *noa*, and could have as many lovers as they chose; but after marriage they were strictly tabooed to their husbands and from every one else. One of the strictest taboos was incurred by all persons who handled the body or bones of a dead person or assisted at his funeral. In Tonga a common person who touched a dead chief was tabooed for ten lunar months; a chief who touched a dead chief was tabooed for from three to five months according to the rank of the deceased. Burial grounds were taboo; and in New Zealand a canoe which had carried a corpse was never afterwards used, but was drawn on shore and painted red. Red was the taboo color in New Zealand; in Hawaii, Tahiti, Tonga, and Samoa it was white. In the Marquesas a man who had slain an enemy was taboo for ten days: he might have no intercourse with his wife and might not meddle with fire; he had to get some one else to cook for him. A woman engaged in the preparation of cocoa-nut oil was taboo for five days or more, during which she might have no intercourse with men. A tabooed person might not eat his food with his hands, but was fed by another person; if he could get no one to feed him, he had to go down on his knees and pick up his food with his mouth, holding his hands behind him. A chief who was permanently taboo never ate in his own house but always in the open air, being fed by one of his wives; or taking his food with the help of a fern stalk so as not to touch his head with his hands; food left by him was kept for him in a sacred place; any other person eating of it was supposed to die immediately. A man of any standing could not carry provisions on his back; if he did so they became taboo and were useless to any one but himself. For the taboo was communicated as it were by infection to whatever a tabooed person or thing touched. This rule applied in its fullest force to the king and queen of Tahiti. The ground they trod on became sacred; if they entered a house, it became taboo to them and had to be abandoned to them by its owner. Hence special houses were set apart for them on their travels, and, except in their hereditary districts, they were always carried on men's shoulders to prevent them touching the ground. Elsewhere, as in New Zealand, this rule was not carried out so strictly. But even in New Zealand the spots on which great chiefs rested during a journey became taboo and were surrounded with a fence of basket-work. The head and hair, especially of a chief, were particularly taboo or sacred; to touch a man's head was a gross insult. If a chief touched his own head with his fingers he had immediately to apply them to his nose and snuff up the sanctity which they had abstracted from his head. The cutting of a chief's hair was a solemn ceremony; the severed locks were collected and buried in a sacred place or hung up on a tree. If a drop of chief's blood fell upon anything, that thing became taboo to him, *i.e.*, was his property. If he breathed on a fire, it became sacred and could not be used for cooking. In his house no fire could under any circumstances be used for cooking; no woman could enter his house before a certain service had been gone through. Whatever a new-born child touched became taboo to (*i.e.*, in favor of) the child. The law which separated tabooed persons and things from contact with food was especially strict. Hence a tabooed or sacred person ought not to leave his comb or blanket or anything which had touched his head or back (for the back was also particularly taboo) in a place where food had been cooked; and in drinking he was careful not to touch the vessel with his hands or lips (otherwise the vessel became taboo and could not be used by any one else), but to have the liquid shot down his throat from a distance by a second person.

Removal of taboo.

There were various ceremonies by which a taboo could be removed. In Tonga a person who had become taboo by touching a chief or anything belonging to him could not feed himself till he had got rid of the taboo by touching the soles of a superior chief's feet with his hands and then rinsing his hands in water, or (if water was scarce) rubbing them with the juice of the plantain or banana. But, if a man found that he had already (unknowingly) eaten with tabooed hands, he sat down before a chief, took up the foot of the latter, and pressed it against his stomach to counteract the effect of the food inside. In New Zealand a taboo could be taken off by a child or grandchild. The tabooed person touched the child and took drink or food from its hands; the man was then free, but the child was tabooed for the rest of the day. A Maori chief who became taboo by touching the sacred head of his child was disinfected, so to speak, as follows. On the following day (the ceremony could not be performed sooner) he rubbed his hands over with potato or fern root which had been cooked over a sacred fire; this food was then carried to the head of the family *in the female line*, who ate it, whereupon the hands became *noa*. The taboo was removed from a new-born child in a somewhat similar manner. The father took the child in his arms and touched its head, back, etc., with some fern root which had been roasted over a sacred fire; next morning a similar ceremony was performed on the child by its eldest relative in the female line; the child was then *noa*, *i.e.*, free from taboo. Another mode of removing the taboo was to pass a consecrated piece of wood over the right shoulder, round the loins, and back again over the left shoulder, after which the stick was broken in two and either buried, or burned, or cast into the sea.

Private taboos.

Besides the taboos already described there were others which any one could impose. In New Zealand, if a man wished to preserve his house, crop, garden, or anything else, he made it taboo; similarly he could appropriate a forest tree or a piece of drift timber, etc., by tying a mark to it or giving it a chop with his axe. In Samoa, for a similar purpose a man would set up a representation of, *e.g.*, a sea pike or shark, believing that any one who meddled with property thus protected would be killed by a sea pike or shark the next time he bathed. Somewhat similar to this was what may be called the village taboo. In the autumn the *kumera* (sweet potato) fields belonging to the village were taboo till the crop was gathered, so that no stranger could approach them; and all persons engaged in getting in the crop were taboo, and could therefore for the time engage in no other occupation. Similar taboos were laid on woods during the hunting season and on rivers during the fishing season.

Classification.

On looking over the various taboos mentioned above we are tempted to divide them into two general classes,—taboos of privilege and tabooes of disability. Thus the taboo of chiefs, priests, and temples might be described as a privilege, while the taboo imposed on the sick and on persons who had come in contact with the dead might be regarded as a disability; and we might say accordingly that the former rendered persons and things sacred or holy, while the latter rendered them unclean or accursed. But that no such distinction ought to be drawn is clear from the fact that the rules to be observed in the one case and in the other were identical. On the other hand, it is true that the opposition of sacred and accursed, clean and unclean, which plays so important a part in the later history of religion, did in fact arise by differentiation from the single root idea of taboo, which includes and reconciles them both and by reference to which alone their history and mutual relation are intelligible.

Use in sociological evolution.

The original character of the taboo must be looked for not in its civil but in its religious element. It was not the creation of a legislature but the gradual outgrowth of animistic beliefs, to which the ambition and avarice of chiefs and priests afterwards gave an artificial extension. But in serving the cause of avarice and ambition it subserved the progress of civilization, by fostering conceptions of the rights of property and the sanctity of the marriage tie,—conceptions which in time grew strong enough to stand by themselves and to fling away the crutch of superstition which in earlier days had been their sole support. For we shall scarcely err in believing that even in advanced societies the moral sentiments, in so far as they are merely sentiments and are not based on an induction from experience, derive much of their force from an original system of taboo. Thus on the taboo were grafted the golden fruits of law and morality, while the parent stem dwindled slowly into the sour crabs and empty husks of popular superstition on which the swine of modern society are still content to feed.

---

[1] The origin of this custom may perhaps be discerned in a custom of the Dieri tribe, South Australia. Among them, if a child meets with an accident, all its relations immediately get their heads broken with sticks or boomerangs till the blood flows down their faces, this surgical operation being supposed to ease the child's pain (*Native Tribes of S. Australia*, p. 280).

Diffusion of similar customs.

It remains to indicate briefly some facts which point to a wide diffusion under various names of customs similar to the taboo. As might have been expected, the taboo is found, though in a less marked form, among the Micronesians, Malays, and Dyaks, all of whom are ethnologically connected with the Polynesians. In Micronesia both the name and the institution occur: the inhabitants of certain islands are forbidden to eat certain animals and the fruits of certain trees; temples and great chiefs are tabooed from the people; any one who fishes must previously for twenty-four hours abstain from women;[1] in conversing with women men are not allowed to use certain words, etc. Again, the Malays have the custom, though apparently not the name. In Timor and the neighboring islands the word for taboo is *pamali* (or *pomali*); and during the long festival which celebrates a successful head-hunt the man who has secured the most heads is *pamali;* he must not sleep with his wife nor eat from his own hand, but is fed by women. *Pamali* is a Javanese word, and had originally in Java and Sumatra the same meaning that it now bears in Timor. In Celebes a mother after childbirth was *pamali*. Amongst the Dyaks of Borneo the *pamali* (called by the Land Dyaks *porikh*) is regularly practiced at the planting of rice, harvest home, when the cry of the gazelle is heard behind, in times of sickness, after a death, etc. At the harvest home it is observed by the whole tribe, no one being allowed to enter or leave the village. The house where a death has taken place is *pamali* for twelve days, during which no one may enter it and nothing may be taken out of it. A tabooed Dyak may not bathe, meddle with fire, follow his ordinary occupation, or leave his house. Certain families are forbidden to eat the flesh of particular animals, as cattle, goats, and snakes. The taboo is often indicated by a bundle of spears or a rattan. The Motu of New Guinea also have the taboo: a man is tabooed after handling a corpse. He then keeps apart from his wife; his food is cooked for him by his sister; and he may not touch it with his hands. After three days he bathes and is free.[2] But the Motu appear to be Malayo-Polynesians, not Melanesians proper. However, in Melanesia also we find the taboo. It flourished in Fiji. It is observed in New Caledonia in cases of death, to preserve a crop, etc. According to the Rev. R. H. Codrington, there is this distinction between the Melanesian and the Polynesian taboo, that for the former there is no supernatural sanction: the man who breaks a taboo simply pays compensation to the person on whose tabooed property he has transgressed. But Mr. R. Parkinson states that in New Britain (now New Pomerania) a person who violates a taboo-mark set on a plantation, tree, etc., is supposed to be "attacked by sickness and misfortune." To go through the similar customs observed by savages all over the world would be endless; we may, however, note that a regular system of taboo is said to exist among some of the wild tribes of the Naga Hills in India,[3] and that the rules not to touch food with the hands or the head with the hands are observed by tabooed women among one of the Fraser Lake tribes in North America.[4] In fact some of the most characteristic features of taboo—the prohibition to eat certain foods and the disabilities entailed by childbirth and by contact with the dead, together with a variety of ceremonies for removing these disabilities—have been found more or less amongst all primitive races. It is more interesting to mark the traces of such customs among civilized peoples, *e.g.*, Jews, Greeks, and Romans.

Amongst the Jews.

Amongst the Jews—(1) the vow of the Nazarite (Num. vi. 1–21) presents the closest resemblance to the Polynesian taboo. The meaning of the word Nazarite is "one separated or consecrated," and this, as we saw (p. 20), is precisely the meaning of taboo. It is the head of the Nazarite that is especially consecrated (v. 7, "his separation unto God is upon his head"; v. 9, "defile the head of his separation"; v. 11, "shall hallow his head"), and so it was in the taboo. The Nazarite might not partake of certain meats and drinks, nor shave his head, nor touch a dead body,—all rules of taboo. If a person died suddenly beside him, this was said to "defile the head of his separation," and the same effect, expressed in the same language, would apply to a tabooed Polynesian in similar circumstances. Again, the mode of terminating the vow of the Nazarite corresponds with the mode of breaking a taboo. He shaved his head at the door of the sanctuary and the priest placed food in his hands, either of which acts would have been a flagrant violation of a Polynesian taboo. (2) Some of the rules for the observance of the Sabbath are identical with rules of strict taboo; such are the prohibitions to do any work, to kindle a fire in the house, to cook food, and to go out of doors (Exod. xxxv. 2, 3; xvi. 23, 29). The Essenes strictly observed the rules to cook no food and light no fire on the Sabbath (Josephus, *Bell. Jud.*, ii. 8, 9). (3) Any one who touched a dead body was "unclean" for seven days; what he touched became unclean, and could communicate its uncleanness to any other person who touched it. At the end of seven days the unclean person washed his clothes, bathed himself, and was clean (Num. xix. 11, 14, 19, 22). In Polynesia, as we have seen, any one who touched a dead body was taboo; what he touched became taboo, and could communicate the infection to any one who touched it; and one of the ceremonies for getting rid of the taboo was washing. (4) A Jewish mother after childbirth was unclean (Lev. xii.); a Polynesian mother was taboo. (5) A great many animals were unclean, and could infect with their uncleanness whatever they touched; earthen vessels touched by certain of them were broken. Certain animals were taboo in Polynesia, and utensils which had contracted a taint of taboo were in some cases broken.

Amongst the Greeks.

Amongst the Greeks a survival, or at least a reminiscence, of a system of taboo is perhaps to be found in certain applications of the epithets "sacred" and "divine" in Homer. Thus a king or a chief is sacred (*ἱερὴ ἲς Τηλεμάχοιο*, *Od.*, ii. 409, xviii. 405, etc.; *ἱερὸν μένος Ἀλκινόοιο*, *Od.*, vii. 167, viii. 2, etc.) or divine (*διος Ὀδυσσεύς*, etc.; *Ὀδυσσῆος θείοιο*, *Il.*, ii. 335, etc.: *θείων βασιλήων*, *Od.*, iv. 691); his chariot is sacred (*Il.*, xvii. 464), and his house is divine (*Od.*, iv. 43). An army is sacred (*Od.*, xxiv. 81), and so are sentinels on duty (*Il.*, x. 56; xxiv. 681). This resembles the war-taboo of the Polynesians; on a warlike expedition all Maori warriors are taboo, and the permanent personal taboo of the chiefs is increased twofold: they are "tabooed an inch thick." The Jews also seem to have had a war-taboo, for when out on the war-path they abstain from women (1 Sam. xxi. 4, 5),—a rule strictly observed by Maori warriors on a dangerous expedition. The Dards, who with the kindred Siah Posh Kâfirs on the southern slopes of the Hindu Kush—tribes which probably of all Aryan peoples retain a social state most nearly approximating to that of the primitive Aryans—abstain from sexual intercourse during the whole of the fighting season, from May to September; and "victory to the chastest" is said to be a maxim of all the fighting tribes from the Hindu Kush to Albania.[1] The same rule of continence in war is observed by some Indian tribes of North America.[2] In Homer a fish is sacred (*Il.*, xvi. 407), and Plato points out that during a campaign the Homeric warriors never ate fish (*Rep.*, 404 B). Even in time of peace the men of Homer's day only ate fish when reduced to the verge of starvation (*Od.*, iv. 363 *sq.*; xii. 329 *sq.*). The Siah Posh Kâfirs refuse to eat fish, although their rivers abound in it.[3] The Hindus of Vedic times appear not to have eaten fish.[4] It is probable, therefore, that among the early Aryans, as among primitive peoples in various parts of the world, the eating of fish was tabooed. Again, the threshing-floor, the winnowing-fan, and meal are all sacred (*Il.*, v. 499; H. Merc., 21, 63; *Il.*, xi. 631). Similarly in New Zealand a taboo was commonly laid on places were farming operations were going on; and among the Basutos, before the corn on the threshing-floor can be touched, a religious ceremony has to be performed, and all "defiled" persons are carefully kept from seeing it.[5] Although the Homeric folk ate swine, the epithet "divine" commonly applied to a swineherd in Homer may point to a time when pigs were sacred or tabooed. In Crete pigs were certainly sacred and not eaten (Athenæus, 376a), and apparently at Pessinus also (Pausanias, vii. 17, 10). Amongst the Jews and Syrians, of course, pigs were tabooed; and it was a moot question with the Greeks whether the Jews abhorred or worshipped pigs (Plut., *Quæst. Conv.*, iv. 5). The pigs kept in the great temple at Hierapolis were neither sacrificed nor eaten; some people thought that they were sacred, others that they were unclean, ἐναγέας (Lucian, *De Dea Syria*, 54). Here we have an exact taboo, the ideas of sacredness and uncleanness being indistinguishable. Similarly by the Ojibways the dog is regarded as "unclean and yet as in some respects holy."[6] The divergence of the two conceptions is illustrated by the history of the cow among different branches of the Aryan race: the Hindus regard this animal as sacred; the Shin caste among the Dards hold it in abhorrence.[7] The general word for taboo in Greek is ἄγος, which occurs in the sense both of "sacredness" and of "pollution"; and the same is true of the adjective ἅγιος and of the rare adjective ἀναγής, "tabooed" (Bekker's *Anecdota Græca*, 212, 32; Harpocration, *s.v.* ἀναγεῖς). Usually, however, the Greeks discriminated the two senses, ἁγνός being devoted to the sense of "sacred" and ἐναγής to that of "unclean" or "accursed." "To taboo" is ἁγίζειν; "to observe a taboo" is ἁγνεύειν; and the state or season of taboo is ἁγνεία or ἁγιστεία. The rules of the Greek ἁγνεία correspond closely to those of the Polynesian taboo, consisting in "purifications, washings, and sprinklings, and in abstaining from mourning for the dead, child-bed, and all pollutions, and in refraining from certain foods," etc.[8]

Amongst the Romans.

Amongst the Romans, who preserved more traces of primitive barbarism than the Greeks, the flamen dialis was hedged in by a perfect network of taboos. He was not allowed to ride or even touch a horse, nor to look at an army under arms, nor to wear a ring which was not broken, nor to have a knot on any part of his garments; no fire, except a sacred fire, could be taken out of his house; he might not touch or even name a goat, a dog, raw meat, beans, and ivy; he might not walk under a vine; the feet of his bed had to be daubed with mud; his hair could be cut only by a freeman, and his hair and nails when cut had to be buried under a lucky tree; he might not touch a corpse, etc. His wife, the flaminica, was also subject to taboos: at certain festivals she might not comb her hair; if she heard thunder, she was taboo (*feriata*) till she had offered an expiatory sacrifice. The similarity of some of these rules to the Polynesian taboo is obvious. The Roman *feriæ* were periods of taboo; no work might be done during them except works of necessity: *e.g.*, an ox might be pulled out of a pit or a tottering roof supported. Any person who mentioned Salus, Semonia, Seia, Segetia, or Tutilina was tabooed (*ferias observabat*).[9] The Latin *sacer* is exactly "taboo"; for it means either "sacred" or "accursed."

TABRÍZ, **TAVRIS**, or **TAVRIZ**, a town of Persia, capital of the province of Aḏarbaiján (Azerbijan, ancient Atropatene), is situated in 38° 4′ N. lat. and 46° 18′ E. long., more than 4000 feet above the sea, at the eastern end of a wide valley, through which runs a river whose waters irrigate the gardens that encircle the town. In 1812 the walls had a circumference of 3½ miles. Overlooking the valley on the northeast and east are bold bare rocks, while to the south rises the more regular peak of Sahand. The town possesses few buildings of note, and of the extensive ruins but few merit attention. Mounsey in 1866 mentioned the blue mosque; the *ark* or citadel, containing the palace of the heir-apparent,—a large frowning building near the centre of the town; the Great Maidan, an open square; and the bazaars. The mosque which he ascribes to Sháh Abbas, is that of the Turcoman Jahan Sháh (1410–1468). Abbas Mirza converted the citadel into an arsenal. Among the ruins of old Tauris the sepulchre of the Mogul sultan, Ghazan Khán, is no longer to be distinguished, except as part of a huge tumulus. It is situated about 2 miles southwest from the modern town, but far within the original boundaries. The "spacious arches of stone and other vestiges of departed majesty" with which Porter found it surrounded in 1818 were possibly remains of the college (*madrasa*) and monastery (*záwíya*) where Ibn Batuta found shelter during his visit to the locality. In spite of the cholera visitation of 1822 and other occasional ravages of sickness, and the severe cold of winter, the climate of Tabríz is proverbially healthy. Its orchards and fruit gardens have a high reputation, and its running streams make amends for ill-paved and narrow streets and sorely defective municipal arrangements. General Shindler estimated the population in 1886 at about 170,000,—a number agreeing with the latest local census. The same authority states that the city contains 8 tombs of imámzádehs, 318 mosques, 100 public baths, 166 caravanserais, 3922 shops, 28 guard-houses, and 5 Christian (Armenian) churches; but this account must comprise in some of its items more buildings than are actually in use. There are said to be nearly 3000 Armenians in the place.

Tabríz is a city of extensive commerce, a great emporium for the trade of Persia on the west, and the special mart between Turkey, Russia, and Persia. It possesses an international telegraph station, and the line passes hence to Tiflis and Europe on one side and to Teheran on the other. Subsidiary lines have been constructed to near Astara on the Caspian (136 miles long) and to Saujbulak on the Kurdish frontier (125 miles long). Eastwick in 1860 estimated the value of the exports to Turkey at about £600,000 [$2,916,000] and to Russia at about £400,000 [$1,944,000], exclusive of smuggling. The chief imports were British, and some Swiss—colored cotton goods, gray calicoes, and broadcloth,—with miscellaneous goods from Germany. In 1881 there was a marked improvement in the trade of Tabríz, mainly in increased imports from Constantinople. In 1885 the imports amounted to £721,730 [$3,507,607.80] and the exports to £306,687 [$1,490,498.82]. The principal items of the former were cottons (from England), woollen cloth (from Austria and Germany), sugar (from France), and tea (from Holland); of the latter dried fruits (to Russia) and silk (to France, Austria, and Switzerland). There are lead mines near Tabríz, and cobalt and copper are obtainable from the Sahand.

There is perhaps no city in Persia on which so much has been recorded by native and foreign writers as Tabríz. Among the former Ibn Batuta, the Arab, and Hamd Ullah, the Persian, are notable. Of the latter may be mentioned Chardin, Porter, Ouseley, Tancoigne, Morier, Du Pré, Malcolm, Lady Sheil, Eastwick, Mounsey, Schindler, and Madame Dieulafoy (in *Tour du Monde*, 1883). The name *Tabríz* has been subject of much comment and conjecture, but there is no doubt that it is taken from the ancient name of Tauris. The history of Tabríz is a long and painful record of sieges and conflicts, of earthquakes and destruction by natural causes. Of late years it has recovered to some extent its former high position, and is in many respects a worthy rival to the capital.

TACITUS. The famous Roman historian Tacitus, who ranks beyond dispute in the highest place among men of letters of all ages, lived in the latter half of the first and in the early part of the 2d century of our era, through the reigns of the emperors Nero, Galba, Otho, Vitellius, Vespasian, Titus, Domitian, Nerva, Trajan. All we know of his personal history is from allusions to himself in his own works, and from eleven letters addressed to him by his very intimate friend the younger Pliny. The exact year of his birth is a matter of inference, but it may be approximately fixed near the close of the reign of Claudius, from 52 to 54 A.D. Pliny indeed speaks of Tacitus and himself as being "much of an age"[1] (*prope-modum æquales*), though himself born in 61 or 62, but he must have been some years junior to his friend, who began, he tells us,[2] his official life with a quæstorship under Vespasian in 78 or 79, at which time he must have been twenty-five years of age at least. Of his family and birthplace we know nothing certain; we can infer nothing from his name Cornelius, which was then very widely extended; but the fact of his early promotion seems to point to respectable antecedents, and it may be that his father was one Cornelius Tacitus, who had been a procurator in one of the divisions of Gaul, to whom allusion is made by the elder Pliny in his *Natural History* (vii. 76). But it is all matter of pure conjecture, as it also is whether his "prænomen" was Publius or Caius. He has come down to us simply as Cornelius Tacitus. The most interesting facts about him to us are that he was an eminent pleader at the Roman bar, that he was an eye-witness of the "reign of terror" during the last three years of Domitian, and that he was the son-in-law of the great and good Julius Agricola, the humane and enlightened governor of Britain. This honorable connection, which testifies to his high moral character, may very possibly have accelerated his promotion, which he says[3] was begun by Vespasian, augmented by Titus, and still further advanced by Domitian, under whom we find him presiding as prætor at the celebration of the secular games in 88, and a member of one of the old priestly colleges, to which good family was an almost indispensable passport. Next year, it seems, he left Rome, and was absent till 93 on some provincial business, and it is possible that in these four years he may have made the acquaintance of Germany and its peoples. His father-in-law died the year of his return to Rome. In the concluding passage of his *Life of Agricola* he tells us plainly that he witnessed the judicial murders of many of Rome's best citizens from 93 to 96, and that being himself a senator he felt almost a guilty complicity in them. "Our hands," he says, "dragged Helvidius to prison; we were steeped in Senecio's innocent blood."[4] With the emperor Nerva's accession his life became bright and prosperous, and so it continued through the reign of Nerva's successor, Trajan, he himself, in the opening passage of his *Agricola*, describing this as a "singularly blessed time" (*beatissimum seculum*); but the hideous reign of terror had stamped itself ineffaceably on his soul, and when he sat down to write his *History* he could see little but the darkest side of imperialism. To his friend the younger Pliny we are indebted for all we know (and this is but trifling) about his later life. He was advanced to the consulship in 97, in succession to a highly distinguished man, Virginius Rufus, on whom he delivered in the senate a funeral eulogy. "The good fortune of Virginius," says Pliny,[5] "was crowned by having the most eloquent of panegyrists." In 99 he was associated with Pliny in the prosecution of a great political offender, Marius Priscus, under whom the provincials of Africa had suffered grievous wrongs. The prosecution was successful, and we have Pliny's testimony[6] that Tacitus spoke with his characteristic dignity. Both received a special vote of thanks from the senate for their conduct of the case. Of his remaining years we know nothing, and we may presume that he devoted them exclusively to literary work. It would seem that he lived to the close of Trajan's reign, as he seems[7] to hint at that emperor's extension of the empire by his successful Eastern campaigns from 115 to 117. Whether he outlived Trajan is matter of conjecture. It is worth noticing that the emperor Tacitus in the 3d century claimed descent from him, and directed that ten copies of his works should be made every year and deposited in the public libraries. He also had a tomb built to his memory, which was destroyed by order of Pope Pius V. in the latter part of the 16th century. Tacitus, as we gather from one of Pliny's letters,[8] had a great reputation during his lifetime. On one occasion a Roman knight, who sat by his side in the circus at the celebration of some games, asked him, "Are you from Italy or from the provinces?" His answer was, "You know me from your reading." To which the knight replied "Are you then Tacitus or Pliny?"

Pliny, as we see clearly from several passages in his letters, had the highest opinion of his friend's ability and worth. He consults him about a school which he thinks of establishing at Comum (Como), his birthplace, and asks him to look out for suitable teachers and professors. And he pays[9] him the high compliment, "I know that your *Histories* will be immortal, and this makes me the more anxious that my name should appear in them."

The following is a list of Tacitus's remaining works, arranged in their probable chronological order, which may be approximately inferred from internal evidence:—(1) the *Dialogue on Orators*, about 76 or 77; (2) the *Life of Agricola*, 97 or 98; (3) the *Germany*, 98, published probably in 99; (4) the *Histories* (*Historiæ*), completed probably by 115 or 116, the last years of Trajan's reign (he must have been at work on them for many years); (5) the *Annals*, his latest work probably, written in part perhaps along with the *Histories*, and completed subsequently to Trajan's reign, which he may very well have outlived.

The *Dialogue on Orators* discusses, in the form of a conversation which Tacitus professes to have heard (as a young man) between some eminent men at the Roman bar, the causes of the decay of eloquence under the empire. There are some interesting remarks in it on the change for the worse that had taken place in the education of Roman lads.

The *Life of Agricola*, short as it is, has always been considered an admirable specimen of biography. The great man with all his grace and dignity is brought vividly before us, and the sketch we have of the history of our island under the Romans gives a special interest to this little work.

The *Germany*, the full title of which is "Concerning the geography, the manners and customs, and the tribes of Germany," describes with many suggestive hints the general character of the German peoples, and dwells particularly on their fierce and independent spirit, which the author evidently felt to be a standing menace to the empire. The geography is its weak point; this was no doubt gathered from vague hearsay.

The *Histories*, as originally composed in twelve books, brought the history of the empire from Galba in 69 down to the close of Domitian's reign in 97. The first four books, and a small fragment of the fifth, giving us a very minute account of the eventful year of revolution, 69, and the brief reigns of Galba, Otho, and Vitellius, are all that remain to us. In the fragment of the fifth book we have a curious and interesting account of the Jewish nation, of their character, customs, and religion, from a cultivated Roman's point of view, which we see at once was a strongly prejudiced one.

The *Annals*—a title for which there is no ancient authority, and which there is no reason for supposing Tacitus gave distinctively to the work—record the history of the emperors of the Julian line from Tiberius to Nero, comprising thus a period from 14 A.D. to 68. Of these, nine books have come down to us entire; of books v., xi., and xvi. we have but fragments, and the whole of the reign of Caius (Caligula), the first six years of Claudius, and the last three years of Nero are wanting. Out of a period of fifty-four years we thus have the history of forty years.

An attempt has been made recently to prove that the *Annals* are a forgery by Poggio Bracciolini, an Italian scholar of the 15th century, but their genuineness is confirmed by their agreement[1] in various minute details with coins and inscriptions discovered since that period. Another important fact has been brought to light. Ruodolphus, a monk of a monastery at Fulda in Hesse-Cassel, writing in the 9th century, says that Cornelius Tacitus speaks of the river known to moderns as the Weser as the Visurgis. In the *Annals* as they have come down to us we find the Visurgis mentioned five times in the first two books, whence we may conclude that a manuscript of them was in existence in the 9th century. Add to this the testimony of Jerome that Tacitus wrote in thirty books the lives of the Cæsars, and the evidence of style, and there cannot be much doubt that in the *Annals* we have a genuine work of Tacitus.

Much of the history of the period described by him, especially of the earlier Cæsars, must have been obscure and locked up with the emperor's private papers and memoranda. As we should expect, there was a vast amount of floating gossip, which an historian would have to sift and utilize as best he might. Tacitus, as a man of good social position, no doubt had access to the best information, and must have talked matters over with the most eminent men of the day. There were several writers and chroniclers, whom he occasionally cites but not very often; there were memoirs of distinguished persons,—those, for example of the younger Agrippina, of Thrasea, and Helvidius. There were several collections of letters, like those of the younger Pliny; a number, too, of funeral orations; and the "acta senatus" and the "acta populi" or "acta diurna," the first a record of proceedings in the senate, the latter a kind of gazette or journal. Thus there were the materials for history in considerable abundance, and Tacitus was certainly a man who knew how to turn them to good account. He has given us a striking, and on the whole doubtless a true, picture of the empire in the 1st century. He wrote, it may be admitted, with a political bias and a decided turn for satire, but he assuredly wrote with a high aim, and we may accept his own account of it: "I regard[2] it as history's highest function to rescue merit from oblivion, and to hold up as a terror to base words and actions the reprobation of posterity." Amid great evils he recognized the existence of truly noble virtues even in his own degenerate age. Still for the most part he writes as a man who felt deeply that the world was altogether "out of joint"; the empire was in itself in his view a huge blunder, and answerable more or less directly for all the diseases of society, for all the demoralization and corruption of the great world of Rome, though as to the provinces he admits that they were better off in many ways under the emperors than they had been in the last days of the republic. But his political sympathies were certainly with the old aristocratic and senatorian régime, with the Rome of the Scipios and the Fabii; for him the greatness of his country lay in the past, and, though he felt her to be still great, her glory was, he thought, decidedly on the wane. He was, in fact, a political idealist, and could hardly help speaking disparagingly of his own day. In his *Germany* he dwells on the contrast between barbarian freedom and simplicity on the one hand and the servility and degeneracy of Roman life on the other. Yet he had a strong and sincere patriotism, which invariably made him minimize a Roman defeat and the number of Roman slain. There seems to have been a strange tinge, too, of superstition about him, and he could not divest himself of some belief[3] in astrology and revelations of the future through omens and portents, though he held these were often misunderstood and misinterpreted by charlatans and impostors. On the whole he appears to have inclined to the philosophical theory of "necessitarianism," that every man's future is fixed from his birth; but we must not fasten on him any particular theory of the world or of the universe. Sometimes he speaks as a believer in a divine overruling Providence, and we may say confidently that with the Epicurean doctrine he had no sort of sympathy.

His style, whatever judgment may be passed on it, is certainly that of a man of genius, and cannot fail to make a deep impression on the studious reader. Tacitean brevity has become proverbial, and with this are closely allied an occasional obscurity and a rhetorical affectation which his warmest admirers must admit. He has been compared to Carlyle, and there are certainly resemblances between the two both in style and tone of thought. Both affect singularity of expression; both incline to an unhopeful and cynical view of the world. Tacitus was probably never a popular author; to be understood and appreciated he must be read again and again, or the point of some of his acutest remarks will be quite missed. He has been several times translated, but it has always been felt that he presents very great, if not insuperable, difficulties to the translator.

Murphy's translation (a paraphrase we should call it) is perhaps one of the best known; it was published early in the present century. On this was based the so-called Oxford translation, published by Bohn in a revised edition. The latest translation is that by Messrs. Church and Brodribb. There is on the whole a good French translation by Louandre. The editions of Tacitus are very numerous. Among more recent editions, the best and most useful are Orelli's (1859); Ritter's (1864); Nipperdey's (1879); Furneaux's (*Annals*, i.–vi.), vol i., Clarendon Press, 1884.

(W. J. B.)

TACITUS, M. Claudius, Roman emperor from September 25, 275, to April, 276, was a native of Interamna (Terni) in Umbria, and was born about the year 200. In the course of his long life he discharged the duties of various civil offices, including that of consul in 273, with universal respect. Six months after the assassination of Aurelian he was chosen by the senate to succeed him, and the choice was cordially ratified by the army. During his brief reign he set on foot some domestic reforms, and sought to revive the authority of the senate, but, after a victory over the Alani near the Palus Mæotis, he succumbed to the hardships and fatigues of his new duties at Tyana in Cappadocia. Tacitus, beside being a man of immense wealth (which he bequeathed to the state), had considerable literary culture, and was proud to claim descent from the historian, whose works he caused to be transcribed at the public expense and placed in the public libraries.

TACTICS. See War.

TADMOR. See Palmyra.

TAFILELT, a large oasis in Morocco (see vol. xvi. p. 856). The principal place is Abuam.

TAGANROG, a seaport of southern Russia, on the northern shore of the Sea of Azoff, in the government of Ekaterinoslaff, and nearly 200 miles southeast of its chief town. It is built, principally of wood, on a low cape, and, with its extensive storehouses, exchange, and wholesale shops, has the aspect of an important commercial city. It is well provided with educational institutions for children, and has a library and a theatre. The imperial palace, where Alexander I. died in 1825, and the Greek monastery (under the patriarch of Jerusalem) are worthy of notice. The advantageous situation of Taganrog was well known as early as the 13th century, when Pisan merchants founded there a colony, Portus Pisanus, which, however, was destined soon to disappear during the great migrations of the Mongols and Turks. An attempt to obtain possession of the promontory was made by Peter I., but it was not definitely annexed by the Russians until seventy years afterwards (1769). Its commercial importance dates from the second half of the present century; in 1870 its population had risen to 38,000, and after it had been brought into railway connection with Kharkoff and Voronezh, and thus with the fertile provinces of south and southeast Russia, the increase was still more rapid, the number reaching 63,025 in 1882,—Greeks, Jews, Armenians, and West-Europeans being important elements. Notwithstanding the disadvantages of its open roadstead, the foreign trade of Taganrog rapidly expanded, the annual value of the exports having recently reached £2,500,000 [$12,150,000]. The chief article of export being corn, the trade of the city, depending on the crops in south Russia, is subject to great fluctuations. Linseed and other oil-bearing grains are also important articles of commerce, as well as tallow and butter. The imports, which consist chiefly of fruits (dried and fresh), wine, oil, and coffee, are much smaller than the exports; and of the 989 ships (499,500 tons) that entered the port in 1885 no fewer than 775 (446,500 tons) were in ballast. The coasting trade, chiefly with Rostoff, was represented in the same year by 1321 vessels (224,000 tons) entering and 1343 vessels clearing.

The roadstead of Taganrog is very shallow, and exposed to winds which cause great variations in the height of the water; it is, moreover, rapidly silting up. At the quay the depth of water is only 8 to 9 feet, and large ships have to lie 5 to 13 miles from the town.

Taganrog, with the surrounding territory of 137,000 acres, having a population of nearly 30,000, living in a dozen villages, constitutes a separate township, and, though reckoned to the Rostoff district of Ekaterinoslaff, has a separate governor and administration.

TAGLIACOZZI, Gasparo (1546–1599), a surgeon of wide repute, was born at Bologna in 1546, and studied at that university under Cardan, taking his degree in philosophy and medicine at the age of twenty-four. He was appointed professor of surgery and afterwards of anatomy, and achieved notoriety at least, and the fame of a wonder-worker. He died at Bologna on November 7, 1599.

His principal work is entitled *De Curtorum Chirurgia per Insitionem Libri Duo* (Venice, 1597, fol.); it was reprinted in the following year under the title of *Chirurgia Nova de Narium, Aurium, Labiorumque Defectu per Insitionem Cutis ex Humero, arte hactenus omnibus ignota, sarciendo* (Frankfort, 1598, 8vo). The latter title sufficiently indicates the art which he professed of repairing nose, ears, and lips by a species of ingrafting of skin from the arm, that member being kept in apposition with the part to be repaired until such time as the semi-detached graft had formed its new vascular connections. His Latinized name of Taliacotius is well known to the readers of Butler (*Hudibras*, i. 1), whose humorous representation of the nature of the Taliacotian art is, however, in some important particulars inaccurate.

TAGLIONI, Marie (1809–1884), a ballet dancer, was the daughter of Filippo Taglioni, an Italian master of the ballet, and was born at Stockholm, 23d April, 1809. She was trained by her father, who in his discipline is said to have been pitilessly severe. It was to his care and her own special talent for dancing that she owed her success, for she possessed no remarkable personal attractions. Her first appearance was at Vienna, 10th June, 1822, in a ballet of which her father was the author, *La Réception d'une jeune nymphe à la cour de Terpsichore.* Her success was immediate, and was repeated in the chief towns of Germany. On 23d July, 1827, she made her debut at the Opera House, Paris, in the *Ballet de Sicilien*, and aroused a furore of enthusiasm. Her style was entirely new, and may be termed ideal as opposed to the realistic and voluptuous ballet previously in vogue. Among her more remarkable performances were the dancing of the Tyrolienne in *Guillaume Tell* and of the *pas de fascination* in Meyerbeer's *Robert le Diable.* At this period the ballet was a much more important feature in opera than it is now, and in fact with her retirement in 1845 the era of grand ballets may be said to have closed. In 1832 she married Comte Gilbert de Voisins, by whom she had two children. Losing her savings in speculation, she afterwards supported herself in London as a teacher of deportment, especially in connection with the ceremony of presentation at court. During the last two years of her life she stayed with her son at Marseilles, where she died in April, 1884. Taglioni is frequently mentioned in the novels of Balzac; and Thackeray, in *The Newcomes*, says that the young men of that epoch "will never see anything so graceful as Taglioni in *La Sylphide.*"

TAGUS (Span. *Tajo*, Portug. *Tejo*), the longest river of the Iberian Peninsula. Its length is 566 miles, of which 192 are on or within the frontier of Portugal, and the area of its basin, according to Strelbitsky, is 31,864 square miles. The basin is comparatively narrow, and the Tagus, like the other rivers of the Iberian tableland, generally flows in a rather confined valley, often at the bottom of a rocky gorge at a considerable depth below the general level of the adjacent country. The source of the river is at the height of 5225 feet above sea-level, on the western slope of the Muela de San Juan, in the southwest of the province of Teruel. Thence it flows at first northwestwards, but, after receiving the Rio Gallo on the right, it flows west, and then southwest or west-southwest, which is its general direction for the rest of its course. The rocky gorges which occur in its course (the principal being where the river is overhung on the right bank by the ancient city of Toledo, and again at the Puente del Arzobispo, near the frontier of Estremadura) all belong to the Spanish section of the river, and in this section the stream is frequently encumbered by sandy shallows or broken by rocky rapids, and is not navigable except for short distances. The Portuguese section has a quieter current, and Villavelha, the highest point to which boats can ascend, lies within the Portuguese frontier. Regular river-navigation begins only at Abrantes, a few miles below which the Tagus is greatly widened by receiving on its right bank the impetuous Zezere from the Serra da Estrelha. Passing Santarem, the highest point to which the tide ascends, and the limit of navigation for large sailing vessels and steamers, the river divides below Salvaterra into two arms, called the Tejo Novo (the only one practicable for ships) and the Mar de Pedro, and these arms enclose a deltaic formation, a low tract of marshy alluvium known as the Lezirias, traversed by several natural canals or minor branches of the river. Both these arms enter the upper end of the fine Bay of Lisbon (11½ miles long by about 7 broad), and the Tagus leaves this bay in the form of a channel 4½ miles long by 2 wide (see vol. xiv. p. 696), communicating with the ocean, but having unfortunately a bar at its mouth. On the north side of this channel stands the city of Lisbon. Only slight traces are still to be found of the gold for which the sands of the Tagus were anciently celebrated.

The narrower part of the Tagus basin lying to the south, the tributaries on the left bank are almost all mere brooks, most of which dry up in summer. The principal exception is the Rio Zatas or Sorraya, which, rising in the Serra d'Ossa, flows westwards across the plateau of Alemtejo, and joins the Mar de Pedro. The principal tributaries on the right bank, besides the Zezere, are the Jarama, descending from the tableland of New Castile a little below Aranjuez, the Alberche and the Tietar, which collect their head waters from opposite sides of the Sierra de Gredos, and the Alagon, from the rough and broken country between the Sierras de Gredos and Gata.

See vol. xix. Plate III.

TAHITI ARCHIPELAGO. The eastern Polynesian island-group generally known as the Society Islands (*Isles de la Société*, or *Taïti*) lies between 16° and 18° S. lat. and 148° and 155° W. long., and stretches for nearly 200 miles in a northwest and southeast direction; the total area does not exceed 650 square miles, of which 600 fall to Tahiti alone. To the east and northeast a channel of only 140 miles in breadth, but over 2000 fathoms in depth, separates this group from the great chain of the Low Islands, beyond which the ocean extends unbroken to America. To the west as far as Fiji—the main islands of which group lie between the same degrees of latitude as those of Tahiti—there are 1500 miles of open water. About 300 miles southwest lies Cook's Archipelago, and at the same distance south are the Austral Islands. To the north, excepting a few coral banks, there is open sea to Hawaii, a distance of 2600 miles.

Tahiti occupies a central position in the Pacific. Sydney lies about 3400 miles to the west and San Francisco about as far to the north-northeast. Honolulu, Noumea, and Auckland are each somewhere about 2400 miles away; Panama is at a distance of 4600 miles.

The archipelago consists of eleven islands, which are divided into two clusters—the Leeward and the Windward Islands—by a clear channel of 60 miles in breadth. The Leeward Islands, to which alone the name of Society Islands was given by Cook, are Tubai or Motu-iti, a small uninhabited lagoon island, the most northern of the whole archipelago; Maupiti or Mau-rua—"Double Mountain," the most western; Bora-bora (Bola-Bola of the older navigators), or Fáarui: Tahaa; Raiatea or Ulietea (Boenshea's Princessa), the largest island of this cluster, and Huahine, which approach each other very closely, and are encircled by one reef. To the Windward Islands, the Georgian Islands of the early missionaries, belong Maiaiti or Tapamanu (Wallis's Sir Charles Saunders Island and Boenshea's Pelada); Morea or Eimeo (Wallis's Duke of York Island and Boenshea's San Domingo); Tahiti—Cook's Otaheiti (probably Quiros's Sagittaria; Wallis's King George's Island, Bougainville's Nouvelle Cythère, and Boenshea's Isla d'Amat), the most southern and by far the largest of all the islands; Tetuara or Tetiaroa—"The Distant Sea" (? Quiros's Fugitiva; Bougainville's Umaitia and Boenshea's Tres Hermanos); and Matia or Maitea (? Quiros's La Dezana, Wallis's Osnaburg Island, Bougainville's Boudoir and Pic de la Boudeuse, and Boenshea's San Cristoval), which is by a degree the most eastern of the archipelago. Bellinghausen, Scilly, and Lord Howe (Mopia) are three insignificant clusters of coral islets to the northwest and west, and like Tubai, and Tetuara, are atolls. The length of the Tetuara reef ring is about six miles; it bears ten palm-covered islets, of which several are inhabited, and has one narrow boat-passage leading into the lagoon. With the exception just named, the islands, which agree very closely in geological structure, are mountainous, and present perhaps the most wonderful example of volcanic rocks to be found on the globe. They are formed of trachyte, dolerite, and basalt. There are raised coral beds high up the mountains, and lava occurs in a variety of forms, even in solid flows; but all active volcanic agency has so long ceased that the craters have been almost entirely obliterated by denudation. Hot springs are unknown, and earthquakes are slight and rare. Nevertheless, under some of these flows remains of plants and insects of species now living in the islands have been found,—a proof that the formation as well as the denudation of the country is, geologically speaking, recent. In profile the islands are rugged. A high mountain, usually with very steep peaks, forms the centre, if not the whole island; on all sides steep ridges descend to the sea, or, as is oftener the case, to a considerable belt of flat land. These mountains, excepting some stony crags and cliffs, are clothed with dense forest, the soil being exceptionally fertile. All voyagers agree that for varied beauty of form and color the Society Islands are unsurpassed in the Pacific. Innumerable rills, fed by the fleeting clouds which circle round the high lands, gather in lovely streams, and after heavy rains, torrents precipitate themselves in grand cascades from the mountain cliffs—a feature so striking as to have attracted the attention of all voyagers, from Wallis downwards. Round most of the islands there is a luxuriant coral growth; but, as the reefs lie at no great distance, and follow the line of the coast, the inter-island channels are safer than those of the neighboring Tuamotus, which exhibit the atoll formation in perhaps its fullest development, and in consequence have been justly called the "Low" or "Dangerous Archipelago." Maitea, which rises from the sea as an exceedingly abrupt cone, and Tapamanu appear to be the only islands which have not their fringing and more or less completely encircling barrier-reefs.[1] The coasts are fairly indented, and protected by these reefs, which often support a chain of green islets, afford many good harbors and safe anchorages. In this respect the Society Islands have the advantage of most of the Polynesian groups.

The island of Tahiti, in shape not unlike the figure 8, has a total length of 35 miles, a coast-line of 120, and a superficial area of 600 square miles. It is divided into two distinct portions by a short isthmus (Isthmus de Taravao) less than a mile in width, and nowhere more than 50 feet above sea-level. The southern, the peninsula of Tairabu, or Tahiti-iti (Little Tahiti), alone as large as Raiatea (after Tahiti the most important island of the group), measures 12 miles in length by 6 miles in breadth; while the northern, the circular main island of Porionuu, or Tahiti-uni (Great Tahiti), has a length of 23 miles and a width of 20. The whole island is mountainous. A little to the northwest of the centre of Great Tahiti the Society Islands attain their greatest altitude. There the double-peaked Orohena rises to 7340 feet, and Aorai, its rival, is only a few hundred feet lower. Little Tahiti cannot boast of such mountains, but its tower-like peaks are very striking. The flat land of the Tahitian coast, extending to a width of several miles—with its chain of villages, its fertile gardens, and its belt of palms, sometimes intersected by stream-fed valleys which open on the sea-shore—forms a most pleasing foreground to the grand amphitheatre-like mountain ranges. A good road surrounds the entire island, which is divided into eighteen districts, each under a chief and a municipal council of which he is president. A railroad is in contemplation. By the last census the population of the entire island was 9194, one-eighth being French and foreigners. The majority of the natives profess the Protestant religion.[1]

---

[1] Darwin, *Structure of Coral Reefs*, London, 1842.

The extreme north of the island is formed by Point Venus, to the east of which lies the Bay of Matavai, and some miles still farther east Papeete, the European town and the seat of government. The beautiful harbor, of fair size and depth, is entered by two passages in the reef, Papeete to the north, 7 fathoms in depth, and Taunoa to the east, the wider and more convenient, though shallower. The town, in 1881, had a population of 3224, half of whom were French or French half-castes, but at least a dozen different nations were represented by the 800 whites. The little city is decidedly French in character. "Papeete is the emporium of trade for the products of the South Sea Islands east of 160° E. long. Small schooners of from 20 to 50 tons burden bring the produce of the various groups to Tahiti, whence they are shipped direct for Europe, either by Cape Horn or the Cape of Good Hope, according to the season of the year. These schooners, of which about twenty fly the Tahitian flag, take back portions of the cargoes of vessels arriving from Europe for sale or barter amongst the islands. The chief exports are cocoa-nuts, mother-of-pearl, cotton, and some sugar, mainly to England and Germany, very little to France; and oranges, trepang (for China), and edible fungus to California."[2] Many whalers formerly visited Papeete harbor, but for some years there has been a steady diminution in their number. In 1845 forty-eight called there, in 1860 five, and none in 1874. Commerce has also in other respects decreased. Three sugar-mills with distilleries attached, two cotton manufactories, and a manufactory of cocoa-nut fibre were at work in 1886. Oranges and vanilla are profitably grown. The timber of the country is hardly used, great quantities of Californian pine being imported. Oxen and hogs are reared. The artificial culture of the pearl oyster is beginning to be discussed, but the pearls of the Society Islands are not to be compared in number or quality to those of the Tuamotus. A good deal of trading in fruit, fibre, shell, etc., is carried on with the natives, but still mainly by barter. The competition of the Chinese immigrants, of whom in 1886 there were already 400 on Tahiti and Eimeo, is beginning to be keenly felt. The importation of "labor," chiefly for the plantations, from other Polynesian islands was placed under Government control in 1862. The Tahitians themselves prefer handicrafts to agricultural work, and many are employed as artisans by European masters, who find them as handy and industrious as their own countrymen, but for domestic service they show no aptitude. Papeete is in direct sailing communication with San Francisco, and with Sydney by a Government steamer which calls every five months; also with France by Bordeaux steamers which touch on their way to Noumea.[3]

Climate.—The seasons are not well defined. Damp is excessive; there is little variation in the weather, which, though hot, is nevertheless not depressing, and the climate for the tropics must be considered remarkably healthy. The rainfall is largest between December and April, but there is so much at other times of the year also that these months hardly deserve the name of the rainy season. During this period northwest winds are frequent, continuing at times for weeks, and there are thunderstorms and hurricanes, though they are not nearly so destructive as in some of the neighboring islands. During the eight drier and cooler months southeast winds (corresponding with the trades) prevail, but there are southerly winds which bring rain, and even westerly breezes are not unfrequent. The mean temperature for the year is 77° F.; maximum 84°, minimum 69°. The average rainfall from December to March (4 months) is 29 inches; from April to November (8 months), 19 inches. The above observations apply to the coast only.

Fauna.—Neither the zoology nor the botany of the archipelago has been thoroughly investigated. Mammalians, as in other Polynesian islands, are restricted to a few species of bats (mostly of the genus *Pteropus*), rats, and mice, none of them peculiar. Of domestic animals, the pig and the dog—the former a small breed which quickly disappeared before the stronger European strains—were plentiful even in Wallis's days. The ornithology is very poor as compared with that of the Western Pacific; and, in marked contrast to the isolated Hawaiian archipelago, the Society Islands possess no peculiar genera and but few peculiar species. They claim, however, a thrush, several small parrots of great beauty, doves, pigeons, rails, and a sandpiper. Of this sandpiper, *Tringa leucoptera*, which, with many of the birds here mentioned, was discovered as far back as Cook's stay in the islands, only one specimen (now in the Leyden museum) is known to exist; and of the rest, their range being often limited to one portion of a small island, several species are (through the increase in the number of cats, etc.) threatened with extermination. A jungle-fowl (var. of *Gallus bankiva*) is found in the mountains, but as domesticated fowls were abundant, even when Tahiti was first discovered by Europeans, these wild birds are doubtless the offspring of tame birds, probably imported with the pigs and dogs by Malay vessels. There are no peculiar reptiles, and batrachians are entirely wanting. The lagoons swarm with fish of many species. Insects are poor in species, though some of them are indigenous. Crustaceans and molluscs, on the other hand, are well represented; worms, echinoderms, and corals comparatively poorly. A noteworthy feature of Tahitian conchology is the number of peculiar species belonging to the genus *Partula*, almost every valley being the habitat of a distinct form.[4]

Flora.—This, though luxuriant, is not very rich. Like the zoology, it is much poorer than that of the more western groups of the Pacific. *Metrosideros*, *Melastoma*, and *Acacia* are the only links which this typically Polynesian region has retained to join it to Australia. Four genera are peculiar, of which three are claimed by the *Compositæ* and *Lobeliaceæ*, orders characteristic of Hawaii. It is rich in trees, shrubs, and hardwood plants, poor in the smaller undergrowth. Orchids, including some beautiful species, and ferns are abundant; but, here as in Polynesia generally, *Rubiaceæ* is the order best represented. Remarkable are the banana thickets which, chiefly on Tahiti, grow at an altitude of from 3000 to 5000 feet. Along the shore—in some places almost to the extinction of all native growth—many exotics have established themselves; and a great variety of fruit-bearing and other useful trees have been successfully introduced into most of the islands.[5]

Inhabitants.—The Tahitians are a typical Polynesian race, closely connected physically with the Marquesans and Rarotongans, but widely divided from them in many of their customs. The dialects, also, of the three groups are different, the Tahitian being perhaps the softest in all Oceania. The women rank with the most beautiful of the Pacific, though the accounts given of them by early voyagers are much exaggerated; and for general symmetry of form the people are unsurpassed by any race in the world. Even now in its decadence, after generations of drunkenness and European disease and vice, grafted on inborn indolence and licentiousness, many tall and robust people (6 feet and even upwards in height) are to be found. The women, as a rule, are small in proportion to the men. Men and women of good birth can generally be distinguished by their height and fairness, and often, even in early age, by their enormous corpulence. The skin varies from a very light olive to a full dark brown. The wavy or curly hair and the expressive eyes are black, or nearly so; the mouth is large, but well-shaped and set with beautiful teeth; the nose broad (formerly flattened in infancy by artificial means); and the chin well developed. So long as the native costume was retained, the *tiputa*, an oblong piece of bark cloth with a hole in its centre for the head, and the *paru*, a plain piece of cloth round the loins, were worn alike by men and women of the higher classes. Men of all ranks wore, with or without these, the *maro*, or T bandage. The women concealed their breasts except in the company of their superiors, when etiquette demanded that inferiors of both sexes should uncover the upper part of the body. The chiefs wore short feather cloaks, not unlike those of the Hawaiians, and beautiful semicircular breastplates, dexterously interwoven with the black plumage of the frigate bird, with crimson feathers, and with sharks' teeth; also most elaborate special dresses as a sign of mourning. The priests had strange cylindrical hats, made of wicker-work and over a yard in height. Circumcision, and in both sexes tattooing, were generally practiced, and much significance was attached to some of the marks. The houses (*rare*) were long, low, and open at the sides. Household utensils were few—plain round wooden dishes, sometimes on legs, cocoa-nut shells, baskets, etc. Low stools and head-rests were used. Pottery being unknown, all food was baked in the "native oven" or roasted over the fire. Their chief musical instruments were the nose-flute (*viro*—often used as the accompaniment of song—and the drum (*pahu*). Of the latter, those kept in the *marai* were huge elaborately carved hollow cylinders of wood, the upper end of which was covered with sharks' skin. Conch-shells (*bu*) were also used. Tahitian stone adzes, which are greatly inferior in finish to those of the Hervey Islands, are, like the adzes of eastern Polynesia in general, distinguished from those of western Polynesia by their triangular section and adaptation to a socket. Slings were perhaps the favorite weapons of the Tahitians; they had also plain spears expanding into a wide blade, and clubs. The bow and arrow seem only to have been used in certain ceremonial games (*tea*). Their canoes (*vaa*), from 20 to 70 feet in length, were double or single, and provided with sail and outriggers. They were not well finished, but the high curved sterns, rising sometimes to a height of 20 feet, of those destined to carry the images of their gods, were carved with strange figures and hung with feathers.[1] Cannibalism is unknown in the Society Islands, though some ceremonies which were performed in connection with human sacrifices may possibly be survivals of this practice. The staple food of the islanders consisted of the bread-fruit, the taro-root, the yam, the sweet potato, and in some districts the wild plantain (*fei*); but they also ate much fish (the turtle was considered sacred food), as well as pigs and dogs, though of the latter, as pets, the women were so fond as to suckle the puppies sometimes even to the exclusion of their own children. *Popoi* was a favorite dish made of bananas and cocoa-nut. Kava (*ava*), which was prepared in the usual Polynesian manner, was drunk, but in moderate quantities and only by the chiefs.

---

[1] The best chart of Tahiti is that published by the French Government in 1876, and corrected down to 1881. Morea is given on the same sheet.

Tahitians were good fishermen and bold seamen. They steered by the stars, of which they distinguished many constellations. The land was carefully tended and the fields well irrigated. Three great classes were recognized: (1) the *huiari*, of divine origin, which included only the suzerain (*arirai*), who bore a semi-sacred as well as a political character, and the reigning chiefs of districts; (2) the *bue-raatira*, proprietors and cultivators of inherited land, who also built canoes, made arms, etc.; to these two classes also belonged the priests (*tahora*), who were medicine-men as well; (3) the *manahune*, fishers, artisans, etc., and slaves (*titi*). As wars and infanticide depopulated the island this class gradually acquired land and with it certain privileges. Rank is hereditary and determined by primogeniture, not necessarily in the male line. The first-born of an arirai received at birth the title of *otu;* the father, who was the first to pay homage to his own child, then abdicated, and henceforth took up the position of regent. It is easy to see that, while this custom tended to keep honors within a family, it may have encouraged the practice of infanticide, which was common in all grades of society when Tahiti was first visited by Europeans. The age at which the otu's authority became real varied according to his own abilities and the will of his subjects. Though arbitrary, the power of the arirai was limited by the power of his vassals, the district chiefs (*raatiras*), who ruled absolutely over their respective districts, and who might be of as good blood as the arirai himself. The arirai had a councillor, but was alone responsible for any act. The bi-insular form of Tahiti promoted the independence of the chiefs, and war was rarely declared or an army or fleet despatched without the raatiras being first summoned to council. Without their favor nothing could be accomplished, for their power over their own people was absolute. The form of government was thus strictly feudal in character, but it gradually centralized into a monarchy, which, in the person of Pomare II., the English missionaries greatly helped to regulate and strengthen. The arirai sent his commands by a messenger (*vea*) whose credentials were a tuft of cocoa-nut film. This tuft was returned intact as a sign of assent or torn in token of refusal. After the chief the wife ranked first, and then his brother. The arirai was carried on the shoulders of his subjects, and chiefs were not allowed to feed themselves. Women always ate apart. Their places of worship (*marai*)—national, local, or private—were square tree-surrounded enclosures. They each had a single entrance, and contained several small courts, within which were houses for the images and attendant priests. A pyramidal stone structure, on which were the actual altars, stood at the further end of the square. The marais were also used as places of sepulture of chiefs, whose embalmed bodies, after being exposed for a time, where buried in a crouching position. Their skulls, however, were kept in the houses of their nearest relations. In the great marai at Atahura the stone structure was 270 feet long, 94 feet wide, and 50 feet high, and its summit was reached by a flight of steps, built of hewn coral and basalt. Sacrificial offerings, including human sacrifices, formed a prominent part of Tahitian worship. An eye of the victim was offered to the arirai, and placed within his mouth by the officiating priest. Every household possessed its own guardian spirits (*tii*), but there were several superior divinities, of which, at the beginning of this century, Oro was the most venerated. The images, which are less remarkable than those of Hawaii, were rough representations of the human form carved in wood. Some were covered from head to foot with small human figures cut in relief; others were mere sticks clothed with feathers. The *areoi*, a licentious association of strolling players, men and women, which numbered among its ranks the highest chiefs, and practiced infanticide, was a special feature of Tahitian society.

The Tahitians are light-hearted, frivolous, courteous, and generous; but with these traits are blended deceit, irritability, and cruelty, which formerly reached an unexampled degree of savage brutality. Their notions of morality were never, according to our ideas, very precise; and their customs, such as the *tayo*, or exchange of name with the rights which it carried over the wife of the giver of the name and all her female relations, seemed to the earlier European observer strangely revolting. It would appear, however, that with the introduction of the vices of civilization such limitations as their primitive morality recognized have disappeared and all self-respect has been lost. Especially characteristic were the elaborate costume-dances (*heivas*) performed by women. Besides dancing, the singing of songs (*pehe*), and the recitation of historical and mythical ballads (*ubus*), the natives had also a variety of sports and games. During the periodical seasons of rejoicing wrestling (*maona*), boxing (*moto*), and spear-throwing (*vero patia*) matches, with foot and canoe-races, were held; also sham fights and naval reviews. They had several games in which a ball was used,—one, *apai*, not unlike our bandy, while another, *tuiraa* (played chiefly by women), was a kind of football; but surf-swimming (*faahee*) was perhaps the most favorite sport with both sexes. Kites were known. Cock-fighting (*faatitoraamoa*) was much practiced.

Discovery and Exploration.—There is little doubt that the main island and some other members of the group were visited by the Spaniard Pedro Fernandez de Quiros in February, 1607. They were rediscovered in June, 1767, by Wallis in the "Dolphin," who took nominal possession of Tahiti for George III. and named it after him. In the following year Bougainville visited Tahiti, claimed it as French, and called it La Nouvelle Cythère. With Tetuara (called by him Umaitia) and Eimeo it makes up the Archipel de Bourbon of his most inaccurate chart. Almost all we know of the early state of the islands is, however, due to Captain Cook's visits in 1769, 1773, 1774, and 1777. The name of Society Islands was given to the Leeward group on his first voyage in honor of the Royal Society. In 1774 Tahiti was also visited by two Spanish vessels, which left two priests, who remained for ten months on the island. The Spaniards named it Isla d'Amat. The islands were again visited in 1788 by the "Lady Penrhyn." Bligh in the "Bounty" spent five months on the island in the same year, and it was revisited by that ship after the famous mutiny. At this time the leading chief was Pomare, whose family had been pre-eminent in the island for more than a century. Aided by sixteen of the "Bounty" mutineers, and armed with guns procured from Bligh and a Swedish vessel, Pomare greatly strengthened his power and brought to a successful close a long struggle with Eimeo. In 1791 the "Pandora" carried off fourteen of the "Bounty" mutineers, and from this time forward visits were frequent.

Missions.—The attempt of the Spaniards in 1774 was followed by the settlement of twenty-five persons brought in 1797 by the missionary ship "Duff." Though befriended by Pomare I. (who lived till 1805), they had many difficulties, especially from the constant wars, and at length they fled with Pomare II. to Eimeo and ultimately to New South Wales, returning in 1812 when Pomare renounced heathenism. In 1815 he regained his power in Tahiti. For a time the missionaries made good progress,—a printing press was established (1817), and coffee, cotton, and sugar were planted (1819); but soon there came a serious relapse into heathen practices and immorality. Pomare II. died of drink in 1824. His successor Pomare III. died in 1827, and was succeeded by his half-sister Aimata, the unfortunate "Queen Pomare." In 1828 a new fanatical sect, the "Mamaia," arose, which gave much trouble to the missions and whose influence is still felt. The leader proclaimed that he was Jesus Christ, and promised to his followers a sensual paradise.

---

[1] The museum of the London Missionary Society and the British Museum contain important collections of Tahitian images, dresses, weapons, etc.

French Annexation.—In 1836 the French Catholic missionaries in Mangareva attempted to open a mission in Tahiti. Queen Pomare, advised by the English missionary and consul Pritchard, refused her consent, and removed by force two priests who had landed surreptitiously and to whom many of the opposition party in the state had rallied. In 1838 a French frigate appeared, under the command of M. Du Petit-Thouars, and extorted from Pomare the right of settlement for Frenchmen of every profession. Other acts of interference followed, and at length, in 1842, Admiral du Petit-Thouars procured the signature of a document placing the islands under French protection, the authority of the queen and chiefs being expressly reserved. In 1843 Petit-Thouars reappeared, and, alleging that the treaty of 1842 had not been duly carried out, deposed the queen and took possession of the islands. His high-handed action was not countenanced by the French Government, but, while it professed not to sanction the annexation, it did not retrace the steps taken. Two years were spent in reducing the party in the islands opposed to French rule; an attempt to conquer the western islands failed; and at length, by agreement with England, France promised to return to the plan of a protectorate and leave the western islands to their rightful owners. The London missionaries were replaced by French Protestants, but neither they nor the priests have been very successful, possibly because French is a compulsory subject in the Government schools. In 1880 Tahiti, including Eimeo, was proclaimed a French colony. It is the residence of the governor-general of the French dependencies in the Pacific.

Literature.—The following list includes the books which seem most to deserve mention: Hawkesworth's *Voyages*, especially Wallis's Voyage, H.M.S. "Dolphin," in vol. i., London, 1773; Cook's *Three Voyages*, with Forster's account of the second voyage; Freycinet, *Voyage de la Coquille*, and Lesson's account of the same voyage, Paris, 1839; Bennett, *Whaling Voyage*, London, 1840. For manners and customs of the natives, see Cook, Duff, Ellis. For modern statistics, see Desgraz, *La Tahiti*, Paris, 1845; *Notices Coloniales*, Paris, 1886, vol. ii. For the early history of the islands, see Ellis, *Polynesian Researches*, London, 1829; Vincendon-Dumoulin and Desgraz, *Îles Taïti*, Paris, 1844. For mission history, see *Voyage of the Duff*, London, 1799; Ellis; Williams, *Missionary Enterprise in the South Sea Islands*, London, 1839. For the French occupation, see Moerenhout, *Voyage aux Îles du Grand Océan*, Paris, 1837; Vincendon-Dumoulin and Desgraz; Pritchard, *Polynesian Reminiscences*, London, 1866. (A. V. H.)

TAIWAN. See FORMOSA.

TAJAK, TAJIK, or TAUSIK, a term originally occurring in the Pahlavi writings, and explained to mean, first, the Arabs in general, then their descendants born in Persia and elsewhere out of Arabia, and, lastly, the Persians in general and their descendants born in Turkestán and elsewhere out of Persia. Tajak has thus come to be the collective name of all communities of Iranian stock and Persian speech, wherever found in Central Asia. These are co-extensive with the former eastward and northward limits of the Persian empire; but, since the ascendency of the Tûrki races, they have become the subject element in Turkestán, Afghánistán, Bokhára, Khíva, Kashgaria, while still politically dominant in Badakhshán, Wakhán, Darwáz, Kost, and Karatéghin. In most of these places the Tajaks, with the kindred Galchas, seem to form the bulk of the population, the distinction being that *Tajak* is applied rather to the settled and more civilized lowlanders of modern Persian speech, *Galcha* to the ruder highlanders of Ferghána, Kohistán, Wakhán, etc., who speak either archaic forms of Persian or dialects intermediate between the Iranian and Sanskritic (Indian) branches of the Aryan linguistic family. The Tajaks are thus a settled Iranian people, agriculturists in the country, traders and artisans in the towns, and are essentially "Parsiván," that is, men of Persian speech—this term, however, being more specially applied to those of Afghánistán. But, although mainly of Iranian stock, with light complexion and regular features, the Tajaks claim Arab descent, regarding the district about Baghdád as their primeval home, and considering themselves the descendants of the Arabs who overran Central Asia in the first century of the Flight. At the same time, "it is evident that the inhabitants of the greater part of this region (Central Asia) must from an early period have come in contact with the successive waves of Turkish (Tûrki) and even Mongol population which broke over them; accordingly we find that, although the type is essentially Iranian, it has undergone a certain modification, . . . face, though obviously Persian, is more oblong than that of the Turk, more or less heavy cheeks, thick nose, large mouth, wide forehead. . . . middle height, powerful frame, and broad shoulders, . . . dark hair, but among the Galchas a few fair people are found" (Capt. J. M. Trotter, *Bokhára*, p. 169). The term Tajak must also be distinguished from *Sarte*, the latter simply meaning "trader" or "shopkeeper," and being applied indiscriminately to the settled as opposed to the nomad element, and especially to the urban populations, of whatever race, in Central Asia.[1] The Tajaks are known as Tâts on the west side of the Caspian (Baku, Lenkoran, etc.).

TAKA. See NUBIA.

TALAVERA DE LA REINA, a town of Spain, in the province of Toledo, is situated on the right bank of the Tagus, and on the railway from Madrid to Caceres, some 40 miles below Toledo and 64 miles southeast from Madrid. It was formerly surrounded by a triple circumvallation, portions of which still remain. It has no buildings of special interest, and its commerce and manufactures are inconsiderable. The population within the municipal limits in 1877 was 10,029.

Talavera is the birthplace (1536) of Mariana the historian. Wellington overcame a superior French force here on July 27–28, 1809.

TALBOT, FAMILY OF. Apart from its achievements, this is one of the few families in the English aristocracy which traces alike its descent and its surname from the Norman conquerors of England; and it may really be said that there has hardly been a time during the last eight hundred years in which the Talbots have not been of considerable account in public life. Yet in some periods they appear rather as a potential influence, while at certain marked epochs they stand out among the most prominent actors in English history. The name of Richard Talbot occurs in Domesday Book as the holder of nine hides of land in Bedfordshire under Walter Giffard, earl of Buckingham. There is no evidence that he came over to England with the Conqueror himself; and, as he did not hold of the king *in capite*, it is clear that he was not a leader. His son Geoffrey Talbot took part with the empress Maud against King Stephen. But apparently it was another son Hugh who continued the line; of whom it is recorded that he held the castle of Plessi against Henry I. for Hugh de Gournay, and afterwards became a monk at Beaubec in Normandy. His son Richard obtained from Henry II. the lordship of Linton in Herefordshire, and from Richard I. the custody of Ludlow castle; and his descendants for some generations appear to have been wardens of various castles on the borders of Wales. Under Edward II. a Gilbert Talbot was head of the house, and invaded Scotland in the king's company, but afterwards took part with Thomas of Lancaster against the king. He, however, was pardoned, and obtained from Edward III. a confirmation of the grant of the manor of Linton and other lands to himself and his heirs.

His son Richard, who had married a daughter of John Comyn of Badenoch, laid claim to certain lands in Scotland in her right, and, when restrained from entering that country by land (Edward III. having then made an alliance with King David), he joined in a successful expedition which invaded it by sea in the interests of Edward Baliol. Three years later he was taken prisoner in Scotland, and redeemed for 2000 marks,[1] after which the king made him governor of Berwick. He took part also in Edward's wars against France, as did likewise his son Gilbert, who succeeded him. At this time the family possessed lands in the counties of Oxford, Gloucester, Hereford, and Kent, and a little later in Berkshire, Wilts, Salop, and Essex. Another Gilbert Talbot, grandson of the last, claimed to carry the great spurs at the coronation of Henry V., and had a commission to receive the submission of Owen Glendower and his adherents. He also distinguished himself in the invasion of Normandy. He was twice married, his second wife being a Portuguese lady, but he left no male issue, and was succeeded by his brother John, the special hero of the family.

---

[1] "Quand un Usbeg est devenu complètement sédentaire . . . il devient *Sarte*; le mot *Sarte* n'est donc pas une appellation ethnique" (Charles de Ujfalvy in *Bul. Soc. Géogr.*, June, 1878). But the Tajaks, being always settled, were the first to be known as Sartes; whence the still prevalent erroneous impression that the word had a racial meaning, implying an Iranian as opposed to a Tûrki element. Nevertheless there is a certain local etiquette observed in the use of the two words *Tajak* and *Sarte*, embodied in the popular saying: "When a stranger presents himself and eats your bread, call him a *Tajak*; when he is gone you may call him a *Sarte*."

Hitherto the head of the house had borne the name of Lord Talbot; but this John, after obtaining by marriage the title of Lord Furnivall, was for his distinguished actions created earl of Shrewsbury. He made his name so terrible in France that for several generations afterwards French mothers used to threaten refractory children that the Talbots would come if they were not quiet (Brown's *Venetian Calendar*, ii. 75). He rescued Maine from the French and took Pontoise; but his own capture by the Maid of Orleans was what probably discouraged the English most of all in their disasters beyond sea. He was exchanged for an eminent French prisoner and a heavy ransom besides. He served also several times as lieutenant of Ireland, and in 1446 was created earl of Wexford and of Waterford, in addition to the title of Shrewsbury, which had been conferred upon him in 1442. He died in 1453, in an unsuccessful expedition for the recovery of Guienne, which had lately submitted to the French. His son John, Viscount Lisle, was slain along with him in the same fatal battle.

But, besides his martial exploits which live in history, this John claims some attention for his family alliances. His first wife Maud, a granddaughter of Thomas, Lord Furnivall, brought him the castle of Sheffield as part of her inheritance, and he was accordingly summoned to parliament in the days of Henry IV. as John Talbot of Hallamshire, otherwise Lord Furnivall, more than thirty years before he was made earl of Shrewsbury. The property remained in the hands of his descendants, and became a favorite residence of the family during the whole of the Tudor era; and, but for the death in 1616 of Gilbert, seventh earl of Shrewsbury, without male issue, it has been remarked by Hunter that Sheffield might have remained much longer a centre of feudal magnificence rather than of commerce and manufactures. The second wife of John, earl of Shrewsbury, was Margaret, the eldest of three daughters of Richard Beauchamp, earl of Warwick, by *his* second wife, a daughter of Thomas, Lord Berkeley. By her he obtained a third part of the Berkeley property; and, though she did not become the mother of a line of earls, her eldest son, John Talbot, was created Viscount Lisle, and it was he who fell along with his father at the disastrous battle of Chatillon in Gascony. His son Thomas, who inherited the title of Viscount Lisle, was also slain at the early age of twenty-two in a feudal contest with Lord Berkeley, arising out of a dispute as to the possession of Berkeley castle, at Nibley Green, near Wotton-under-Edge, March 20, 1470; and the title was afterwards conferred on Edward Grey, the husband of one of his two sisters.

John, the second earl of Shrewsbury, was the first earl's son by his first wife. He had been knighted at Leicester in 1426 along with the infant king Henry VI., had served in the wars of France, and been made chancellor of Ireland during his father's lifetime, when he was only Lord Talbot. Afterwards he was made lord high treasurer of England, and in 1459 was rewarded for his services to the house of Lancaster with a grant of 100 marks [$324 English] a year out of the lordship of Wakefield, forfeited by Richard, duke of York. But next year he and his brother Christopher were slain at the battle of Northampton, fighting in the cause of Henry VI. His son John succeeded him, and then his grandson George, who fought for Henry VII. at Stoke, and whom King Henry VIII. sent as his lieutenant against the rebels in that most formidable insurrection, the Pilgrimage of Grace. But perhaps the thing which most redounds to his credit is the humanity with which (as related by Cavendish) he received the fallen Cardinal Wolsey into his house at Sheffield when he was on his way up to London as a state prisoner, and endeavored to remove those gloomy anticipations of his fate which in fact brought on his last illness.

Francis, the fifth earl, took a leading part in the invasions of Scotland under Henry VIII. and Edward VI., and was one of the two peers who alone opposed the bill for abolishing the pope's jurisdiction under Elizabeth. His son George, who succeeded, was the earl to whom the custody of Mary Stuart was committed, his delicate and onerous task being rendered all the more difficult for him by the intrigues of his bold, ambitious second wife, Bess of Hardwick, the builder of Chatsworth, who had married three husbands before her union with him. Two sons of this last earl succeeded one another, and the title then devolved, for want of male issue, on the lineal descendants of Sir Gilbert Talbot of Grafton in Worcestershire, third son of John, the second earl. This Sir Gilbert had fought for Henry VII. at Bosworth, where he was severely wounded, was knighted on the field, and was throughout one of the first Tudor's most trusted councillors. He fought also at Stoke against the insurgents with Lambert Simnel, was made a knight banneret, governor of Calais, and lord chamberlain.

The ninth earl, George, descended from this Gilbert, is not distinguished by any prominent actions. He died unmarried, and his brother, who followed next, was succeeded by his grandson Francis, chiefly memorable for his unhappy fate. His second wife, a daughter of the earl of Cardigan, was seduced by the duke of Buckingham, whom the outraged husband challenged to a duel. The countess, it is said, was present at the scene, and held Buckingham's horse in the disguise of a page, saw her husband killed, and then clasped her lover in her arms, receiving bloodstains upon her dress from the embrace. Charles, the twelfth earl, son of this unfortunate nobleman, was raised by William III. to the dignity of a duke for his important diplomatic services. His position in those slippery times was altogether exceptional. Abandoning the religion of his ancestors he became a Protestant, was one of the seven who signed the invitation to William of Orange to come over, and was continually consulted by him on state affairs after he became king. Yet, being apparently of a very sensitive disposition, he seems to have at times repented what he had done, and even corresponded with James at St. Germain; yet again, in times of danger, he was as ready as ever to stake his life and fortunes in the service of his country to preserve the new settlement. It was apparently his extreme sensitiveness that caused him to be spoken of as "the king of hearts." In 1694 he was created marquis of Alton and duke of Shrewsbury, but as he left no son these titles died along with him, and the earldom of Shrewsbury devolved on his cousin Gilbert, a Roman Catholic priest.

From this time the direct line of Sir Gilbert Talbot of Grafton began to fail. A nephew three times succeeded to an uncle, and then the title devolved upon a cousin, who died unmarried in 1856. On the death of this cousin the descent of the title was for a short time in dispute, and the lands were claimed for the infant son of the duke of Norfolk under the will of the last earl; but the courts decided that, under a private Act obtained by the duke of Shrewsbury in the sixth year of George I., the title and estates must go together, and the true successor to the earldom was found in Earl Talbot, the head of another line of the descendants of Sir Gilbert Talbot of Grafton, sprung from a second marriage of Sir Gilbert's son, Sir John Talbot of Albrighton. The head of this family in the beginning of the last century was a divine of some mark, who died bishop of Durham in 1730. His son Charles, who filled the office of lord chancellor, was created Baron Talbot of Hensol in Glamorganshire in 1733: and his son again was advanced to the dignity of Earl Talbot in 1761, to which was added that of Baron Dynevor in 1780. Then succeeded a nephew who was also created Viscount Ingestre, and assumed by royal licence the surname of Chetwynd before Talbot, from his mother. (J. GA.)

---

[1] [$540, estimated for Scotch or 12 times as much for English coin.—AM. ED.]

The earl Talbot who successfully claimed the Shrewsbury title (as the eighteenth earl) was the present earl's grandfather, and all the titles just mentioned have been united in his line ever since.

TALBOT, WILLIAM HENRY FOX (1800–1877), a discoverer in photography, was the only child of William Davenport Talbot, of Laycock Abbey, Wilts, and of Lady Elizabeth Fox Strangways, daughter of the second earl of Ilchester. He was born in February, 1800, and educated at Harrow and at Trinity College, Cambridge, where he gained the Porson prize in 1820, and graduated as twelfth wrangler in 1821. From 1822 to 1872 he frequently communicated papers to the Royal Society, many of them on mathematical subjects. At an early period he had begun his optical researches, which were to have such important results in connection with photography. To the *Edinburgh Journal of Science* in 1826 he contributed a paper on "Some Experiments on Colored Flame;" to the *Quarterly Journal of Science* in 1827 a paper on "Monochromatic Light;" and to the *Philosophical Magazine* a number of papers on chemical subjects, including one on "Chemical Changes of Color." Before Daguerre exhibited in 1839 pictures taken by the sun, Talbot had obtained similar success, and as soon as Daguerre's discoveries were whispered, communicated the results of his experiments to the Royal Society (see PHOTOGRAPHY, vol. xviii. p. 837). In 1841 he made known his discovery of the calotype process, but after the discovery of the collodion process by Scott Archer, with whom he had a lawsuit in reference to his patent rights, he relinquished this field of inquiry. For his discoveries, the narrative of which is detailed in his *Pencil of Nature* (1844), he received in 1842 the medal of the Royal Society. While engaged in his scientific researches he devoted a considerable portion of his time to archæology, and this field of inquiry latterly occupied his chief attention. Besides reading papers on these subjects before the Royal Society of Literature and the Society of Biblical Archæology, he published *Hermes, or Classical and Antiquarian Researches* (1838–39), and *Illustrations of the Antiquity of the Book of Genesis* (1839). With Sir Henry Rawlinson and Dr. Hincks he shares the honor of having been one of the first decipherers of the cuneiform inscriptions of Nineveh. He was also the author of *English Etymologies* (1846). He died at Laycock Abbey, 17th September, 1877.

TALC. See GEOLOGY, vol. x. p. 203, and MINERALOGY, vol. xvi. p. 432.

TALCA, a town of Chili, capital of the province of Talca, is situated on the Claro, a tributary of the Maule, nearly due south of Santiago, with which it is connected by rail. The town has a lyceum and some woollen manufactures (especially of "ponchos"). In 1875 the population numbered 17,496, and in 1885 about 19,000.

TALENT. See NUMISMATICS, vol. xvii. p. 646–47.

TALES are, in the usual acceptance of the word, fictitious narratives, long or short, ancient or modern. In this article "tale" is used in a stricter sense, as equivalent to the German "Volks-märchen" or the French "conte populaire." Thus understood, popular tales mean the stories handed down by oral tradition from an unknown antiquity, among savage and civilized peoples. So understood, popular tales are a subject in mythology, and indeed in the general study of the development of man, of which the full interest and importance is scarcely yet recognized. Popular tales won their way into literature, it is true, at a very distant period. The Homeric epics, especially the *Odyssey*, contain adventures which are manifestly parts of the general human stock of popular narrative. Other examples are found in the *Rigveda*, and in the myths which were handled by the Greek dramatists. Collections of popular tales, more or less subjected to conscious literary treatment, are found in Sanskrit, as in the work of Somadeva, whose *Kathá Sarit Ságara*, or "Ocean of the Streams of Story," has been translated by Mr. Tawney (Calcutta, 1880). The THOUSAND AND ONE NIGHTS (*q.v.*) are full of popular tales, and popular tales are the staple of the mediæval *Gesta Romanorum*, and of the collections of Straparola and other Italian conteurs. In all these and similar gatherings the story, long circulated from mouth to mouth among the people, is handled with conscious art, and little but the general outline of plot and character of incident can be regarded as original. In the *Histoires ou Contes du Temps Passé* of Perrault (Elzevir, Amsterdam, 1697; the Parisian edition is of the same date) we have one of the earliest gatherings of tales which were taken down in their nursery shape as they were told by nurses to children. This at least seems probable, though M. Alfred Maury thinks Perrault drew from literary sources. Perrault attributed the composition to his son, P. Darmaucour, at that time a child, and this pretext enabled him to give his stories in a simple and almost popular guise. In the dedication signed by the boy, Perrault offers remarks which really do throw a certain light on the origin and characteristics of "märchen." He says, "Ils renferment tous une morale très sensée . . . . et donnent une image de ce qui se passe dans les moindres familles, où la louable impatience d'instruire les enfans fait imaginer des histoires dépourvûes de raison pour s'accomoder à ces mêmes enfants, qui n'en ont pas encore." It seems that popular tales in many cases probably owe their origin to the desire of enforcing a moral or practical lesson. It appears that their irrational and "infantile" character—"dépourvûes de raison"—is derived from their origin, if not actually among children, at least among childlike peoples, who have not arrived at "raison," that is, at the scientific and modern conception of the world and of the nature of man.

The success of Perrault's popular tales brought the genre into literary fashion, and the Comtesse d'Aulnoy invented, or in some cases adapted, "contes," which still retain a great popularity. But the precise and scientific collection of tales from the lips of the people is not much earlier than our century. The chief impulse to the study was given by the brothers Grimm. The first edition of their *Kinder- und Haus-Märchen* was published in 1812. The English reader will find a very considerable bibliography of popular tales, as known to the Grimms, in Mrs. Alfred Hunt's translation, *Grimm's Household Tales, with Notes* (London, 1884). "How unique was our collection when it first appeared," they exclaim, and now merely to enumerate the books of such traditions would occupy much space. In addition to the märchen of Indo-European peoples, the Grimms became acquainted with some Malay stories, some narratives of Bechuanas, Negroes, American Indians, and Finnish, Esthonian, and Magyar stories. Thus the Grimms' knowledge of non-European märchen was extremely slight. It enabled them, however, to observe the increase of refinement "in proportion as gentler and more humane manners develop themselves," the monstrosities of Finnish and Red-Indian fancy gradually fading in the narratives of Germans and Italians. The Grimms notice that the evolution of popular narrative resembles the evolution of the art of sculpture, from the South-Sea idol to the frieze of the Parthenon, "from the strongly marked, thin, even ugly, but highly expressive forms of its earliest stages to those which possess external beauty of mould." Since the Grimms' time our knowledge of the popular tales of non-European races has been greatly enriched. We possess numbers of North-American, Brazilian, Zulu, Swahili, Eskimo, Samoan, Maori, Kaffir, Malagasy, Bushman, and even Australian märchen, and can study them in comparison with the stories of Hesse, of the West Highlands of Scotland, of Scandinavia.

While the popular romances of races of all colors must be examined together, another element in this subject is not less important. It had probably been often observed before, but the fact was brought out most vividly by Von Hahn (*Griechische und albanesische Märchen*, Leipsic, 1864), that the popular tales of European races turn on the same incidents, and display the same succession of situations, the same characters, and the same plots, as are familiar in the ancient epic literature of Greece, India, Germany, and Scandinavia. The epics are either fully-developed märchen evolved by the literary genius of poets and saga-men, or the märchen are degenerate and broken-down memories of the epics and sagas, or perhaps there may be examples of both processes. The second view,—namely, that the popular tales are, so to speak, the scattered grains of gold of which the epic is the original "pocket" or "placer,"—the belief that the märchen are the detritus of the saga,—was for a long time prevalent. But a variety of arguments enforce the opposite conclusion, namely, that the märchen are essentially earlier in character than the epic, which is the final form to which they have been wrought by the genius of Homer or of some other remote yet cultivated poet. If this view be accepted, the evolution of märchen and of certain myths has passed through the following stages:

(1) The popular tale, as current among the uncultivated people, such as Iroquois, Zulus, Bushmen, Samoans, Eskimo, and Samoyedes. This tale will reflect the mental condition of rude peoples, and will be full of monstrous and miraculous events, with an absence of reason proper, as Perrault says, "a ceux qui n'en ont pas encore." At the same time the tale will very probably enforce some moral or practical lesson, and may even appear to have been invented with this very purpose, for man is everywhere impressed with the importance of *conduct*.

(2) The same tale—or rather a series of incidents and a plot essentially the same—as it is discovered surviving in the oral traditions of the illiterate peasantry of European races. Among them the monstrous element, the ferocity of manners observed in the first stage, will be somewhat modified, but will be found most notable among the Slavonic tribes. Nowhere, even in German and Scottish märchen, is it extinct, cannibalism and cruel torture being favorite incidents.

(3) The same plot and incidents as they exist in the heroic epics and poetry of the cultivated races, such as the Homeric books, the Greek tragedies, the Cyclic poets, the *Kalewala* of the Finns, certain hymns of the *Rigveda*, certain legends of the Brahmanas, the story of the Volsungs,—in these a local and almost historical character is given by the introduction of names of known places, and the adventures are attributed to national heroes.—Odysseus, Œdipus, Sigurd, Wainamoinen, Jason, Pururavas, and others. The whole tone and manners are nobler and more refined in proportion as the literary workmanship is more elaborate.

This theory of the origin of popular tales in the fancy of peoples in the savage condition (see MYTHOLOGY), of their survival as märchen among the peasantry of Indo-European and other civilized races, and of their transfiguration into epics, could only be worked out after the discovery that savage and civilized popular tales are full of close resemblances. These resemblances, when only known to exist among Indo-European peoples, were explained as part of a common Aryan inheritance, and as the result of a malady of language. This system, when applied to myths in general, has already been examined (see MYTHOLOGY). According to another view, märchen everywhere resemble each other because they all arose in India, and have thence been borrowed and transmitted. For this theory consult Benfey's *Panchatantra* and M. Cosquin's *Contes de Lorraine* (Paris, 1886). In opposition to the Aryan theory, and the theory of borrowing from India, the system which is here advocated regards popular tales as kaleidoscopic arrangements of comparatively few situations and incidents, which again are naturally devised by the early fancy. Among these incidents may be mentioned, first, kinship and intermarriage between man and the lower animals and even inorganic phenomena. Thus a girl is wooed by a frog, pumpkin, goat, or bear, or elephant, in Zulu, Scotch, Walachian, Eskimo, Ojibway, and German märchen. This incident is based on the lack of a sense of difference between man and the things in the world which is prevalent among savages (see MYTHOLOGY). Other incidents familiar in our nursery tales (such as "Cinderella" and "Puss in Boots") turn on the early belief in metamorphosis, in magic, in friendly or protecting animals (totems or beast manitous). Others depend on the early prevalence of cannibalism (compare Grimm, 47, "The Juniper Tree"). This recurs in the mad song of Gretchen in *Faust*, concerning which a distinguished student writes, "This ghost of a ballad or rhyme is my earliest remembrance, as crooned by an old East-Lothian nurse." (Compare Chambers's *Popular Rhymes of Scotland*, 1870, p. 49.) The same legend occurs among the Bechuanas, and is published by Casalis. Yet another incident springs from the taboo on certain actions between husband and wife, producing the story of Cupid and Psyche (see Lang's *Custom and Myth*, 1884, p. 64). Once more, the custom which makes the youngest child the heir is illustrated in the märchen of the success, despite the jealousy of the elders, of Cinderella, of the Zulu prince (Callaway's *Tales from the Amazulu*, pp. 64, 65), and in countless other märchen. In other cases, as in the world-wide märchen corresponding to the Jason epic, we seem in presence of an early romantic invention,—how diffused it is difficult to imagine. Moral lessons, again, are inculcated by the numerous tales which turn on the duty of kindness, or on the impossibility of evading fate as announced in prophecy. In opposition to the philological explanation of the story of Œdipus as a nature-myth, this theory of a collection of incidents illustrative of moral lessons is admirably set forth in Prof. Cauparetti's *Edipo e la Mitologia Comparata* (Pisa, 1867).

On a general view, then, the stuff of popular tales is a certain number of incidents and a certain set of combinations of these incidents. Their strange and irrational character is due to their remote origin in the fancy of men in the savage condition; and their wide distribution is caused, partly perhaps by oral transmission from people to people, but more by the tendency of the early imagination to run everywhere in the same grooves. The narratives, in the ages of heroic poetry, are elevated into epic song, and in the Middle Ages they were even embodied in legends of the saints. This view is maintained at greater length, and with numerous illustrations, in the introduction to Mrs. Hunt's translation of Grimm's *Kinder- und Haus-Märchen*, and in *Custom and Myth*, already referred to.

A complete bibliography of the literature of popular tales would fill many pages. The reader who is curious about savage popular tales may turn to Theal's *Kaffir Folk Lore* (2d ed., London, 1886); Callaway's *Nursery Tales of the Amazulu* (London, 1868); Schoolcraft's *Algic Researches*; Gill's *Myths and Tales of the South Pacific*; Petitot's *Traditions Indiennes* (1886); Shortland's *Maori Religion and Mythology*

(London, 1882); The *South African Folk Lore Record;* the *Folk Lore Record* (London, 1879–85, Malagasy stories); Rink's *Tales and Traditions of the Eskimo;* Bleek's *Hottentot Tales and Fables* (London, 1864); Castrén's *Samoyedische Märchen;* and Leland's *Algonquin Legends* (London, 1884). For European tales, the bibliography in the translation of Grimm, already referred to, may be used, and the Maisonneuve collection, *Les Littératures populaires* may be recommended. The names of Liebrecht, Köhler, Dasent, Ralston, Nigra, Pitré, Cosquin, Afanasief, Gaidoz, Sébillot, may serve as clues through the enchanted forest of the nursery tales of Europe.[1] (A. L.)

TALFOURD, Sir Thomas Noon (1795–1854), was at once eminent as a lawyer, as a writer, and as a member of a brilliant and polished society. He had the faculty of winning friendships; so sympathetic indeed was his nature that he unconsciously biased many of the most acute among his acquaintances towards an estimate of his genius as an author—more especially as a dramatist—hardly commensurate with what more impartial criticism has decided to be his just meed of praise. But, though even his most excellent work in literature has now ceased to be generally cared for, his poetry must always be interesting to the literary student.

The son of a brewer in good circumstances, Talfourd was born on January 26, 1795, at Doxey, near Stafford (some accounts mention Reading). He received his early education, first at an institution near Hendon, and later at the Reading grammar-school under Dr. Valpy. Here, it is said, he acquired his taste for dramatic poetry, presumably under the guidance of Dr. Valpy. At the age of eighteen the lad was sent to London to study law under Mr. Chitty, the special pleader. Early in 1821 he joined the Oxford circuit, having been called to the bar at the Middle Temple in February of that year. When, twelve years later, he was created a serjeant-at-law, and when again he in 1849 succeeded Mr. Justice Coltman as judge of the Court of Common Pleas, he attained these distinctions more perhaps for the zeal and laborious care which he invariably displayed in his conduct of the cases confided to him than on account of any brilliance of forensic talent or of any marked intellectual subtlety. A parliamentary life had always had an attraction for him, and at the general election in 1835 he was returned for Reading. This seat he retained for close upon six years, and he was again returned in 1847. In the House of Commons he was no mere ornamental member. Those efforts of his which have most interest for us of later date were made on behalf of the rights of authors, for whose benefit he introduced the International Copyright Bill; his speech on this subject was considered the most telling made in the House during that session. The bill met with strong opposition, but Talfourd had the satisfaction of seeing it ultimately pass into law in 1842, albeit in a greatly modified form.

At the period of his elevation to the bench he was created a knight, and thenceforward his life was, in the intervals of his professional labors, devoted to scholarly and literary pursuits. From his school days he had entertained dreams of attaining eminence as a writer; and to the last he remained a diligent student of literature, ancient and modern. During his early years in London Talfourd found himself forced to depend—in great measure, at least—upon his literary exertions. He was at this period on the staff of the *London Magazine*, and was an occasional contributor to the *Edinburgh* and *Quarterly* reviews, the *New Monthly Magazine*, and other periodicals; while, on joining the western circuit, he acted as law reporter to *The Times*. His legal writings on matters germane to literature are excellent expositions, animated by a lucid and sufficiently telling, if not highly polished, style. Among the best of these are his article "On the Principle of Advocacy in the Practice of the Bar" (in the *Law Magazine*, January, 1846); his *Proposed New Law of Copyright of the Highest Importance to Authors* (1838); *Three Speeches delivered in the House of Commons in Favor of an Extension of Copyright* (1840); and his famous *Speech for the Defendant in the Prosecution, the Queen* v. *Moxon, for the Publication of Shelley's Poetical Works* (1841).

But Talfourd cannot be said to have gained any position among men of letters until the production of his tragedy *Ion*, which was privately printed in 1835, and produced in the following year at Covent Garden theatre. The tragedy was also well received in America, and it met with the honor of reproduction at Sadler's Wells in December, 1861. This dramatic poem, its author's masterpiece, turns upon the voluntary sacrifice of Ion, king of Argos, in response to the Delphic oracle, which had declared that only with the extinction of the reigning family could the prevailing pestilence incurred by the deeds of that family be removed. As a poem *Ion* has many high qualities. The blank verse, if lacking the highest excellence, is smooth and musical, and the lines are frequently informed with the spirit of genuine poetry; the character of the high-souled son of the Argive king is finely developed, and the reader is affected throughout by that same sense of the relentless working and potency of destiny which so markedly distinguishes the writings of the Greek dramatists.

Two years later, at the Haymarket theatre, *The Athenian Captive* was acted with moderate success. In 1839 *Glencoe, or the Fate of the Macdonalds*, was privately printed, and in 1840 it was produced at the Haymarket; but this home drama is indubitably much inferior to his two classic plays. *The Castilian* (1853) did not excite a tenth part of the interest called forth by *Ion*. Before this he had produced various prose writings other than those already referred to,—among them his "History of Greek Literature," in the *Encyclopædia Metropolitana*.

Besides the honor of knighthood and his various legal distinctions, Talfourd held the honorary degree of D.C.L. from the university of Oxford. He died in court during the performance of his judicial duties, at Stafford, on March 13, 1854.

In addition to the writings above-mentioned, Talfourd was the author of *The Letters of Charles Lamb with a Sketch of his Life* (1837); *Recollections of a first Visit to the Alps* (1841); *Vacation Rambles and Thoughts*, comprising recollections of three Continental tours in the vacations of 1841, 1842, and 1843 (2 vols., 1844); and *Final Memorials of Charles Lamb* (1849–50).

TALISMAN. See Amulet.

TALLAGE, or Talliage (from the French *tailler*, *i.e.*, a part cut out of the whole), appears to have signified at first a tax in general, but became afterwards confined in England to a special form of tax, the assessment upon cities, boroughs, and royal demesnes—in effect, a land tax. Like Scutage (*q.v.*), tallage was superseded by the subsidy system in the 14th century. The last occasion on which it was levied appears to be the year 1332. The famous statute of 25 Edw. I. (in some editions of the statutes 34 Edw. I.) *De Tallagio non Concedendo*, though it is printed among the statutes of the realm, and was cited as a statute in the preamble to the Petition of Right in 1627, and by the judges in John Hampden's case in 1637, is probably an imperfect and unauthoritative abstract of the *Confirmatio Cartarum*. The first section enacts that no tallage or aid shall be imposed or levied by the king and his heirs without the will and assent of the archbishops, bishops, and other prelates, the earls, barons, knights, burgesses, and other freemen in the kingdom. *Tallagium facere* was the technical term for rendering accounts in the exchequer, the accounts being originally kept by means of *tallies* or notched sticks. The tellers (a corruption of *talliers*) of the exchequer were at one time important financial officers. The system of keeping the national accounts by tallies was abolished by 23 Geo. III. c. 82, the office of teller by 57 Geo. III. c. 84.

TALLEYRAND DE PÉRIGORD, CHARLES MAURICE (1754–1838), created by Napoleon a prince of the empire under the title of the Prince de Bénévent, was born at Paris on 2d February, 1754. His father, who was of a younger branch of the princely family of Chalais, was an officer in the army of Louis XV., and his mother, also of noble family, was a member of the royal household at Versailles. An accident in infancy rendered Talleyrand lame for life, and changed his whole career. His upbringing was, in accordance with the fashionable heartlessness of the day, entirely left to strangers; and while a boy he was, in consequence of his lameness, formally deprived by a *conseil de famille* of his rights of primogeniture,—his younger brother, the Comte d'Archambaud, taking his place; and he was destined for the church. He keenly felt the blow, but was powerless to avert it; and he used his enforced profession only as a stepping-stone to his ambition, always despising it, and coolly and defiantly forsaking it when he found it an embarrassment.

When he was removed from the country he was sent to the Collége d'Harcourt, where he speedily distinguished himself; and in 1770, when sixteen years of age, he became an inmate of the Séminaire de St. Sulpice, his education being completed by a course in the Sorbonne. Much as Talleyrand despised the church as a career, he never ceased highly to appreciate theology as a training, and he publicly testified to its value to the statesman and specially to the diplomatist. While achieving distinction as a student, he carefully cultivated such society as might promote his advancement; and it was in the circle of Madame du Barry that his cynicism and wit, reported by her to the king, gained him the position of abbé. To his arts of manner were added, not only his advantages of birth and scholarship, but a penetrating judgment of men and affairs, a subtle audacity, and a boundlessly selfish ambition. As early as 1780 we find this *abbé malgré lui* to have reached the important position of "agent-general" of the French clergy. His ability and his flagrant immorality alike rendered him a marked man, and the latter did not prevent his appointment, in accordance with his father's dying request to the king, as bishop of Autun in January, 1789. The clergy of his own diocese immediately elected him a member of the states-general; and he delivered before his constituents one of the most remarkable speeches which the crisis produced, containing a sagacious and statesmanlike programme of the reforms which the condition of France demanded. He thus entered the assembly as one of its leaders.

The states-general had hardly met ere Talleyrand's influence was called into play. He successfully urged the clergy to yield to the demand of the commons that the three estates should meet together; and the nobles could thereafter only follow the example thus set. On the question of the extent of the assembly's authority he again sided with the popular leaders. As a financier of great foresight and power he soon became justly celebrated; and his position in the assembly may be estimated by his appointment as one of a committee of eight to frame the project of a constitution. All his previous successes were, however, eclipsed by the daring with which he attacked the rights and privileges of his own order. He had seconded the proposals that the clergy should give up their tithes and plate for the benefit of the nation, and on 10th October, 1789, he himself proposed a scheme whereby the landed property of the church should be confiscated by the state. On 2d November, after violent debates, his project was carried, and the old clergy thereafter ranked him as an enemy. But his general popularity so much increased that he was charged by the national assembly to prepare a written memoir in defence of its labors; and the manifesto, read on February 10, 1790, was received with great approval throughout the country. On the 16th he was elected president of the assembly for the usual brief term. On various subjects he was now looked up to as an authority,—on education, on electoral and ecclesiastical reform, on banking, and on general finance. His career as a diplomatist had not yet begun.

On July 14, 1790, Talleyrand, at the head of 300 clergy, assisted at the fête in the Champ de Mars in commemoration of the fall of the Bastile, and publicly blessed the great standard of France. By this time, however, the dispute as to the civil constitution of the clergy had broken out, the decision of the assembly being resisted by the king, backed by the pope. When in November the king yielded, Talleyrand boldly took the required oath, only two bishops following his example. New bishops were elected by the assembly, and these he, in open defiance of the church, consecrated. In the end of April, 1791, he was suspended from his functions and excommunicated by the pope. Without a moment's hesitation Talleyrand abandoned his profession, which he never afterwards resumed. He had been false to its vows, and had scandalized it by his shameless life. It was only in the preceding February that he had, in declining nomination for the archbishopric of Paris, felt, indiscreetly enough and contrary to his usual practice, the necessity of writing to the *Moniteur* a hypocritical confession of his gambling propensities, stating his gains at 30,000 francs [$5790]. Although in 1801 the excommunication was recalled, it was nearly half a century after his first act of defiance ere he became personally reconciled to the church, and then only when he was at the point of death.

On purely political lines, however, Talleyrand's career became more and more celebrated. In the beginning of the same month of April, 1791, his friend Mirabeau having just died, he was appointed to succeed him as a director of the department of Paris, a position which still further increased his influence in the circles of the metropolis. On the flight of the king in June, Talleyrand leaned at first and cautiously towards the duke of Orleans, but finally declared for a constitutional monarchy with Louis XVI. still on the throne. Ere the constitutional assembly brought its existence to a close on 14th September, he unfolded before it his magnificent scheme of national education, which, in the words of Sir Henry Bulwer, "having at one extremity the communal school and at the other the Institute, exists with but slight alterations at this very day." The assembly had voted that none of its members should be members of the new legislative body, so that Talleyrand was free; besides, events were hurrying on with strange and critical rapidity; and Talleyrand left France for England, reaching London in the end of January, 1792. With this visit his diplomatic career may be said to have begun.

He was not formally accredited, but had in his pocket an introduction to Lord Grenville by Delessart the foreign minister; the king himself was aware of his mission, the ostensible object of which was to conciliate England. Talleyrand for his part shared the ulterior views of Narbonne, the minister of war, that it would be for the advantage of his country to divert its energies, which were morbidly directed to its internal troubles, into another channel, and to precipitate an Austrian war. Although received well in London society, he found the want of official credentials a fatal obstacle to his diplomatic negotiations, and he returned to Paris, whence he was almost immediately again despatched to the English court under much more favorable conditions. He was nominally only attendant with De Chauvelin, the minister plenipotentiary, but he was really the head of the embassy, and he carried with him a letter of Louis XVI. to George III. At this time, indeed, Talleyrand's relations with Louis were very close,—far closer than he afterwards cared or dared to avow. All, however, was of no avail. The startling course of the Revolution made the English look askance upon his mission, and he returned baffled to Paris, where he arrived shortly before the *coup d'état* of the 10th of August. But this place, where his wariest manœuvres were outdone by the rapidity of the popular movements, and where at any turn of affairs he might lose his head, was not to his liking; and by the middle of September, he is for the third time in London. It is characteristic of the man—of the dexterity as well as audacity of his intrigue—that he who had but shortly before carried with him a letter of favor from Louis XVI. was, now that royalty was abolished, the bearer of a specific passport—"going to London by our orders"—under the hand of Danton. Equally characteristic is the express falsehood with which he opens his negotiations: he writes at once to Lord Grenville, "I have at this time absolutely no kind of mission in England"—he was selling his library and seeking repose. His courtesies were not returned; and, although he succeeded in making friends in certain high quarters, he was, in the end of January, 1794, under the provisions of the Alien Act, ordered to leave England. Fortified with an introduction by Lord Lansdowne to Washington, he sailed for the United States.

A decree of the convention had issued against Talleyrand during his stay in England. He was an *émigré.* But as the excesses of the period drew to a close the proscription was recalled on the appeal of Chénier, who founded it on Talleyrand's relations with Danton and his mission to England in the service of the Revolution! On July 25, 1795, he arrived at Hamburg, whence he passed to Berlin, and, after a short stay there, to Paris. He was received with enthusiasm in the circles of fashion and intrigue. He would have been eagerly welcomed by any of the political parties as a strength; but the Directory was in power, and he supported it. Within the Directory he supported Barras, as against his compeers. He was thus a moderate constitutionalist and in the way of advancement.

During his absence from France he had been elected a member of the Institute. He was now elected its secretary. In this capacity he read before it two memoirs—one on the "commercial relations of the United States with England," and the other "on the advantages of withdrawing from new colonies in present circumstances." These memoirs exhibit Talleyrand at the very maturity of his powers, and are sufficient to establish his position as one of the most far-seeing and thoughtful statesmen that France ever possessed. The first paper shows how, in spite of the War of Independence, the force of language, race, and interest must in his view bind England and the States together as natural allies; and it contains that remarkable passage (which once read is never forgotten) in which the civilization of America is described as exhibited in space as well as in time,—as the traveller moves westward from State to State he appears to go backward from age to age. The papers, which were read in April and July of 1797, made his claim to state recognition irresistible, and towards the end of the latter month he was appointed to the post of foreign minister.

He had been carefully scanning the political situation, and he accurately foresaw that the Directory, which represented no one set of opinions, but only a vain compound of all, could not stand against unity of policy backed by force, and in the meantime could be manipulated. Thus with a brutal swiftness its personnel becomes changed. Barras with his sluggish moderation remains; but, behind and through him, it is the dexterous purpose of Talleyrand that is at work. This is the first characteristic of his administration. Its second is the ability which he displays in his communications with the diplomatic service, in view of the rupture with England. Its third is the shamelessly corrupt manner in which he approaches the American ambassadors on the subject of the seizure of certain ships, on the conclusion of a commercial treaty between England and the States, putting himself in his public and powerful position at their service,—if the bribe were suitably large. And its fourth is that he is hardly in the chair of office until he has shrewdly selected Bonaparte as the object of his assiduous flatteries, writing to him in semi-confidence, and laying the basis of their future intimacy. But his first term of office was short: the American ambassadors spurned his offer and let his conduct be publicly known, with the result that for this and other reasons he resigned his post. Public opinion was outraged. His official corruption, however, was not ended, for Talleyrand turned everything into gold; in his later diplomacy also he could always be bought; and this public immorality was but too faithfully reflected in his private life, in which gambling was his passion and a source of his vast wealth.

Out of office, but still pulling the strings of the Directory, he awaited the arrival of Napoleon in Paris, and it was his hand which was most powerful in shaping the events of the 18th and 19th Brumaire—9th and 10th November, 1799. He reconciled Sieyès to Bonaparte; a majority of the Directory—Sieyès, Ducos, and at last at his persuasion even Barras—resigned; the Directory collapsed, and the consulate was established (see NAPOLEON and SIEYÈS). Napoleon was the first and Talleyrand the second man in France.

He was now an absolutist, the whole drift of his influence being in the direction of consolidating, under whatever title, the power of Bonaparte. For many years henceforward Talleyrand's career is part of the general history of France. He is soon again foreign minister; and he is acknowledged to have been the ablest diplomatist of an age when diplomacy was a greater power than it has ever been before or since. To him falls a full share of responsibility for the kidnapping and murder of the Duc d'Enghien in March, 1804 (see SAVARY). He had assisted at the councils when the atrocity was planned, and he wrote to the grand-duke justifying the seizure of the prince while on Baden territory. His hand in the matter was of course concealed. But, when one advised him to tender his resignation, he demurely remarked, "If, as you say, Bonaparte has been guilty of a crime, that is no reason why I should be guilty of a folly." In other and more agreeable directions he had prostrated himself before Napoleon's purposes, approving among other things of the policy of the Concordat (15th July, 1801), and securing thereby the recall of his excommunication. To the Pope's grateful brief, which gave him liberty "to administer all civil affairs," he coolly gave a wide interpretation, and he shortly thereafter married. He of course supported and defended first the consulship for life and then the crowning of the emperor.

By and by, however, a change comes over his political attitude, and it is not long ere Napoleon detects it. This change we date, with Sainte-Beuve, from the end of January, 1809. Before the peace of Tilsit, July 8, 1807, from Jena onwards, he had personally accompanied the great conqueror; after it they stood apart, for the statesman saw in those brilliant but ceaseless conquests the prelude to the ruin of his master and his country. He was now prince of Benevento, and he withdrew from the ministry, receiving at his own desire the title of vice-grand-elector of the empire. Yet he had not disapproved of the Spanish war; the young princes had even been entrusted to his surveillance at his country house at Valençay. But anything might have happened to the emperor in Spain, and Talleyrand had evidently been calculating the chances of the future. So at the date stated the explosion occurs, Napoleon pouring upon Talleyrand all the fury of his invective, reproaching him with the affair of the Duc d'Enghien, and clamoring to know where his enormous wealth had come from,—how much he had gained at play or on the stock exchange, and what was the sum of his bribes by foreign powers. Over and over again such scenes are repeated, the burden of the fierce reproaches being always the same; but Talleyrand stands impassive as a statue, remarking once, but not till he is out of the room, and is limping away, "What a pity that such a great man has been so badly brought up!" or sending in, at another time, a resignation, which of course is not accepted. The reproaches of the emperor were only too well founded, his minister having reaped a vast harvest from the smaller powers at the formation of the Rhenish Confederation; it is indeed recorded that Talleyrand once put a figure upon his gains in this department of corruption—the figure being no less than sixty million francs [$11,580,000].

It is undoubtedly to his credit, however, that he steadily resisted a warlike policy, and that he was particularly opposed to the Russian invasion. He was occasionally employed in diplomatic negotiations, and was even again offered the post of foreign minister if he would give up that of vice-grand-elector. This offer, which would have placed him at the mercy of Napoleon, he declined, and the breach between the two widened. Before the events of 1814 his hotel had become the centre of anti-Napoleonic intrigue; as the crisis approached he communicated with the allies; when it was at hand he favored a regency, and appeared anxious that Marie Louise should remain in Paris; and when this was abandoned he carefully arranged a feigned departure himself, but that his carriage should be turned back at the city gates; he did return; and the emperor Alexander was his guest at the Hôtel Talleyrand! The revolution was his work; and his nominee Louis XVIII. ascended the throne. For the third time, and again under a new master, he was appointed foreign minister. It would be difficult to overestimate the splendid services which he now rendered to France. In Paris, on 23d April, the treaty was concluded under which the soldiers of the allies were to leave French soil; and Talleyrand successfully urged that the territory of France should be the enlarged territory of 1792, and also that the great art treasures of which so many European cities had been despoiled should remain in Paris. A final treaty of peace between Europe and France was concluded on 30th May, and in September the congress of Vienna assembled. It was the scene of Talleyrand's greatest triumphs. He succeeded single-handed in breaking up the confederation of the allies, and in reintroducing the voice of France into the deliberations of the European powers. Further, on January 3, 1815, a secret treaty was concluded between Austria, France, and England.

When Napoleon escaped from Elba and advanced towards Paris, Louis XVIII. retired to Ghent. Although the congress of Vienna was thus broken up, Talleyrand made no haste to follow him thither. He was puzzled, and remained so during the Hundred Days. He despised Louis, and an early approach to Bonaparte was out of the question. He therefore coolly betook himself to Carlsbad, remarking, when an explanation was asked for, that the first duty of a diplomatist after a congress was to attend to his liver! Waterloo of course decided him. He appeared at Ghent, and was but coldly received. The foreign powers, however, intervened, conscious after Vienna of Talleyrand's value; and, among others, Wellington insisted that the great diplomatist must be taken into the councils of Louis,—with the result that he became prime minister at the second restoration. But his position was one of extreme difficulty. The king disliked him: there were scenes bordering on violence in the royal presence; the Russian emperor intimated his hostility to him; he shared the odium of having a man like Fouché for a colleague; Chateaubriand and his party hated and beset him. Fortunately an excuse of a broad and national kind soon presented itself. He objected to the conditions which the allies were imposing upon France, refused to sign the treaty, and on 24th September resigned office.

He retired into private life, in which he remained for fifteen years. He only spoke in the House of Peers three times during this period,—twice (1821 and 1822) in favor of the liberty of the press, and once (1823) to protest against the Spanish war. But in 1830, when Charles X.'s reign was evidently imperilled, he again is at the centre of intrigue; and it is actually at his private but urgent suggestion that Louis Philippe heads the revolution, taking, to begin with, the title of lieutenant-general of the kingdom. Declining the post of foreign minister, he proceeded to London as ambassador, conducting himself and serving his country with his usual consummate skill. He returned crowned with success after the formation of the Quadruple Alliance. In November, 1834, he resigned, and quitted public life forever.

He emerged from his retirement on March 3, 1838, to pronounce before the institute the éloge of Reinhard, and in so doing to treat of diplomacy in general, and to suggest an indirect but adroit apology for his own career. He was received with unbounded enthusiasm by the élite of French literature and society—Cousin even exclaiming that the éloge was worthy of Voltaire. His last illness, which had by this time shown itself, soon prostrated him. He was visited on his death-bed by crowds of celebrities, including the king. He died on May 17, 1838, at the great age of eighty-four. He is buried at Valençay.

According to his desire, his memoirs under his own hand will not appear till 1890.

There is a considerable body of anonymous and untrustworthy literature both in French and English on the subject of this sketch. For the earlier part of Talleyrand's career, see the general literature of the Revolution; for the Napoleonic, the general histories, including especially the *Memoirs* of the Duc de Rovigo; for the third and last, also the general histories, and especially the *Correspondence between Talleyrand and Louis XVIII.*, edited by Pullain (1880; transl. into English 1881), and the *Memoirs* of Guizot. References abound to the private life of Talleyrand, and on it see also the *Histoire Politique et Vie Intime*, by G. Touchard-Lafosse (1848), and the *Souvenirs Intimes sur M. de Talleyrand*, by Amedée Pichot (1870). The student must be on his guard in perusing most of this last-mentioned literature. For many years the *Histoire Politique et Privée*, by G. Michaud (1853), stood practically uncorrected, although evidently a studied and bitter attack. The view taken by Louis Blanc in his *Dix Ans* (translated into English in 1845) is also quite distorted, and if one wishes to see a complete misreading of Talleyrand's career it can be found in Blanc's tenth chapter of his fifth book. Sir Henry Lytton Bulwer rendered great service by his life of Talleyrand, published in his *Historical Characters;* and the worth and accuracy of Bulwer's biography, which was speedily translated into French, has been amply acknowledged by Sainte-Beuve in his valuable treatise (lectures) on Talleyrand, published in 1870. Reference should also be made to Mignet, Bastide, and the *Mémoires Politiques* of Lamartine.

Caution will have to be exercised in reading Talleyrand's autobiography, which will not appear till 1890. The testimony of contemporaries will not be available to check it, and Talleyrand is proved to have presided at the destruction of much documentary evidence implicating himself, *e.g.*, at the moment when the Russian emperor was living at his house. (T. S.)

TALLIEN, Jean Lambert (1769–1820), the chief leader of the party that overthrew Robespierre, was the son of the *maître d'hôtel* of the Marquis de Bercy, and was born in Paris in 1769. The marquis, perceiving the boy's ability, had him well educated, and got him a place as a lawyer's clerk. Being much excited by the first events of the Revolution, he gave up his desk to enter a printer's office, and by 1791 he was overseer of the printing department of the *Moniteur*. While thus employed he conceived the idea of the *journal-affiche*, and from January to May, 1791, he placarded a large printed sheet on all the walls of Paris twice a week under the title of the *Ami des Citoyens*. This enterprise of his, of which the expenses were defrayed by the Jacobin Club, made him well known to the revolutionary leaders; and he made himself still more conspicuous in organizing the great "Fête de la Liberté" on April 15, 1792, in honor of the released soldiers of

Château-Vieux, with Collot d'Herbois. On July 8, 1792, he was the spokesman of a deputation of the section of the Place Royale which demanded from the legislative assembly the reinstatement of Pétion and Manuel, and he was one of the most active popular leaders in the attack upon the Tuileries on 10th August, on which day he was appointed secretary or clerk to the revolutionary commune of Paris. In this capacity he exhibited an almost feverish activity; he perpetually appeared at the bar of the assembly on behalf of the commune; he announced the massacres of September in the prisons in terms of praise and apology; and he sent off the famous circular of 3d September to the provinces, recommending them to do likewise. At the close of the month he resigned his post on being elected, in spite of his youth, a deputy to the Convention by the department of Seine-et-Oise, and he commenced his legislative career by defending the conduct of the commune during the massacres. He took his seat upon the Mountain, and showed himself one of the most vigorous Jacobins, particularly in his defence of Marat; he voted for the execution of the king, and was elected a member of the Committee of General Security on January 21, 1793. After a short mission in the western provinces he returned to Paris, and took an active part in the *coups de'état* of 31st May and 2d June, which resulted in the overthrow of the Girondins. For the next few months he remained comparatively quiet, but on September 23, 1793, he was sent with Ysabeau on his famous mission to Bordeaux. This was the very month in which the Terror was organized under the superintendence of the Committees of Public Safety and General Security, and Bordeaux was one of the cities selected to feel its full weight. Tallien showed himself one of the most vigorous of the proconsuls sent over France to establish the Terror in the provinces; though with but few adherents, he soon awed the great city into quiet, and kept the guillotine constantly employed. It was at this moment that the romance of Tallien's life commenced. Among his prisoners was Theresa, Comtesse de Fontenay, the daughter of the great Spanish banker Cabarrus, the most beautiful and fascinating woman of her time, and Tallien not only spared her life but fell deeply in love with her. She quickly abated the fierceness of his revolutionary ardor, and from the lives she saved by her entreaties she received the name of "Our Lady of Pity." This mildness, however, displeased the members of the committees; Tallien was recalled to Paris; and Madame de Fontenay was imprisoned there. Danton and his friends had but just fallen, and the members of the committees were half afraid to strike again at the moderates, so Tallien was spared for the time, and was even elected president of the Convention on March 24, 1794. But the Terror could not be maintained at the same pitch: Robespierre began to see that he must strike at many of his own colleagues in the committees if he was to carry out his theories, and Tallien was one of the men condemned with them. They determined to strike first, and on the great day of Thermidor it was Tallien who, urged on by the danger in which his beloved lay, opened the attack upon Robespierre. The movement was successful; Robespierre and his friends were guillotined; and the young Tallien, as the leading Thermidorian, was elected to the Committee of Public Safety. Now came the great months of his career: he showed himself a vigorous Thermidorian; he was instrumental in suppressing the Revolutionary Tribunal and the Jacobin Club; he attacked Carrier and Lebon, the proconsuls of Nantes and Arras; and he fought bravely against the insurgents of Prairial. In all these months he was supported by his Theresa, whom he married on December 26, 1794, and who became the leader of the social life of Paris. His last political achievement was in July, 1795, when he was present with Hoche at the destruction of the army of the émigrés at Quiberon, and ordered the executions which followed. After the close of the Convention Tallien's political importance came to an end, for, though he sat in the Council of Five Hundred, the moderates attacked him as terrorist, and the extreme party as a renegade. Madame Tallien also got tired of him, and became the mistress of the rich banker Ouvrard. Bonaparte, however, who is said to have been introduced by him to Barras, took him to Egypt in his great expedition of June, 1798, and after the capture of Cairo he edited the official journal there, the *Décade Égyptienne*. But Menou sent him away from Egypt, and on his passage he was captured by an English cruiser and taken to London, where he had a good reception among the Whigs and was well received by Fox. On returning to France in 1802 he got a divorce from his unfaithful spouse (who eventually married the Prince de Chimay), and was left for some time without employment. At last, through Fouché and Talleyrand, he got the appointment of consul at Alicante, and remained there until he lost the sight of one eye from yellow fever. On returning to Paris he lived on his half-pay until 1815, when he received the especial favor of not being exiled like the other regicides. His latter days were spent in the direst poverty; he had to sell his books to get bread. He died at Paris on November 16, 1820.

TALLIS (**TALLYS**, **TALYS**, or **TALLISIUS**), **THOMAS** (*c.* 1515–1585), justly styled "the father of English cathedral music," was born, as nearly as can be ascertained, about the year 1515. The history of his youth is involved in some obscurity; there seems, however, but little doubt that, after singing as a chorister at old Saint Paul's under Thomas Mulliner, he obtained a place among the children of the chapel royal. His next appointment was that of organist at Waltham abbey, where, on the dissolution of the monastery in 1540, he received in compensation for the loss of his preferment, 20s. [$4.86] for wages and 20s. [$4.86] for reward. An interesting relic of this period of his career is preserved in the library of the British Museum, in the form of a volume of MS. treatises on music, once belonging to the abbey, on the last page of which appears his autograph, "Thomas Tallys," with the final letter prolonged into an elaborate flourish—the only specimen of his handwriting now known to exist.

Not long after his dismissal from Waltham, Tallis was appointed a gentleman of the chapel royal; and thenceforward he labored so zealously for the advancement of his art that his genius has left an indelible impression upon the English school, which owes more to him than to any other composer of the 16th century, and in the history of which his name plays a very important part indeed.

One of the earliest compositions by Tallis to which an approximate date can be assigned is the well-known *Service in the Dorian Mode*, consisting of the *Venite*, *Te Deum*, *Benedictus*, *Kyrie*, *Nicene Creed*, *Sanctus*, *Gloria in Excelsis*. *Magnificat*, and *Nunc Dimittis*, for four voices, together with the *Preces*, *Responses*, *Paternoster*, and *Litany*, for five, all published for the first time, in the Rev. John Barnard's *First Book of Selected Church Music*, in 1641, and reprinted, with the exception of the *Venite* and *Paternoster*, in Boyce's *Cathedral Music* in 1760.[1] That this work was composed for the purpose of supplying a pressing need, after the publication of the second prayer-book of King Edward VI. in 1552 there can be no reasonable doubt; and its perfect adaptation to its intended purpose is sufficiently proved by the fact that, for more than three hundred years, its claim to occupy the first and highest place among compositions of its class has been undisputed. Written in the style known among Italian composers as *lo stile famigliare*, *i.e.*, in simple counterpoint of the first species, *nota contra notam*, with no attempt at ingenious points of imitation, or learned complications of any kind—it adapts itself with equal dignity and clearness to the expression of the verbal text it is intended to illustrate, bringing out the sense of the words so plainly that the listener cannot fail to interpret them aright, while its pure rich harmonies tend far more surely to the excitement of devotional feeling than the marvellous combinations by means of which too many of Tallis's contemporaries sought to astonish their hearers, while forgetting all the loftier attributes of their art. In this noble quality of self-restraint the *Litany* and *Responses* bear a close analogy to the *Improperia* and other similar works of Palestrina, wherein, addressing himself to the heart rather than to the ear, the *princeps musicæ* produces the most thrilling effects by means which, to the superficial critic, appear almost puerile in their simplicity, while those who are able to look beneath the surface discern in them depths of learning such as none but a very highly cultivated musician can appreciate. Of this profound learning Tallis possessed an inexhaustible store; and the rich resources it opened to his genius not only placed his compositions on a level with those produced by the best of his Italian and Flemish contemporaries, but enabled him to raise the English school itself to a height which it had never previously attained, and which, nevertheless, it continued to maintain undiminished until the death of its last representative, Orlando Gibbons, in 1625. Though this school is generally said to have been founded by Dr. Tye, there can be no doubt that Tallis was its greatest master, and that it was indebted to him alone for the infusion of new life and vigor which prevented it from degenerating, as some of the earlier Flemish schools had done, into a mere vehicle for the display of fruitless erudition. Tallis's ingenuity far surpassed that of his most erudite contemporaries; but he never paraded it at the expense either of intrinsic beauty or truthfulness of expression. Like every other great musician of the period, he produced occasionally works confessedly intended for no more exalted purpose than the exhibition of his stupendous skill, one of the most remarkable characteristics of which was the apparent ease with which it disposed of difficulties that, to composers of ordinary ability, would have proved insurmountable. In his canon, *Miserere nostri*, the intricacy of the contrapuntal devices seems little short of miraculous; yet, so smooth and flowing is the effect produced by their dizzy involutions, that no one unacquainted with the secret of their construction would suspect the presence of any unusual element in the composition. In his motet, *Spem in alium non habui*, written for forty voices disposed in eight five-part choirs, each singer is intrusted with a part, agreeable and interesting in itself, yet never for a moment interfering with any one of the thirty-nine equally interesting parts with which it is associated. These *tours de force*, however, though approachable only by the greatest contrapuntists living in an age in which counterpoint was cultivated with a success that has never since been equalled, serve to illustrate one phase only of Tallis's many-sided genius, which shines with equal brightness in the eight psalm-tunes (one in each of the first eight modes) and unpretending little *Veni Creator*, printed in 1567 at the end of Archbishop Parker's *First Quinquagene of Metrical Psalms*, and many other compositions of like simplicity.

---

[1] Boyce's unaccountable omission of the very beautiful *Venite* is a misfortune which cannot be too deeply deplored, since it has led to its consignment to almost hopeless oblivion.

In 1575 Tallis and his pupil William Byrd—as great a contrapuntist as himself, though by no means his equal in depth of expression—obtained from Queen Elizabeth royal letters patent granting them the exclusive right of printing music and ruling music-paper for twenty-one years; and, in virtue of this privilege, they issued, in the same year, a joint work, entitled *Cantiones quæ ab argumento Sacræ vocantur, quinque et sex partium*, containing sixteen motets by Tallis and eighteen by Byrd, all of the highest degree of excellence. Some of these motets, adapted to English words, are now sung as anthems in the Anglican cathedral service. But no such translations appear to have been made during Tallis's lifetime; and there is strong reason for believing that, though both he and Byrd outwardly conformed to the new religion, and composed music expressly for its use, they remained Catholics at heart to the end of their days.

Tallis's contributions to the *Cantiones Sacræ* were the last of his compositions published during his lifetime. He did not, indeed, live to witness the expiration of the patent, though Byrd survived it and published two more books of *Cantiones* on his own account in 1589 and 1591, besides numerous other works. Tallis died November 23, 1585, and was buried in the parish church at Greenwich, where a quaint rhymed epitaph, preserved by Strype, and reprinted by Burney and Hawkins, recorded the fact that he served in the chapel royal during the reigns of Henry VIII., Edward VI., Mary, and Elizabeth. This was destroyed with the old church about 1710; and it was not until about twenty years ago that a copy was placed in the present building. Portraits, professedly authentic, of Tallis and Byrd were engraved by Vandergucht in 1730, for Nicolas Haym's projected *History of Music*, but never published. One copy only is known to exist.

Not very many works besides those already mentioned were printed during Tallis's lifetime; but a great number are still preserved in MS. Unhappily, it is to be feared that many more were destroyed, in the 17th century, during the spoliation of the cathedral libraries by the Puritans. (W. S. R.)

TALLOW is the solid oil or fat of ruminant animals, but commercially it is almost exclusively obtained from oxen and sheep. The fat is distributed throughout the entire animal structure; but it accumulates in large quantities as "suet" in the body cavity, and it is from such suet that tallow is principally melted or rendered. The various methods by which tallow and other animal fats are separated and purified have been dealt with under OILS (see vol. xvii. p. 764). In commerce ox tallow and sheep tallow are generally distinguished from each other, although much nondescript animal fat is also found in the market. Ox tallow occurs at ordinary temperatures as a solid hard fat having a yellowish white color; when fresh and new it has scarcely any taste or smell; but it soon acquires a distinct odor and readily becomes rancid. The fat is insoluble in cold alcohol, but it dissolves in boiling spirit of 0.822 sp. gr. in chloroform, ether, and the essential oils. The hardness of tallow and its melting-point are to some extent affected by the food, age, state of health, etc., of the animal yielding it, the firmest ox tallow being obtained in certain provinces of Russia, where for a great part of the year the oxen are fed on hay. New tallow melts at from 42.5° [108.5° F.] to 43° C., old tallow at 43.5° [110.3° F.], and the melted fat remains liquid till its temperature falls to 33° or 34° C. [91.4° to 93° F.]. Tallow consists of a mixture of two-thirds of the solid fats palmitin and stearin, with one-third of the liquid fat olein. A fluid oil known as tallow oil is obtained from solid tallow by the separation by pressure of the greater part of the olein. To facilitate the separation of the olein, tallow is first melted and just before resolidifying it is mixed with about 10 per cent. of benzine or petroleum spirit. The mixture is then allowed to solidify in flat cakes or slabs, which are placed in press bags and piled between iron plates in a hydraulic press. On the application of pressure the olein mixed with the solvent hydrocarbon flows freely out, leaving a hard dense cake of stearin and palmitin in the bags. The volatile solvents are subsequently driven off by blowing steam through the oil, which remains a turbid fatty fluid from the proportion of solid fats it carries over with it from the hydraulic press. Tallow oil is a useful lubricant and a valuable material for fine soap making, but it is not now abundantly prepared. Mutton tallow differs in several respects from that obtained from oxen. It is whiter in color and harder, and contains only about 30 per cent. of olein. Newly rendered it has little taste or smell, but on exposure it quickly acquires characteristic qualities and becomes rancid. Sweet mutton tallow melts at 46° [114.6° F.] and solidifies at 36° C. [96.8° F.]; when old it does not melt under 49° [120° F.], and becomes solid on reaching 44° [111.2° F.] or 45° C. [113° F.]. It is sparingly soluble in cold ether and in boiling spirit of 0.822 sp. gr.

In early times tallow was a most important candle-making substance, and candles made from this material are still consumed in no inconsiderable quantity, but the greater proportion of the supply is now absorbed by the soap trade; the artificial butter trade which has sprung up since 1872 also takes up large quantities of sweet tallow. Tallow is further used extensively as a lubricant and in leather dressing, etc. It is of course a product of all cattle and sheep-rearing countries, and it forms an important article of export from the United States, the Argentine Republic, and the Australian colonies. Till within the last quarter of a century Russia supplied nearly all the tallow imported into the United Kingdom; but now the imports from that source are on the most meagre scale, although Russian P. Y. C. (pale yellow candle) continues to represent the finest commercial brand.

TALLOWS, VEGETABLE. See OILS, vol. xvii. p. 768.

TALMA, JOSEPH FRANÇOIS (1763–1826), French tragedian, was born at Paris, 15th January, 1763. After attending the Mazarin college, he accompanied his father, who was a dentist, to London, where he studied in the hospitals. While in London he took part in some amateur theatricals, and, his talents at once attracting notice, a professional engagement was offered him. To this, however, his father would not consent, and shortly afterwards he was sent to Paris, where for some years he was assistant to a dentist. His predilection for the drama could not be restrained, and on 21st November, 1787, he made his début at the Comédie Française in *Mahomet*. His efforts from the first won appreciation, but for a considerable time he was restricted to secondary parts. It was in *jeune premier* parts that he first came prominently into notice, and he attained only gradually to his unrivalled position as the exponent of strong and concentrated passion. In 1791 he and other dissentients founded the Théâtre Français de la rue de Richelieu,—a name changed in 1792 to Théâtre de la République, where he won his most striking successes. Talma was among the earliest advocates of realism in scenery and costume, being greatly aided in his reforms by his friend the painter David. He possessed in perfection the physical gifts fitting him to excel in the highest tragic parts, an admirably proportioned figure, a striking countenance, and a voice of great beauty and power, which, after he had conquered a certain thickness of utterance, enabled him to acquire a matchless elocution. At first somewhat stilted and monotonous in his manner, he gradually emancipated himself from all artificial trammels, and became by perfection of art a model of simplicity. Talma enjoyed the intimacy of Napoleon, with whom he had an acquaintance before Napoleon attained greatness; and he was a friend of Chénier, Danton, Camille Desmoulins, and other revolutionists. He made his last appearance 11th June, 1826, and died at Paris 19th October of that year.

Talma was the author of *Mémoires de Le Kain, précédés de Réflexions sur cet Acteur et sur l'Art Théâtral*, contributed to the *Collection des Mémoires sur l'Art Dramatique*. It was published separately at Paris in 1856, under the title *Réflexions de Talma sur Le Kain et l'Art Théâtral*. See *Mémoires de J. F. Talma, écrits par lui-même, et recueillis et mis en ordre sur les papiers de sa famille*, by Alex. Dumas (1856).

TALMUD signifies—(1) "study of and instruction in anything (whether by any one else or by oneself);"[1] (2) "learning acquired;"[2] (3) "style, system;"[3] as such it is synonymous with *Mishnah* in its fifth signification, vol. xvi. p. 526; (4) "theory," in contradistinction to "practice,"[4]—synonymous with *Midrash* in its fourth signification, vol. xvi. p. 298; (5) such interpretation of the Mosaic law as is apparent on the surface thereof and does not necessitate any further disquisition;[5] (6) *Boroitho*, or the non-canonical *Mishnah*;[6] (7) *Gemara*, *i.e.*, the oldest commentary on the canonical *Mishnah*;[7] (8) the texts of *Mishnah* and *Gemara* combined,—the meaning which is the one most commonly attached to the term *Talmud*. Although the word *Talmud* is not to be found in the Bible, there can be little doubt that it is a classical Hebrew term, as may be seen by the analogy of *Taḥănūn*, "supplication," *Tanḥūm*, "consolation," etc.

Recensions of the Talmud.—The Talmud exists in two recensions,—the Palestinian, commonly, but by mistake, called *Talmud Yerushalmi* (see below), and the Babylonian, correctly called *Talmud Babli*. The *Talmud Yerushalmi* embodies the discussions on the MISHNAH (*q.v.*) of hundreds of doctors, living in Palestine, chiefly in Galilee from the end of the 2d till about the middle of the 5th century, whilst the Babylonian Talmud embodies chiefly the discussions on the same *Mishnah* of hundreds of doctors living in various places in Babylonia, such as Neharde'a,[8] Kaphri,[9] Maḥuza,[10] Shekhanṣib,[11] but notably at the two great academies of Sura and Pumbaditha, from about 190 to nearly the end of the 6th century. The doctors of both recensions, although they primarily discuss the correctness of the text and meaning of the *Mishnah* and what should be the right legal decision according to it, do not confine themselves to this. They introduce, as occasion serves, not merely the whole of the oral tradition handed down to their time, and the necessary references to, and interpretations of, the various laws to be found in the Pentateuch and the other sacred writings, but exhibit also, though only in a fragmentary manner, an almost complete cycle of the profane sciences as current orally and known to them by books composed by Jews and Gentiles. The doctors of both these recensions were and are called *Amoraim* (אֲמוֹרָאִים), *i.e.*, mere "discussers, speakers,"[1] because, unlike the Mishnic doctors, who were and are called *Tannaim* (תַּנָּאִים), *i.e.*, "learners, teachers," they abstained from making new laws unless absolutely compelled by circumstances to do so.[2] These *Amoraim* stand, on the whole, in the same relation to their Mishnic predecessors as counsel giving a legal opinion, or judges deciding legal cases, stand to the legislature which frames the laws. In these points the doctors of both recensions agree. There are, however, also points of considerable difference between the two Talmuds. These are not merely geographical, and so necessarily linguistic,[3] but also material. Whilst the discussions in the Palestinian Talmud are simple, brief, and to the point, those in the Babylonian Talmud are subtle, long-winded, and, although always logical, sometimes even far-fetched.[4] But there is another difference. The Palestinian Talmud, besides containing legal and religious discussions, is a storehouse of history, geography, and archæology, whilst the Babylonian Talmud, taking into consideration that it is treble[5] the size of its fellow Talmud, contains less of these. On the other hand, it bestows more care upon the legal and religious points, and, being the later and the more studied of the two, it is also the more trustworthy.

---

[1] Compare *Mishnah, Peah*, i. 1, ותלמוד תורה כנגד כלם ("and the studying of the Law balances them all"); *Aboth*, iv. 13, זהיר בתלמוד הוי ("be circumspect as regards instruction").

[2] See Perek Rabbi Meir, 6, ולא מגיס לבו בתלמודו ("whose heart is not arrogant on account of his learning"); *cf.* T. B., *Pesaḥim*, leaf 49*a*; ותלמודו משתכח ממנו ("his learning becomes forgotten by him").

[3] See T. B., *Synhedrin*, leaf 24*a*, תלמודה של בבל ("the mode of study prevalent in Babylonia"); comp. T. B., *Pesaḥim*, 34*b*, טפשאי בבלאי דיתבי בארעא דחשוכא אמריתון שמעתתא דמחשכו כשום ("foolish Babylonians, who, because ye dwell in a land of darkness, say sayings that are obscure"), and T. B., *Baba Meṣi'a*, leaf 85*a*; Rabbi Zera fasted a hundred fasts on going up to Palestine, so that he might forget the style of Babylonico-Talmudic study (גמרא בבלאה or תלמודא בבלאה), that it should not trouble him any further. Rashi takes the quotation from *Baba Meṣi'a* to signify the concrete Babylonian Talmud, which, however, is impossible.

[4] See T. B., *Kiddushin*, leaf 40*b*: "Is theory (תלמוד) greater or practice (מעשה) greater? . . . They all answered, Theory (למוד) is greater because it leads to practice." *Talmud*, as will have been seen, is here given as synonymous with *Limmud*.

[5] See T. B., *Baba Ḳamma*, leaf 104*b*, יש תלמוד קאמינא ("I say this is a plain [Mosaic] teaching").

[6] See T. B., *Baba Bathra*, leaf 130*b*, catchword אין למדין, and *Variæ Lectiones in loco*.

[7] See T. B., *Baba Meṣi'a*, leaf 33*b*, and compare Rashi *in loco*.

[8] The rector of this academy was Shemuel, court physician of Shapur I., and astronomer. Whilst his friend and fellow pupil RAB (*q.v.*: they both attended the lectures of the principal editor of the *Mishnah*) excelled in the other parts of the Jewish law, Shemuel was pre-eminent in the civil law. On account of this he is repeatedly called in the Talmud both "Shapur" (like his master) and "Aryokh" (lion, king, teacher). To him is due the legal principle that "the law of the civil government is *the* law," *i.e.*, that except in religious matters the Jew must submit to the laws of his country (T. B., *Baba Bathra*, 54*b*). Shemuel and Rab (like Rabbi Yoḥanan and Resh Laḳish, Abayye and Raba, and others), though intimate friends, nevertheless differ on nearly all imaginable points, so that when the Talmud wishes to give firmness to a certain decision or opinion, it uses the phrase: "Rab and Shemuel, etc., both agree."

[9] The rector of this school was Rab Ḥisda, the father-in-law of RABA (*q.v.*).

[10] The rector of this school was RABA (*q.v.*).

[11] The rector of this school was Rab Maḥman b. Yiṣhaḳ (T. B., *Gittin*, 31*b*, Rashi, catchword אנא), husband of the learned and accomplished Yaltha, the daughter of the resh galutha (T. B., *Ḥullin*, leaf 109*b*), etc.

System of the Talmud.—Most people imagine not only that the Talmuds are a pathless wilderness, without so much as grammatical rules in their respective languages, but that the laws laid down in them rest on mere tradition. In reality their languages have strictly grammatical rules (see below under *Aids*, etc.), and their laws rest on a strictly logical system. The laws in both Talmuds are discussed and argued on philosophical rules, for which it is claimed that they have existed from time immemorial, and can be traced to the Pentateuch itself. These are—(1) the Seven Rules (שבע מדות), put forth by Hillel (*Tosephto Synhedrin*, vii., last §; *Siphro*, towards the end of the Introduction; *Aboth de-Rabbi Nathan*, xxxvii.) but a great deal older than his time; (2) the Thirteen Rules (שלש עשרה מדות), put forth by R. Yishma'el (Introduction to *Siphro*), which can, however, be traced *in nuce* to the foregoing "Seven Rules"; both these are for the *Halakhah*; and (3.) there are also the Thirty-two Rules (שלשים ושתים מדות), put forth by R. Eli'ezer b. R. Yose Haggalili (vol. i. of most editions of the Babylonian Talmud), which are for the *Agadah*. In addition, most of the points to which these rules apply are secured by early tradition. It is quite true that by idiosyncrasy digressions are very frequent both in Talmud and *Midrash*; but in the *Halakhah* the digression, however long, invariably ends in coming back to the original cause of the logical combination, whilst in the *Agadah* the digression either comes back to the place from which it started, or else will be found, on examination, to have been introduced for its own sake, and have served its own purpose. As the doctors of Talmud and *Midrash* are mostly introduced in dialogues, this is the only practical, if somewhat uncommon, method.

Division of the Talmud.—The external division of both Talmuds is identical with the division, subdivision, and sub-subdivision of the *Mishnah*, although there is not always *Gemara* in the one when there is *Gemara* in the other.[6] This, however, need not be further discussed here, as all on this head is minutely specified in MISHNAH (*q.v.*). Concerning the internal division into *Halakhah* and *Agadah*, it ought to be said that the former is more largely represented in the Babylonian Talmud, whilst the latter is more largely and more interestingly given in the Palestinian Talmud. Whole collections of *Midrashim* now in our hands have constituted (if we may judge from the known to the unknown) part of the Palestinian Talmud,[7] and seem to have chiefly belonged to those portions of it which have been gradually lost.

Purpose.—The Talmud, unlike the *Mishnah*, contains not only individual decisions, but everything that is necessary for arriving at legal and religious decisions of whatever description these may be, whilst, like the *Mishnah*, it is not itself a handbook of decisions. This is only in accordance with the nature and spirit of an oral law which delegates the decisions to the Talmudico-speculative capacities of the teachers of every age. Even several of the comparatively few instances in which the words . . . והלכתא כ׳ ("and the decision is according to so and so") occur in the Babylonian Talmud are a later addition. They belong to the *Halakhoth Gedoloth*,[8] and are consequently, at the earliest, of the 8th century, but are probably of even much later date.

Editors.—The editorship of the Palestinian Talmud is generally, after Maimonides,[9] ascribed to Rabbi Yoḥanan (b. Napḥa). But this, if literally taken, is a gross mistake, as that teacher (*ob.* 279) died more than a hundred years before the latest *Amora* (*c.* 450) mentioned in that Talmud. A similar error is made with respect to the editor or editors of the Babylonian Talmud, whose names are given as Rab Asshi (see RAB) (*ob.* 427) and Rabina (*ob.* 550), and who lived still much earlier than the last teachers mentioned in that Talmud (8th century). But it ought to be remembered that when the ancients speak of editors of books of such a mixed character as the *Mishnah*, the *Zohar*, both Talmuds, etc., they mean the person or persons who gave the first impulse to the collection or redaction of such books. In this sense, certainly, Rabbi Yoḥanan was the editor of the Palestinian and Rab Asshi and Rabina were the editors of the Babylonian Talmuds. For, whilst the first of the latter pair went more than once through the discussion of the whole *Mishnah* by the *Amoraim* from 190 to his time (*c.* 427), the latter supplemented the collection down to his own time (550). As regards the Babylonian Talmud, the *Amoraim* were succeeded by a new order of men called *Saboraim* (סבוראי רבנן), *i. e.*, "opiners," who ventured only occasionally to revise and authenticate the sayings of their predecessors. The last of these *Saboraim* were Rab 'Ina (or Giza) and Rab Simona (*c.* 550–590). In any case neither the one Talmud nor the other was written down, slight private notes excepted (מגלות סתרים), before the close of the 6th century, if then. The apparently insurmountable difficulty of keeping such vast masses of literature in the head is removed when one takes into consideration that both teacher and student had means of help to their memory fully corresponding to the vastness of the literature. In the first place, they had the *numbers* already occurring in the *Mishnah* (*e.g.*, *five* must not separate the heave-offering on account of the benediction to be recited in connection with the act; *Terumoth* i. 1), etc. Secondly, they had *names.* Since to the sayings of the Talmud were generally attached the names of those who uttered them, saying and name became in the memory of the student identical. If somebody who had heard a certain saying from somebody, who in his turn had heard it from somebody else, was mentioned in the Talmud, all other sayings, however unlike these in nature, if they had only the same link of tradition, were recited on the same occasion: *e.g.*, in the Palestinian Talmud, *Megillah* iv. 1, "says Rabbi Ḥaggai, says Rabbi Shemuel b. Rab Yiṣḥaḳ," etc.; T. B., *Berakhoth*, leaf 3*b*, etc., "says Rabbi Zeriḳa, says Rabbi Ammi, says Rabbi Yehoshua' b. Levi," etc. Thirdly, *other oral traditions*, which went by the order of the Pentateuch, received in the written Pentateuch vast aids to memory. Fourthly, the *Mishnah* (although itself not written down), by its divisions, subdivisions, and sub-subdivisions, became, in its turn, a mighty aid to memory. Fifthly, as regards the Babylonian Talmud, there are additional means of aiding memory in existence, for every now and then one meets with a *Mnemosynon* (*Siman*), which strings together the order of subjects (*e.g.*, T. B., *Berakhoth*, 32*a*, last line). Both in MSS. and printed editions these *Simanim* are given in brackets. Rapoport and his followers would have us believe that these mnemonic phrases are late inventions, but they have as yet failed to make good their assertions. See T. B., *Shabbath* 104*a*, and T. B., '*Erubin*, 54*b*, where these *Simanim* are positively mentioned early in the 4th century; *cf.* Rashi *in loco.*

---

[1] *Amora* may also mean an interpreter. The great teachers of the first five centuries had generally a man (or several men) at their side, who to the learning requisite to translate the master's teaching given in Hebrew, and dilate on it in Aramaic, added a Stentor's voice, and could by fascinating speech command the attention of the audience. The first Babylonian *Amora, i.e.*, explainer of the *Mishnah*, who had an *Amora, i.e.*, a popular teacher, was Rabbi Shila. The first who is known to have acted as *Amora, i.e.*, popular teacher, to an *Amora, i.e.*, an explainer of the *Mishnah*, was the famous RAB (*q.v.*). See T. Y., *Berakhoth*, iv. 1, 2, etc.: T. B., *Berakhoth*, leaf *27b*; and T. B., *Yoma*, leaf *20b* (against Rapoport, '*Erekh Millin*, s. v. "Amora").

[2] This certainly was not unfrequently the case, but even then they did so only in the spirit of the *Tannaim*.

[3] The Palestinian *Amoraim*, teaching people who understood Greek, had not to explain the Greek terms which frequently occur in the *Mishnah* and other works kindred to it. The Babylonian *Amoraim*, however, who in common with their hearers were ignorant of Greek, had a somewhat irregular though certainly effective way (received by them traditionally) of explaining the Greek terms in the *Mishnah*, etc., by Aramaic etymology. We will give two instances only of this practice: (1) אפותיקי, which is evidently the Greek ὑποθήκη, is explained T. B., *Baba Meṣi'a*, leaf *66b*, לא יהא לך פרעון אלא מזו, "thou shalt get no payment except from this,"—evidently = אפה תהא קאי = "upon this thou shalt stand," *i.e.*, "if I do not pay, this shall serve as my security"; compare Rashi on *Baba Ḳamma*, 11*b*, catchword אפותיקי; (2) דיתיקי is evidently the Greek διαθήκη, and is explained as being a compound of (קים) דא תהא למיקם, "this shall stand when I am no more," *i.e.*, "this is my last will and testament." From T. B., *Baba Bathra*, leaf 135*b* (evidently a Babylonian *Boroitho*), we see that in T. B., *Baba Meṣi'a*, leaf 19*a*, three words (כל שכתוב בה) have fallen out.

[4] Compare p. 40, footnote 3.

[5] Bibliographers generally fall into a mistake in describing the size of the Babylonian as twelve times that of the Palestinian Talmud. They forget that two-thirds of the size of the former is simply owing to the commentaries by which it is invariably accompanied.

[6] The only thing that ought to be mentioned here is, that to the Palestinian Talmud the *Sheba' Massekhloth Ḳetannoth Yerushalmiyyoth* (Frankfort, 1851, 8vo.) must be added, whilst *Gemara Shekalim* and the *Massekhtoth Ḳetannoth*, which now form an integral part of the Babylonian Talmud, are (*Aboth de-Rabbi Nathan* excepted) unjustifiably attached to it.

[7] See Rashi on Gen. xlvii. 2.

[8] *E.g.*, T. B., *Berakhoth*, leaf 36*a*. See Rashi and *Tosaphoth*, catchword והלכתא; *Ibid.*, 36*b*, and in other places.

[9] In his Introduction to the commentary on the *Mishnah* (commonly, but by mistake, called Introduction to the *Seder Zer'aim*) and in his Introduction to the *Mishneh Torah*.

Value.—The value of the Talmuds may be estimated by the fact that they contain the *Mishnah* in various recensions and a large portion of the contents of Midrashic collections, and in addition comprise a vast amount of Sopheric literature not to be found in the canonical *Mishnah* and Agadic matter not to be found in the known *Midrashim*, and have thousands of notices on secular knowledge of all kinds. Here, however, the reader ought to be again reminded that, whilst the Babylonian Talmud, the one of much larger extent, contains a great deal more Judæo-religious matter, the Palestinian Talmud—of much smaller extent—is of much greater value for the historian, the geographer, the numismatist, and other students.

Vicissitudes of the Talmud.—Whilst the Babylonian Talmud commanded the attention of a hostile world, and was proscribed, mutilated,[1] and condemned, and finally delivered over to the flames[2] by popes and kings, the Palestinian Talmud suffered still more from one single enemy—neglect.[3] Thousands of copies of the former recension were destroyed in the course of time, but, this Talmud being studied in all parts of the world, the few copies surviving became the means of an endless supply. Not so as regards the Palestinian Talmud, which found no students, or but few, after the closing (*c.* 450) of the Jewish academies in Palestine; and we have even to thank the enemies of traditional Judaism, the Ḳaraites, who used it in controversy with their Rabbanite opponents, for the preservation of some copies of it. By degrees the neglect of the book became so great that whole chapters of treatises, whole treatises of orders, and almost two whole orders themselves, disappeared, and are lost to this day.[4]

Aids to the Study of the Talmuds.—(*a*) *Lexicons.*—The first rank is occupied by lexicons for both Talmuds and *Midrashim*, and of these that by R. Nathan b. Yeḥiel of Rome, compiled in the 11th and 12th centuries, claims the first place. All other lexicons, from Elias Levita, Philip Aquinas, Johannes Buxtorf, etc., down to Levy and Jastrow, are more or less based upon this grand work called '*Arukh.*[5] (*b*)

---

[1] Raymundus Martin (Ramon Martinez), backed up by his teacher Pablo Cristiani (see RAMBAN), was one of the first five (or rather six) mutilators (called censors) of the Talmud and kindred books. See Touron, *Histoire des Hommes Illustres de l'Ordre de Saint Dominique*, i. (Paris, 1743, 4to.) p. 492; *Jour. Philol.*, xvi. 134.

[2] In the midsummer of 1244 twenty-four wagons full of Talmud copies were burned in France (see *Journal of Philology*, xvi. 133). A certain Donin (afterwards called Nicolaus), a converted Jew, by his accusations against the Talmud, managed that Rabbi Yeḥiel of Paris had to dispute with him publicly about its contents. The disputation took place in the midsummer of 1240; and R. Yeḥiel came out of it so victoriously that only after four years' further machinations the Talmud was actually burned. The disputation is printed under the name of *Disputatio cum Nicolao A.* 1252 (!) *habita cum Versione Latina* in Wagenseil's *Tela Ignea Satanæ* (Altdorf, 1681, 4to); a less incorrect Hebrew edition came out in 1873, 8vo, at Thorn. This event of burning the Talmud called forth three elegies—(1) by R. Binyamin b. Abraham De' Mansi, beginning אבות עולם, and the refrain of which was חכמה מפארה אי כשנה ונכלא אי (see MS. Add. 374, Camb. Univ. Lib., leaves 307*a*–308*a*); (2) by R. Meir of Rothenburg (see ROSH), the beginning of which is שאלי שרופה באש (in the Ashkenazic ritual for the 9th of Ab); and (3) by R. Abraham b. Yiṣḥaḳ (see Zunz, *Zur Gesch. u. Lit.*, pp. 463-4). This Abraham b. Yiṣḥaḳ is the father of the famous En-bonet Abram Bederesi (not Bedarshi; see Schiller-Szinessy, *Catal.*, i. correction 5), the author of the *Beḥinath 'Olam.*

[3] See Schiller-Szinessy in the *Academy*, 1878, p. 171, and extract from Excursus iii. (to the *Catalogue*) on the Palestinian Talmud in *Occasional Notices*, etc., i., Cambridge, 1878, 8vo.

[4] See the before-mentioned *Occasional Notices.*

[5] Rabbenu Nathan b. Yeḥiel b. Abraham was, on his father's side, an 'Anav (ענו)—and not an 'Akko (עכו) as Rapoport, no doubt after Ibn Yaḥya, writes it in *Bikkure Ha'ittim*, x. 7—*i.e.*, of the family 'Anavim (Dei Mansi, Dei Mansueti, Dei Piatelli, Dei Pietosi, Dei Umani, Dei Umili), and, on his mother's side, of the *Tappuḥim*, *i.e.*, De Pomis, to which the celebrated author of the Lexicon *Ṣemaḥ David* belonged. Rabbenu Nathan's father and grandfather, like Rabbenu Nathan himself and his brother's descendants, were, no doubt, papal court Jews (and not linendrapers, as the latest editor of the '*Arukh*, by misreading and misinterpreting the somewhat hard verses of his author, contrives to show). This lucrative position furnished them with ample means not only for their noble charities to congregational institutions (a synagogue, religious bath, etc.), but also with the leisure necessary for the pursuit of Talmudic studies. Rabbenu Nathan was *resh kallah* (rector of the Jewish university), and unquestionably the greatest Talmudist, even as he was the poorest Hebrew poet, in Italy in the 11th and 12th centuries. As regards his teachers we know four, three of whom he attended, whilst he studied and digested the works of the fourth so well that, though personally unknown to one another, they may be justly called master and disciple. His first teacher was his own father; his second teacher, from whom Rabbenu Nathan no doubt obtained his thorough knowledge of Babylonian habits, was R. Maṣliaḥ of Sicily, who had been a hearer of the greatest "gaon" of Pumbaditha; his third teacher was R. Mosheh b. Ya'aḳob b. Mosheh b. Abbun of Narbonne (or Toulouse; better known under the name of R. Mosheh Haddarshan); and the fourth was Rabbenu Ḥananeel of Kairwan. He owed so much to this teacher that as soon as the '*Arukh* had appeared most people took it for granted that Rabbenu Ḥananeel had lived at Rome, and accordingly called him "a man of Rome—'Ish Romi;" see MS. Brit. Mus. Add. 27,201, leaf 73*b*, and *Tosaphoth*, *passim.* (That Rabbenu Gershom, Rabbenu Mosheh נפוסי, and others were his teachers, as Rapoport, *loc. cit.*, asserts, is a fiction.) Rabbenu Nathan, in his '*Arukh*, does not merely explain the foreign (*i.e.*, Aramaic, Persian, Greek, Latin, and Arabic), words occurring in the Targums, Talmuds, and *Midrashim*, but the subject-matter also, and thereby proves himself a doubly useful guide. In this, although he had been preceded by no less a personage than the *Gaon* Ṣemaḥ b. Paltoi (fl. 870), who also composed such an '*Arukh*, Rabbenu Nathan was virtually the first, as the *Gaon's* work had been early lost. The assertion that the fourth of the four men captured by the Spanish admiral (see below, p. 43) was R. Nathan Habbabli, that he lived in Narbonne, and that he also composed a similar '*Arukh*, rests on a misunderstanding, as the quotation in the *Yoḥasin* clearly shows. The passages there given under R. Nathan Habbabli are taken *verbatim* from the '*Arukh* of our author (compare the article שנש, etc.). That Rome has been at times called in Jewish writings "Babel," and that consequently *Habbabli* may mean "the Roman," is clear from the writings of the New Testament. We will only add here a few words concerning the bibliography of the book. Of the '*Arukh* exist so far ten editions, the first of which came out undated, but before or about 1480. The seventh edition was enriched by the physician R. Binyamin Musaphia's *Musaph*, *i.e.*, *Additamenta* (Musaphia was a Greek and Latin

Grammars.—A slight attempt at compiling a grammar, and this only for the Babylonian Talmud, was made by the late learned S. D. Luzzatto. It exists in Italian (Padua, 1865), German by Krüger (Breslau, 1873), English by Goldammer (New York, 1876), and Hebrew by Lerner (St. Petersburg, 1880). Of more value, however, is Nöldeke's *Mandaitic Grammar*, although it stands in connection with the Babylonian Talmud only in an indirect way. (*c*) *Commentaries.*—Commentaries on the greater portion of the Babylonian Talmud are extant, by the famous Rabbenu Ḥananeel of Kairwan, the teacher of RIPH (*q.v.*), by RASHI (*q.v.*), and by the descendants and disciples of this latter commentator, who composed the *Tosaphoth*. All these are included in the latest Talmud edition of Vilna. It is asserted by RABAD II. (*q.v.*) that the whole (B.) Talmud had been commented on in Arabic. As regards the commentaries on the Palestinian Talmud, it ought to be said that the *Pene Mosheh*, etc., by R. Mosheh Margaliyyoth, and the *Ḳorban Ha'edah*, etc., by R. David Fränkel (the teacher of Mendelssohn), make more than one commentary on the whole, and they are embodied in the Zhitomir edition (1860–67). (*d*) *Methodology.*—Among the many Introductions to the Babylonian Talmud that of R. Shemuel Hannagid must now be considered the first, not only in time, but also in value. There was indeed an earlier, and perhaps a still more valuable one in existence (see SAADIA), but it is now unfortunately lost. As regards the Palestinian Talmud, the only one in existence is that by the late Z. Frankel (Breslau, 1870, 8vo). The author was a most learned man, but somewhat confused in his diction. (*e*) *Translations.*—Renderings of isolated treatises of the Babylonian Talmud exist in Latin, Ugolini, *Thesaurus*, xix., *Zebaḥim* and *Menaḥoth*, and xxv., *Synhedrin*;[1] in French, *e.g.*, *Berakhoth*, by Chiarini (Leipsic 1831, 8vo); and in German, *e.g.*, *Berakhoth*, by Rabe (Halle, 1777, 4to.), regard being had also in both to the same treatise of the Palestinian recension, and again by Pinner (1842); *Baba Meṣi'a*, by Sammter (1876), both at Berlin and in folio; *'Abodah Zarah*, by Ewald (Nuremberg, 1856, 8vo); *Ta'anith*, by Straschun (Halle, 1883); *Megillah* and *Rosh Hasshanah*, by Rawicz (Frankfort-on-the-Main, 1884 and 1886). The assertion that the whole of this Talmud has been translated into Spanish has yet to be proved. As regards the Palestinian Talmud, Ugolini's *Thesaurus* contains the following treatises in Latin: *Pesaḥim* (vol. xvii.); *Sheḳalim, Yoma, Sukkah, Rosh Hasshanah, Ta'anith, Megillah, Ḥagigah, Beṣah, Mo'ed Katan* (vol. xviii.); *Ma'aseroth, Ma'aser Sheni, Ḥallah, 'Orlah, Bikkurim* (vol. xx.); *Synhedrin, Makkoth* (vol. xxv.); *Ḳiddushin, Sotah, Kethuboth* (vol. xxx.). M. Schwab (of the Bibliothèque Nationale, Paris) has undertaken a French translation of the entire Palestinian Talmud, which is now in progress; from this *Berakhoth* has been translated into English (London, 1886, 4to.).

Editions.—The editions of the Palestinian Talmud, in what was then called its entirety, are only four:—(*a*) Venice, 1523, without any commentary; (*b*) Cracow, 1609, with a short commentary, the text apparently from a different MS. from that used for the *editio princeps*; (*c*) Krotoschin, 1866, with a short commentary differing from that of Cracow: these three editions are each comprised in one volume; (*d*) the fourth edition came out at Zhitomir, with commentaries by different men (see *Commentaries* above). All these editions are in folio. Of the editions of isolated treatises, which are not a few, we will only mention those of *Berakhoth* (Vienna, 1874) and *Peah* and *Demai* (Breslau, 1875, both in 4to.), with a new commentary by Z. Frankel. The editions of the Babylonian Talmud are so numerous that they would require several entire sheets for enumeration. There is in existence an approximately good treatise on them (see *Variæ Lectiones*, vols. i. and viii.). We will only name three of the entire editions: (1) the *editio princeps*, Venice, 1520–23,[2]—which, though disfigured by numerous misprints, was not mutilated by the censor; (2) the edition of Basel (1578–81), which omits *'Abodah Zarah* altogether, and has a cheering (?) notice in Latin;[3] (3) the latest edition, now printing at Vilna, with old commentaries hitherto unpublished. Of isolated treatises, which may be counted by more than hundreds, we will only mention one (the Portuguese of at least *Berakhoth*), the existence of which was asserted in the last century (*Paḥad Yiṣḥaḳ*, s. v. ננבא במחתרתא), then again called in question in our own times, but positively proved by the present writer from an early work composed at the time when but few editions of the Talmud existed. It is the *Zera' Abraham* (Camb. MS. Ti. 6. 50, leaf 59*b*). Materials for the critical edition of the Babylonian Talmud from an ancient MS. formerly in the monastery of Pfersee, but now in the Royal Library of Munich, and other MSS. and early prints of isolated treatises in various public and private libraries of Europe, Asia, and Africa, have been collected and are being published by Rabbinovicz. Of this important work fifteen volumes, containing the following treatises, have already come out: the whole *Seder Zera'im* (1867); *Beṣah, Ḥagigah, Mo'ed Ḳatan* (1869); *Sukkah, Ta'anith* (1870); *Rosh Hasshanah, Yoma* (1871); *'Erubin* (1873); *Pesaḥim* (1874); *Shabbath* (1875); *Megillah, Sheḳalim* (1877); *Synhedrin* (1878); *'Abodah Zarah, Makkoth, Shebu'oth, Horayoth, 'Eduyyoth* (1879); *Baba Bathra* (1881); *Baba Ḳamma* (1882); *Baba Meṣi'a* (1883); *Zebaḥim* (1884); *Menaḥoth* (1886).[4] All these were printed in 8vo. and at Munich, except vol. ix., which came out at Mainz.

Influence of the Talmud.—It must be admitted by every critical student of history that the Talmud has not merely been the means of keeping alive the religious idea among the Jews, but has formed their strongest bond of union. When, after the fall of the city of Jerusalem and its temple, and the expatriation of the Jews from Palestine, a goodly portion of the Mosaic law lost its application, the Talmud became the spirit which put fresh life into the letter which had become to a great extent dead. Moreover, by the Talmud, the interpretation of which was chiefly in the hands of the academies of Sura and Pumbaditha, the Jews of all the world found, if not a new Jerusalem, at least a new Yabneh (Jamnia), *i.e.*, a place where the old learning was not merely continued, but made to shine with a yet greater splendor. This fact will be the more readily acknowledged and appreciated when one casts a glance at the miserable religious condition of the Ḳaraites, the so-called Scriptural Jews.

Transference of Talmudic Learning from the East to the West.—There naturally came a time when Talmudic learning, if it was to maintain its influence upon the Jews, could not be confined to one spot. We have seen under RASHI (*q.v.*) that the great emperor of the West (Charlemagne) had been the means, towards the close of the 8th century, of bringing learned Talmudists not only to Provence but to the north of France and the south of Germany.[5] But when nearly two hundred years later the academies of Babylonia were threatened with extinction (because of their lacking, from various causes, the means of subsistence), so that they had to send out members of their body to supplicate the support of their richer brethren in other countries, it providentially happened that the four men whom they sent were taken by a Spanish corsair admiral and sold in four different slave-markets. Rabbi Shemaryah was sold at Alexandria, and was redeemed by the Jews, and great was their astonishment when they recognized in him a most able Talmudist. He became the head of the Cairo community, and one of the most successful Jewish Talmud teachers Egypt ever had. Rabbi Ḥusshiel was taken to Kairwan, in Africa. There the Jews redeemed him; and when his great learning was found out he was named the spiritual head of the Jews in that place. From the

---

scholar), and the latest edition by Dr. Kohut is now in progress. As regards the MSS. of this remarkable lexicon the best copies are to be found partly in the University Library, Cambridge (Add. 376, which has all the verses of the author and *additamenta* by R. Shemuel Ibn גָּנע, and Add. 471–72), and partly at the Court Library, Vienna (Cod. cvi. 1 and 2). The latter were carried off by Napoleon I. to Paris in 1809, but in 1815 were returned to Vienna.

[1] Various writers assert that there exist many books containing Latin translations of various treatises of the Babylonian Talmud. Upon examination these books turn out to contain either a translation only of Mishnic treatises with or without excerpta from, and with or without scholia on, *Gemara*, or disputations which introduce small pieces of *Gemara*. The utmost they contain is a chapter or two translated from *Gemara* itself (as, for example, "Edzard, Aboda Sara," etc., Hamburg, 1705–10, 4to, which contains *Gemara* of the first two *Peraḳim*).

[2] The paging of this has been followed in all subsequent editions.

[3] Nunc ab omnibus iis quæ contra religionem Christianam faciebant recognitum, et juxta mentem Sacri concilii Tridentini expurgatum et approbatum, ut non modo citra impietatem verum etiam cum fructu a nostris legi possit.

[4] The notes in the first fourteen volumes go under the name of דברי כופרים, whilst those of the fifteenth volume have the title of זכור לאברהם, in memory of the late Abraham Merzbacher, who not merely proved the Mæcenas of this publication during his lifetime, but left a considerable sum for its continuation and completion.

[5] Italy, notably Sicily, was apparently the country which obtained her teachers direct from Iraḳ.

school which he founded sprang not merely his own son, the famous Rabbenu Ḥananeel, but also the great Rabbenu Nissim, both teachers of RIPH (*q. v.*). Another learned captive. R. Mosheh, was brought to the slave-market of Cordova, the rabbi of which town, a noble and rare example of unselfishness, modesty, and love of truth, placed the ragged stranger who had only been ransomed for charity's sake a day or so before at the head of the community instead of himself. The name of the fourth is unknown (see RABAD II., and *Yohasin*, ed. Cracow, leaf 125*b*). Some assert that he was R. Nathan Habbabli, and that he became the teacher of the Jews in Narbonne, but this is a mere conjecture, the truth of which has yet to be proved (see page 43, footnote[7]). Be this, however, as it may, four great Talmudists, who had come direct from the Babylonian academies, became the means of bringing Babylonico-Talmudic learning to places the Jews of which had been dependent on the religious and literary crumbs that fell from the richly-laden tables of Sura and Pumbaditha. Some years afterwards the former academy was closed, and a short time afterwards the same fate befell that of Pumbaditha, the sunset of which, if not the noonlight, in the persons of Rab Sherira Gaon and his son Rab Haï Gaon was even more glorious than that of the sister academy, the last "gaon" of which was Rab Shemuel b. Ḥophni, father-in-law of Rabbenu Haï. Meanwhile, however, Talmudic learning had not merely become naturalized, but eventually indigenous in various parts of Africa, and part of Europe (Spain, Italy, Provence, the south of Germany, and the north of France). Rabbenu Gershom b. Yehudah of Metz and his disciple Rabbenu Yiṣḥaḳ of Troyes, Rabbenu Ya‘aḳob b. Yaḳar of Worms, Rabbenu Eli‘ezer Haggadol and his disciple and successor Rabbenu Yiṣḥaḳ Segan Leviyyah, Rabbenu Yiṣḥaḳ b. Yehudah of Mainz, Rabbenu Elyaḳim of Spires, Rabbenu Nathan b. Yeḥiel of Rome, and last but not least Rashi himself, and his sons-in-law and other disciples, represented Talmudic learning in such perfection as had not been found before as regards the Babylonian Talmud, even in the land of its birth and growth. It was the disciples' disciples of these men who studied and taught in various towns of England within a hundred years (1150) after the Conquest. When, towards the end of the 13th century and the commencement of the 14th, the Jews were driven out of England (1290) and France (1306), and flocked chiefly to Italy, Greece, Germany, and Poland, the last-named country appropriated the lion's share of Talmudic learning, so that till within our own century the rabbis of the chief communities in Hungary, Moravia, Bohemia, and other Austrian states, and in Germany, Holland, England, etc., had to be fetched from Poland. Talmudic learning, since Mendelssohn and his school arose, threatened to die out not merely among the Jews in Germany, but also among those of the other countries where the Jews spoke the German tongue in some form or other. Within the last twenty-five years, however, fresh impulse has been given to these studies, not merely among Jews but also among Christians.

(S. M. S.-S.)

TAM, commonly called RABBENU TAM, more correctly RABBENU THAM (רַבֵּנוּ תָּם — ר״ת). By this title are known two eminent Rabbinic scholars, both named YA‘AḲOB, to whom this epithet was given in allusion to Genesis xxv. 27: "And Jacob was a *perfect* man" (*Ish Tam*, אִישׁ תָּם). They belonged to the north of France, lived in the 12th century, and were master and pupil.

1. RABBENU YA‘AḲOB B. MEIR B. SHEMUEL was, on his mother's side, a grandson of RASHI (*q.v.*). He was his parents' third son, younger brother of Ribam and RASHBAM (*q.v.*), older brother of Rabbenu Shelomoh of Rameru,[1] and brother-in-law of Rabbenu Shemuel b. Simḥah of Vitry the younger[2] (the reputed author of the *Maḥzor Vitry*,[3] now apparently lost)[4]. Rabbenu Tham had, like his grandfather Rashi, six teachers: (1) his own father, (2) his brother Ribam, (3) his brother Rashbam, (4) Rabbenu Ya‘aḳob b. Shimshon,[5] (5) his grandfather Rashi,[6] and (6) Rabbenu Yoseph Tob-‘Elem the younger.[7] Rabbenu Tham had at least five children.[8] The names of three of his sons were Yoseph,[9] Yiṣḥaḳ,[10] and Shelomoh.[11] Rabbenu Tham was unquestionably among Jews the foremost man of his age. For not only was he the greatest Talmudist after his maternal grandfather's death, but he also added reading wide and varied to a stupendous memory and a marvellous power of combination, such as appeared only again in the last century in the persons of R. Yehonathan Eybenschütz (*ob.* 1764) and R. Yeḥezkel Landau (*ob.* 1793). Let us add that he was a lexicographer, grammarian, and Biblical commentator of no mean order; that he was a poet in Hebrew and Aramaic[12] inferior only to Ibn Gebirol (AVICEBRON, *q.v.*), Mosheh Ibn ‘Ezra, and Yehudah Hallevi (and by far greater in this art than the commentator Abraham Ibn ‘Ezra); that he was held in high esteem by prince and nobles;[13] and that he was a man of great wealth, with which he generously supported, not merely his own poorer hearers, but other itinerant scholars also.[14]

His works are the following:

(1) Commentary on Job, and, no doubt, on other parts of the Bible (see Camb. Univ. Lib. MS. Dd. 8. 53, leaves 1*b*, 4*a*, 11*a*, 12*b*). All these are apparently now lost. (2) *Hakhra‘oth*, *i.e.*, lexical and grammatical decisions between Menaḥem Ibn Seruḳ and Dunash b. Labrat (see *Sepher Teshuboth Dunash b. Labrat*, Edinburgh, 1885, 8vo.). That these "decisions" are really by Rabbenu Tham is proved by the before-named MS., leaves 10*a* and 16*a*, where the book is quoted by an author of the 13th century. (3) *Sepher Hayyashar* (Vienna, 1810, folio). Although this work, in its present form, is the compilation of one of Rabbenu Tham's disciples, R. Yiṣḥaḳ b. Durbal by name (also called Isaac of Russia; see Schiller-Szinessy, *Catalogue*, i. p. 164, and ii. p. 66), not only is the foundation Rabbenu Tham's (see Preface), but the contents also are virtually his. Compare the Cambridge MS. Add. 667. 1, *passim*. (4) The greater part of the *Tosaphoth* in the Babylonian Talmud are indirectly also by Rabbenu Tham; and he is virtually the first Tosaphist. It is true that his father, his brother RASHBAM (*q.v.*), and his uncle Rabbenu Yehudah b. Nathan had written *Tosaphoth* before him, and that this kind of literary activity lasted to within the first

[4] See art. RASHI (vol. xx. p. 296, note 10).

[5] This rabbi was a disciple of R. Shemuel Hallevi (see Schiller-Szinessy, *Catal.*, ii. p. 65, note 1) and of Rashi, and was not only a great Talmudist, as were all the disciples of the last-named eminent teacher, but also a great mathematician and astronomer, though a terribly bad poet. His commentary on *Aboth* is in part printed, and is to be found, more or less perfect, in various libraries in Europe, although not recognized as his. It is ascribed variously to Rashi, to Rashbam, and others. There are copies of it in Cambridge (Add. 1213; Add. 1523) Oxford (Opp. 317), the British Museum (Add. 27,201), the Beth Hammidrash of the Ashkenazim in London, etc. (The master of St. John's, Cambridge, is preparing an edition of it.) A work on intercalation by Rabbenu Ya‘aḳob b. Shimshon exists in MS. at the Bodleian (Opp. 317) under the name of *Sepher Haelḳoshi*. From him, no doubt, Rabbenu Tham imbibed his love for science. On the fact that Rabbenu Ya‘aḳob b. Shimshon was Rabbenu Tham's teacher (against Zunz), see Schiller-Szinessy, *Catal.*, ii. p. 66, note.

[6] Rabbenu Tham, dying an old man, must have been from fourteen to sixteen years of age when Rashi died.

[10] See *Sepher Hayyashar*, § 604.

[11] See *Shibbole Halleḳet* (ed. Buber), p. 10.

[12] See his *Yeẓib Pithgam* (in the Ashkenazic ritual; it is introductory to the prophetic lesson for the second day of Pentecost. If we have the correct reading of that poem there, Rabbenu Tham must have been a Levite; and if so, the Shemuel Hallevi mentioned by R. Ya‘aḳob b. Shimshon as his teacher, in the Cambridge MS. Add. 1213, leaf 27*b*, is very possibly Rabbenu Tham's paternal grandfather.

[13] See *Sepher Hayyashar*, § 595 (leaf 67*a*, col. 1), and § 610 (1st) *in fine*. To this high position it is no doubt to be ascribed that his life was saved by a knight during the second crusade, in which the whole congregation of Rameru was reduced to beggary, after many of its members had been ruthlessly slain.

[14] For example, the poverty-stricken Abraham Ibn ‘Ezra, to whom he not only gave money but kind words also, in good verses (*Kerem Ḥemed*, vii. p. 35).

quarter of the 14th century. Still, most and the best of the *Tosaphoth* now in our hands rest on Rabbenu Tham and his school. (5) *Mahzor, i.e.*, a prayer-book, etc., for the whole year, with Rabbinic ordinances, etc. See *Tosaphoth* on T. B., *Berakhoth*, leaf 37*a*, catchword הכוכס, and *Birekhoth Maharam* of R. Meir b. Barukh of Rothenburg (Riva di Trento, 1558, 8vo.), leaf 4*a*. (6) Poems. These are partly didactic and partly liturgical. Of the former kind a specimen will be found ("On the Accents," communicated by Halberstam) in Kobak's *Yeshurun*, v. p. 125 *sq.* The liturgical poems, again, are of two kinds: (*a*) such as have no metre and rhyme only by means of plurals, possessive pronouns, and such like (rhymed prose), and which perfectly resemble most of the productions of the Franco-Ashkenazic school (see, for example, the facsimile in Muller's *Catalogue*, Amsterdam, 1868, 8vo); (*b*) such as have metre and rhyme, and resemble the productions of the Sepharadic school, *e.g.*, the one beginning "י׳ בך כ׳ע׳נ׳" (and not בו; see MS. Add. 667, leaf 102*a*).[1] (7) Various ordinances, etc., are to be found in later writers (see MS. Add. 667, in Cambridge, *passim*, and *Teshuboth Maharam*, Prague, 1608, folio, ֹ 1023, etc.). Rabbenu Tham died in 1171; see Rashi's *Siddur*, ii. (formerly Luzzatto's, then Halberstam's, and now the property of the master of St. John's College, Cambridge), leaf 48*a*.

2. **Rabbenu Ya'aḳob** of Orleans, rabbi of London (?). He is often quoted in the *Tosaphoth* (both on the Pentateuch and on the Babylonian Talmud). No independent works of his, however, are extant. He was killed at London in the tumult on the coronation day of Richard Cœur-de-Lion (September 3, 1189; Schiller-Szinessy, *Catal.*, i. p. 117). (S. M. S.-S.)

TAMAQUA, a borough of Schuylkill county, Pennsylvania, United States, in a broken, hilly country upon the Little Schuylkill river, 98 miles nearly north of Philadelphia. It is in the midst of the anthracite coal region, and coal mining is one of its principal interests. It is an important railroad centre, upon the Philadelphia and Reading system, being the point of intersection of three main lines and the terminus of several minor branches. The borough had a population of 5960 in 1870 and of 5730 in 1880.

TAMARIND. This name is popularly applied to the pods of a Leguminous tree, which are hard externally, but within filled with an acid juicy pulp containing sugar and various acids, such as citric and tartaric, in combination with potash. The acid pulp is used as a laxative and a refrigerant, the pods being largely imported both from the East and the West Indies. The tree is now widely distributed in tropical countries, but it is generally considered that its native country is in eastern tropical Africa, from Abyssinia southward to the Zambesi. Sir Ferdinand von Mueller notes that it is truly wild in tropical Australia. The name (meaning in Arabic "Indian date") shows that it entered mediæval commerce from India, where it is used, not only for its pulp, but for its seeds, which are astringent, its leaves, which furnish a yellow or a red dye, and its timber. The tree (*Tamarindus indica*, L.) attains a height of 70 to 80 feet, and bears elegant pinnate foliage and purplish or orange veined flowers arranged in terminal clusters. The flower-tube bears at its summit four sepals, but only three petals and three perfect stamens, with indications of six others. The stamens, with the stalked ovary, are curved away from the petals at their base, but are directed towards them at their apices. The anthers and the stigmas are thus brought into such a position as to obstruct the passage of an insect attracted by the brilliantly-colored petal, the inference of course being that insects are necessary for the fertilization of the flower.

TAMARÍSK. The genus *Tamarix* gives its name to a small group of shrubs or low trees constituting the tamarisk family. The species of tamarisk and of the very closely allied genus *Myricaria* grow in salt deserts, by the sea-shore, or in other more or less sterile localities in south temperate, sub-tropical, and tropical regions of the eastern hemisphere. Their long slender branches bear very numerous small appressed leaves, in which the evaporating surface is reduced to a minimum. The flowers are minute and numerous, in long clusters at the ends of the branches or from the trunk. Each has 4–6 free sepals, and as many petals springing with the 4–12 stamens from a fleshy disk. In *Tamarix* the stamens are free, while in *Myricaria* they are united into one parcel. The free ovary is one-celled, with basal placentas, and surmounted by 3–5 styles. The fruit is capsular, and contains numerous seeds, each usually with a long tuft of hairs at one end. The great value of these shrubs or trees lies in their ability to withstand the effects of drought and a saline soil, in consequence of which they grow where little else can flourish. It is on this account that the common tamarisk, *T. Gallica*, is planted on our sea-coasts, and affords shelter where none other could be provided. The light feathery appearance of the branches, and the pretty rose-colored flowers, render it also an elegant and attractive shrub, very different in character from most others.

Some species produce galls, valued for their tannin, while the astringent bark of others has been valued for medicinal purposes. The ashes of the plant, when grown near the sea, are said to contain soda; but, when cultivated inland or on sweet soil, they are, it is alleged, free from soda.

For tamarisk manna, see **Manna**, vol. xv. p. 500.

TAMBOFF, one of the largest and most fertile governments of central Russia, extends from north to south between the basins of the Oka and the Don, and has Vladimir and Nijni-Novgorod on the N., Penza and Saratoff on the E., the Don Cossacks and Voronezh on the S., Tula and Ryazañ on the W. It consists of an undulating plain intersected by deep ravines and broad valleys, ranging between 450 and 800 feet above sea-level. Chalk and Jurassic deposits, thickly covered by boulder-clay and loess, are widely spread over its surface, concealing the underlying Devonian and Carboniferous deposits. These last appear only in the deeper ravines, and seams of coal have been noticed at several places. Iron ore (in the northwest), limestone, clay, and gypsum are obtained for building and manufacturing purposes; traces of naphtha have been discovered at Tamboff. The mineral waters of Lipetsk, similar to those of Franzensbad in their alkaline elements, and chalybeate like those of Pyrmont and Spa, are well known in Russia. Tamboff is watered by the tributaries of the Oka and the Don. The Oka itself only touches the northwest corner of the government; but its tributaries, the Moksha and the Tsna, are important channels of traffic. The Don also only touches Tamboff, and of its affluents only the Voronezh and the Khoper and its tributary the Vorona are at all navigable. As a whole, it is only in the north that Tamboff is well watered; in its southern part, which is exposed to the influence of the dry southeastern winds, the want of moisture is much felt, especially in the district of Borisoglyebsk, which belongs to the dry steppes of the lower Volga.

The climate is continental, and, although the average temperature at Tamboff is 42° F., the winter is comparatively cold (January, 13°; July, 68°). The rivers remain frozen for four months and a half. Forests occupy less than one-sixth of the total area, and occur chiefly in the west; in the southeast wood is scarce, and straw is resorted to for fuel. The soil is fertile throughout; in the north, indeed, it is clayey and sometimes sandy, but the rest of the government is covered with a sheet, 2 to 3 feet in thickness, of the most fertile *tchernozem*, of such richness, indeed, that in Borisoglyebsk corn-fields which have not been manured for eighty years still yield good crops.

Tamboff is one of the densely peopled provinces of Russia. Its population in 1883 reached 2,519,660, and in several districts (Kozloff, Lebedyañ, Lipetsk) there are from 110 to 130 inhabitants per square mile. It is Great Russian in the central portion, but has a notable admixture of **Mordvinians** (*q.v.*) and Mescheriaks in the west and northwest, as also of Tartars: the Mordvinians (who are rapidly becoming Russified) constitute 4 per cent. of the aggregate population of Tamboff; the Tartars number about 20,000, and the Mescheriaks about 4000. Nonconformity is widely spread, although the official figures disclose only 14,300 Raskolniks. Notwithstanding a high birth-rate (45 in the thousand), the annual increase of population is but slow (0.5 per cent. annually).

---

[1] For other metrical poems by Rabbenu Tham, see Zunz, *Literaturg. der Syn. Poesie* (Berlin, 1865, 8vo), p. 266.

The prevailing occupation is agriculture, and in 1883 only 168,200 persons had their residence in towns, which are mostly themselves nothing but large villages of agriculturists living together with a few merchants. More than two-thirds of the area is arable, and of this proportion 53 per cent. belongs to peasant communities, 36 per cent. to private individuals, and 11 per cent. to the crown. The crops of the years 1883 to 1885 yielded on the average 8,885,000 quarters of grain (half being rye, and one-third oats). Corn is exported to a considerable extent from the south, although it is deficient in the north. Hemp and linseed are also cultivated for exportation. The cultivation of tobacco is yearly increasing; 5220 acres were under this crop in 1885, and yielded nearly 50,000 cwts. In the same year 15,950 acres were under beetroot, and yielded 1,660,000 cwts. Cattle-breeding, though less extensively carried on than formerly, is still important (656,300 horses; 399,500 horned cattle, and 1,326,600 sheep in 1883). Excellent breeds of horses are met with, not only on the larger estates, but also in the hands of the wealthier peasants, those of the Bityug river being most esteemed. Manufactures are represented chiefly by distilleries, tallow-melting works, sugar-works, and a few wollen-cloth mills. The petty trades are not very extensively carried on in the villages. Commerce is very brisk, owing to the large amounts of corn exported,—Kozloff, Morshansk, Tamboff, and Borisoglyebsk being the chief centres for this traffic, and Lebedyañ for the trade in horses and cattle. Tamboff is rather backward educationally: in 1883 there were only 629 schools, attended by 34,739 boys and 5680 girls. The government is divided into twelve districts, the chief towns of which, with their populations in 1884, are Tamboff (34,000 inhabitants), Borisoglyebsk (13,000), Elatma, (7560), Kirsanoff (7770), Kozloff (27,900), Lebedyañ (6250), Lipetsk (15,860), Morshansk (21,200), Shatsk (7260), Spassk (5010), Temnikoff (13,700), and Usmañ (8110 in 1880). A distinctive feature of Tamboff is its very large villages of crown-peasants, a dozen of which have from 5000 to 7000 inhabitants each. Several of them—like Raskazovo (a great centre of Nonconformity), Ałabukhi, Sasovo, Izberdei, and Arkhangelskoye—are important commercial centres.

The region now included in the north of the government was settled by Russians during the earliest centuries of the principality of Moscow, but until the end of the 17th century the fertile tracts to the south remained too insecure for settlers. In the following century a few immigrants began to come in from the steppe, and landowners who had received large grants of land as gifts of the czars began to bring their serfs from central Russia. The population has very rapidly increased within the present century.

TAMBOFF, capital of the above government, 300 miles distant from Moscow, is situated on the Tsna river, and on the railway from Kozloff to Saratoff. It is almost entirely built of wood, with broad unpaved streets, lined with low houses surrounded by gardens. It has a small public library, a theatre, and the few educational institutions which are usual in the chief towns of Russian provinces. Its manufactures are insignificant; and its trade, in local grain and in cattle purchased in the south and sent to Moscow, is far less important than that of Morshansk or Kozloff. The population in 1884 was 34,000.

TAMERLANE. See TIMUR.

TAMILS. The word *Tamil* (properly *Tamil̤*) has been identified with Draviḍa, the Sanskrit generic appellation for the South Indian peoples and their languages; and the various stages through which the word has passed—Dramiḍa, Dramila, Damila—have been finally discussed by Bishop Caldwell in his *Comparative Grammar of the Dravidian Languages* (2d ed., 1875, p. 10 *sq.*), and the derivation has recently been endorsed by Col. Yule and Dr. Burnell in their *Glossary* (p. 251*b*). The identification was first suggested by Dr. Graul (*Reise nach Ostindien*, vol. iii., 1854, p. 349), and then adverted to by Dr. G. U. Pope (*Tamil Handbook*, 1859, Introduction) and Dr. Gundert (*Malayâḷma Dictionary*, 1872, *s.v.*). It should, however, be mentioned that the former prefers now to take the word Tamil̤ to be a corruption of *tenmol̤i*, southern speech, in contradistinction to *vaḍugu*, the northern, *i.e.*, Telugu language. As in the case of the Kafir, Turkish, Tagala, and other typical languages, the term Tamulic or Tamulian has occasionally been employed as the designation of the whole class of Dravidian peoples and languages, of which it is only the most prominent member. The present article deals with Tamil in its restricted sense only.

The Tamils, taken as the type and representatives of the Dravidian race, do not now, owing to early intermixture with the Aryan immigrants, materially differ in physical character from the other curly-haired indigenous population of India. They were at one time, on the ground of the general structure of their language, classed with the Mongoloid (Turanian, Scythian) and even the Australian races, but that classification is rejected by all the leading ethnologists. They form in fact, with the other members of the group, a separate and distinct family, which is of the dolichocephalic class, and comes near the Indo-European or Aryan type; while there are scattered remnants of a still earlier population of India (Mundas, Kolarians), whose race characteristics, however, do not so essentially differ from those of the Dravidians as to constitute them a class by themselves. The Tamils proper are smaller and weaker-built than the Europeans, though more graceful in shape. Their physical appearance is described as follows: a pointed and frequently hooked pyramidal nose, with conspicuous nares, more long than round; a marked sinking in of the orbital line, producing a strongly defined orbital ridge; hair and eyes black; the latter, varying from small to middle-sized, have a peculiar sparkle and a look of calculation; mouth large, lips thick and frequently turgid; lower jaw not heavy, its lateral expansion greater than in the Aryan and less than in the Turanian type, giving to the middle part of the face a marked development and breadth, and to the general contour an obtuse oval shape, somewhat bulging at the sides; forehead well-formed, but receding, inclining to flattish, and seldom high; occiput somewhat projecting; beard considerable, and often strong; color of skin very dark, frequently approaching to black (*Manual of the Administration of the Madras Presidency*, Madras, 1885, vol. i., Introd., p. 36; see also Caldwell, *Comparative Grammar of the Dravidian Languages*, 1875, pp. 558–79). The Tamils have many estimable qualities,—frugality, patience, endurance, politeness,—and they are credited with astounding memories; their worst vices are said to be lying and lasciviousness. Of all the South-India tribes they are the least sedentary and the most enterprising. Wherever money is to be earned, there will Tamils be found, either as merchants or in the lower capacity of domestic servants and laborers. The tea and coffee districts of Ceylon are peopled by about 800,000; Tamils serve as coolies in the Mauritius and the West Indies. In Burmah, the Straits, and Siam the so-called Klings are all Tamils (Graul, *Reise nach Ostindien*, Leipsic, 1855, vol. iv. pp. 113–212).

Language.—The area over which Tamil is spoken extends from a few miles north of the city of Madras to the extreme south of the eastern side of the peninsula, throughout the country below the Gháts, from Pulicat to Cape Comorin, and from the Gháts to the Bay of Bengal, including also the southern portion of Travancore on the western side of the Gháts and the northern part of Ceylon. According to the census of 1881, the number of Tamil-speaking people throughout the province was 12,413,517, inclusive of 21,992 Yerkalas, 3843 Kurumbas, and 287 Irulas, three tribes speaking rude dialects of the language. To these should be added about 160,000 in the French possessions. But, as of all the Dravidian languages the Tamil shows the greatest tendency to spread, its area becomes ever larger, encroaching on that of the contiguous languages. Tamil is a sister of Malayâḷma, Telugu, Canarese, Tulu, Kuḍagu, Toda, Kôta, Gôṇḍ, Khond (Ku), Urâon, Râjmahâl, Keikâdi, and Brahuî, the nine last-named being uncultivated tongues; and, as it is the oldest, richest, and most highly organized of the Dravidian languages, it may be looked upon as typical of the family to which it belongs. The one nearest akin to it is Malayâḻma, which originally appears to have been simply a dialect of Tamil, but differs from it now both in pronunciation and in idiom, in the retention of old-Tamil forms obsolete in the modern language, and in having discarded all personal terminations in the verb, the person being always indicated by the pronoun (F. W. Ellis, *Dissertation on the Malayâḻma Language*, p. 2; Gundert, *Malayâḻma Dictionary*, Introd.; Caldwell, *Comparative Gr.*, Introd., p. 23; Burnell, *Specimens of South Indian Dialects*, No. 2, p. 13). Also, the proportion of Sanskrit words in Malayâḻma is greater, while in Tamil it is less, than in any other Dravidian tongue. This divergence between the two languages cannot be traced farther back than about the 10th century; for, as it appears from the Cochin and Travancore inscriptions, previous to that period both languages were still substantially identical; whereas in the *Râmacharitam*, the oldest poem in Malayâḻma, composed probably in the 13th century, at any rate long before the arrival of the Portuguese and the introduction of the modern character, we see that language already formed. The modern Tamil *characters* originated "in a Brahmanical adaptation of the old Grantha letters corresponding to the so-called Vaṭṭeḻuttu," or round-hand, an alphabet once in vogue throughout the whole of the Pândyan kingdom, as well as in the South Malabar and Coimbatore districts, and still sparsely used for drawing up conveyances and other legal instruments (F. W. Ellis, *Dissertation*, p. 3). It is also used by the Mâppilas in Tellicherry. The origin of the Vaṭṭeḻuttu itself is still a controverted question. The late Dr. Burnell, the greatest authority on the subject, has stated his reasons for tracing that character through the Pehlevi to a Semitic source (*Elements of South Indian Palæography*, 2d ed., 1878, pp. 47–52, and plates xvii. and xxxii.). In the 8th century the Vaṭṭeḻuttu existed side by side and together with the Grantha, an ancient alphabet still used throughout the Tamil country in writing Sanskrit. During the four or five centuries after the conquest of Madura by the Cholas in the 11th it was gradually superseded in the Tamil country by the modern Tamil, while in Malabar it continued in general use down to the end of the 17th century. But the earliest works of Tamil literature, such as the *Tolkâppiyam* and the *Kuraḷ*, were still written in it. The modern Tamil characters, which have but little changed for the last 500 years, differ from all the other modern Dravidian alphabets both in shape and in their phonetic value. Their angular form is said to be due to the widespread practice of writing with the style resting on the *end* of the left thumb-nail, while the other alphabets are written with the style resting on the left side of the thumb.

The Tamil alphabet is sufficiently well adapted for the expression of the twelve vowels of the language (*a, â, i, î, u, û, e, ê, o, ô, ei, au*),—the occasional sounds of *ö* and *ü*, both short and long, being covered by the signs for *e, ê, i, î*; but it is utterly inadequate for the proper expression of the consonants, inasmuch as the one character *k* has to do duty also for *kh, g, gh*, and similarly each of the other surd consonants *ch, ṭ, t, p*, represents also the remaining three letters of its respective class. The letter *k* has, besides, occasionally the sound of *h* and *ch* that of *s*. Each of the five consonants *k, ch, ṭ, t, p* has its own nasal. In addition to the four semivowels, the Tamil possesses a cerebral *ṛ* and *ḷ*, and has, in common with the Malayâḻma, retained a liquid *ḻ*, once peculiar to all the Dravidian languages, the sound of which is so difficult to fix graphically, and varies so much in different districts, that it has been rendered in a dozen different ways (*Manual of the Administration of the Madras Presidency*, vol. ii. p. 20 *sq.*). Fr. Müller is probably correct in approximating it to that of the Bohemian *ř*. There is, lastly, a peculiar *n*, differing in function but not in pronunciation from the dental *n*. The three sibilants and *ḥ* of Sanskrit have no place in the Tamil alphabet; but *ch* often does duty as a sibilant in writing foreign words, and the four corresponding letters as well as *j* and *ksh* of the Grantha alphabet are now frequently called to aid. It is obvious that many of the Sanskrit words imported into Tamil at various periods (Caldwell, *loc. cit.*, Introd., pp 86 *sq.*) have, in consequence of the incongruity of the Sanskrit and Tamil notation of their respective phonetic systems, assumed disguises under which the original is scarcely recognizable: examples are *ulagu* (loka), *uruvam* (rûpa), *arukken* (arka), *aṛputam* (adbhutam), *naṭchattiram* (nakshatram), *iruḍi* (ṛishi), *tîrkam* (dîrgha), *arasen* (râjan). Besides the Sanskrit ingredients, which appear but sparsely in the old poetry, Tamil has borrowed from Hindustani, Arabic, and Persian a large number of revenue, political, and judicial terms, and more recently a good many English words have crept in, such as *tiraṭṭi*, treaty, *paṭlar*, butler, *âkṭ*, act, *kulôb*, club, *kavarnar*, governor, *pinnalkôḍu*, penal code, *sîkku*, sick, *mejastiraṭṭu*, magistrate. But, as compared with its literary sister languages, it has preserved its Dravidian character singularly free from foreign influence. Of Tamil words which have found a permanent home in English may be mentioned curry (*kaṛi*), mulligatawny (*milagu*, pepper, and *taṇṇîr*, cool water), cheroot (*suruttu*), pariah (*paṛeiyan*).

The laws of euphony (avoiding of hiatus, softening of initial consonants, contact of final with initial consonants) are far more complicated in Tamil than in Sanskrit. But, while they were rigidly adhered to in the old poetical language (Sen-Tamiḻ), there is a growing tendency to neglect them in the language of the present day (Koḍun-Tamiḻ). It is true the Tamil rules totally differ from the prevailing Sanskrit; still the probability is in favor of a Sanskrit influence, inasmuch as they appear to follow Sanskrit models. Thus, *iruḷ nîkkinân* becomes *iruṇîkkinân; pon pâttiram, poṛpâttiram; vûṭṭil kaṇḍên, vûṭṭiṛ-kaṇḍên; vâlsiṛumei, vâṭsiṛumei; palan tandân, palanṛundân.* Nouns are divided into high-caste or personal and low-caste or impersonal,—the former comprising words for rational beings, the latter all the rest. Only in high-caste nouns a distinction between masculine and feminine is observed in the singular; both have a common plural, which is indicated by change of a final *n* (feminine *l*) into *r;* but the neuter plural termination *kal* (*gal*) may be superadded in every case. Certain nouns change their base termination before receiving the case affixes, the latter being the same both for singular and plural. They are for the acc. *ei*, instr. *âl*, social *ôḍu* (*oḍu*, *uḍan*), dat. *ku*, loc. *il* (*iḍattil*, *in*), abl. *ilirundu* (*ininṛu*), gen. *uḍeiya* (*adu*). There is, besides, a general oblique affix *in*, which is not only frequently used for the genitive, but may be inserted before any of the above affixes, to some of which the emphatic particle *ê* may also be superadded. In the old poetry there is a still greater variety of affixes, while there is an option of dispensing with all. Adjectives, when attributive, precede the noun and are unchangeable; when predicative they follow it and receive verbal affixes. The pronouns of the 1st person are sing. *nân* (*yân*), inflectional base *en*, plural *nâm* (*yâm*), infl. *nam*, including *nângaḷ*, infl. *engaḷ*, excluding the person addressed; of the 2d person *nî*, infl. *un* (*nin, nun*), plural *nîr* (*nîyir, nîvir*), *nîngaḷ*, infl. *um*, *ungal* (*num*). To each of those forms, inclusive also of the reflexive pronouns *tân, tâm, tângaḷ*, a place is assigned in the scale of honorific pronouns. As in the demonstrative pronouns the forms beginning with *i* indicate nearness, those with *a* distance, and (in the old poetry) those with *u* what is between the two, so the same forms beginning with *e* (or *yâ*, as in *yâr*, *âr*, who?) express the interrogative. The verb consists of three elements—the root (generally reducible to one syllable), the tense characteristic, and the personal affix. There are three original moods, the indicative, imperative, and infinitive (the 2d singular imperative is generally identical with the root), as well as three original tenses, the present, past, and future. The personal affixes are—sing. (1) *-ên;* (2) *-ây*, honorific *-îr;* (3) masc. *-ân*, fem. *-âḷ*, honor. *-âr*, neuter *-adu;* plural (1) *-ôm* (*-âm*, *-êm*); (2) *-îrkaḷ;* (3) masc. fem. *-ârkaḷ*, neut. *-ana*. These affixes serve for all verbs and for each of the three tenses, except that, in the future, *-adu* and *-ana* are replaced by *-um* (*kkum*). It is only in the formation of the tenses that verbs differ, intransitive verbs generally indicating the present by *-kiṛ-* (*-kinṛ-*), the past by *-d-*, *-nd-*, or *-in-*, and the future by *-v-* (*-b-*), and transitive verbs by the corresponding infixes, *-kkiṛ-* (*-kkinṛ-*), *-tt-* (*-nd-*), and *-pp-;* but there are numerous exceptions and seemingly anomalous formations. Other tenses and moods are expressed with the aid of special affixes or auxiliary verbs. Causal verbs are formed by various infixes (*-ppi-*, *-vi-*, *-ttu-*), and the passive by the auxiliary *paḍu*, to fall, or by *uṇ*, to eat, with a noun. The following four peculiarities are characteristic of Tamil: first, the tenseless negative form of the verb, expressed by the infix *a*, which is elided before dissimilar vowels; second, the predicative employment of two negative particles *illei* and *alla*, the one denying the existence or presence, the other denying the quality or essence; third, the use of two sets of participles,—one, called adjective or relative participle, which supplies the place of a relative clause, the language possessing no relative pronouns, and an ordinary adverbial participle or gerund; and, fourth, the practice of giving adjectives a verbal form by means of personal affixes, which form may again be treated as a noun by attaching to it the declensional terminations, thus: *periya*, great; *periyóm*, we are great; *periyómukku*, to us who are great. The old poetry abounds in verbal forms now obsolete. Adjectives, adverbs, and abstract nouns are derived from verbs by certain affixes. All post-positions were originally either nouns or verbal forms. *Oratio indirecta* is unknown in Tamil, as it is in all the other Indian languages, the gerund *enṛu* being used, like *iti* in Sanskrit, to indicate quotations. The structure of sentences is an exact counterpart of the structure of words, inasmuch as that which qualifies always precedes that which is qualified. Thus the attributive precedes the substantive, the substantive precedes the preposition, the adverb precedes the verb, the secondary clause the primary one, and the verb closes the sentence. The sentence, "Having called the woman who had killed the child, he asked why she had committed such infanticide," runs in Tamil as follows:

Kuḷandeiyei kkonṛupottavaḷei aleippittu
The child her who had killed having caused to be called,
nî ên ippadi ppaṭṭa sisu-v-atti seydây ênṛu
"Thou why thus made child-murder didst?" having said
kêṭṭân..
he asked.

Much as the similarity of the structure of the Tamil and its sister languages to that of the Ugro-Tartar class may have proved suggestive of the assumption of a family affinity between the two classes, such an affinity, if it exist, must be held to be at least very distant, inasmuch as the assumption receives but the faintest shade of support from an intercomparison of the radical and least variable portion of the respective languages.

Literature.—The early existence, in southern India, of peoples, localities, animals, and products, the names of which, as mentioned in the Old Testament and in Greek and Roman writers, have been identified with corresponding Dravidian terms goes far to prove the high antiquity, if not of the Tamil language, at least of some form of Dravidian speech (Caldwell, *loc. cit.*, Introd., pp. 81–106; *Madras District Manual*, i., Introd., p. 134 *sq.*). But practically the earliest extant records of the Tamil language do not ascend higher than the middle of the 8th century of the Christian era, the grant in possession of the Israelites at Cochin being assigned by the late Dr. Burnell to about 750 A.D., a period when Malayâḷma did not exist yet as a separate language. There is every probability that about the same time a number of Tamil works sprung up, which are mentioned by a writer in the 11th century as representing the old literature (Burnell, *loc. cit.*, p. 127, note). The earlier of these may have been Saiva books; the more prominent of the others were decidedly Jaina. Though traces of a North-Indian influence are palpable in all of them that have come down to us (see, *e.g.*, F. W. Ellis's notes to the *Kuṛaḷ*), we can at the same time perceive, as we must certainly appreciate, the desire of the authors to oppose the influence of Brahmanical writings, and create a literature that should rival Sanskrit books and appeal to the sentiments of the people at large. But the refinement of the poetical language, as adapted to the genius of Tamil, has been carried to greater excess than in Sanskrit; and this artificial character of the so-called High-Tamil is evident from a comparison with the old inscriptions, which are a reflex of the language of the people, and clearly show that Tamil has not undergone any essential change these 800 years (Burnell, *loc. cit.*, p. 142). The rules of High-Tamil appear to have been fixed at a very early date. The *Tolkâppiyam*, the oldest extant Tamil grammar, is assigned by Dr. Burnell (*On the Aindra School of Sanskrit Grammarians*, pp. 8, 55) to the 8th century (best edition by C. Y. Tâmodaram Pillei, Madras, 1885). The *Vîrasôḻiyam*, another grammar, is of the 11th century. Both have been superseded by the *Nannûl*, of the 15th century, which has exercised the skill of numerous commentators, and continues to be the leading native authority (English editions in Pope's *Third Tamil Grammar*, and an abridgment by Lazarus, 1884). The period of the prevalence of the Jainas in the Pâṇḍya kingdom, from the 9th or 10th to the 13th century, is justly termed the Augustan age of Tamil literature. To its earlier days is assigned the *Nâlaḍiyâr*, an ethical poem on the three objects of existence, which is supposed to have preceded the *Kuṛaḷ* of Tiruvaḷḷuvan, the finest poetical production in the whole range of Tamil composition. Tradition, in keeping with the spirit of antagonism to Brahmanical influence, says that its author was a pariah priest. It consists of 1330 stanzas on virtue, wealth, and pleasure. It has often been edited, translated, and commented upon; see the introduction to the excellent edition, just published, by the Rev. Dr. Pope, in which also a comprehensive account of the peculiarities of High-Tamil will be found. To the Avvei, or Matron, a reputed sister of Tiruvaḷḷuvan, but probably of a later date, two shorter moral poems, called *Attisûḍi* and *Konṛeivêyndan*, are ascribed, which are still read in all Tamil schools. *Chintâmaṇi*, an epic of upwards of 3000 stanzas, which celebrates the exploits of a King Jîvakan, also belongs to that early Jain period, and so does the *Divâkaram*, the oldest dictionary of classical Tamil. The former is one of the finest poems in the language; but no more than the first and part of the third of its thirteen books have been edited and translated. Kamban's *Râmâyaṇam* (about 1100 A.D.) is the only other Tamil epic which comes up to the *Chintâmaṇi* in poetical beauty. The most brilliant of the poetical productions which appeared in the period of the Saiva revival (13th and 14th centuries) are two collections of hymns addressed to Siva, the one called *Tiruvâsakam*, by Mâṇikka-Vâsakan, and a later and larger one called *Têvâram*, by Sambandhan and two other devotees, Sundaran and Appan. Both these collections have been printed, the former in one, and the latter in five volumes. They are rivalled both in religious fervor and in poetical merit by a contemporaneous collection of Vaishṇava hymns, the *Nâlâyira-prabandham* (also printed at Madras). The third section of it, called *Tiruvâymoḻi*, or "Words of the Sacred Mouth," has lately been published in Telugu characters, with ample commentaries, in ten quartos (Madras, 1875–76). After a period of literary torpor, which lasted nearly two centuries, King Vallabha Deva, better known by his assumed name, Ativîrarâma Pâṇḍiyan (second half of the 16th century), endeavored to revive the love of poetry by compositions of his own, the most celebrated of which are the *Neiḍadam*, a somewhat extravagant imitation of Srî Harsha's Sanskrit *Naishadham*, and the *Veṛṛivêṛkei*, a collection of sententious maxims. Though he had numerous followers, who made this revival the most prolific in the whole history of Tamil literature, none of the compositions of every kind, mainly translations and bombastic imitations of Sanskrit models, have attained to any fame. An exceptional place, however, is occupied by certain Tamil sectarians called *śittar* (*i.e.*, *siddhas* or sages), whose mystical poems, especially those contained in the *Sivavâkyam*, are said to be of singular beauty. Two poems of high merit, composed at the end of the 17th century, also deserve favorable notice—the *Nîtineriviḷakkam*, an ethical treatise by Kumâragurupara Desikan, and the *Prabhulingalîlei*, a translation from the Canarese of a famous text-book of the Vîra Saiva sect. See the analysis in W. Taylor's *Catalogue*, vol. ii. p. 837–47.

The modern period, which may be said to date from the beginning of the last century, is ushered in by two great poets, one native and the other foreign. Tâyumânavan, a philosopher of the pantheistic school, composed 1453 stanzas (*pâdal*) which have a high reputation for sublimity both of sentiment and style; and the Italian Jesuit Joseph Beschi

(d. 1742), under the name Vîramâmuni, elaborated, on the model of the *Chintâmaṇi*, a religious epic *Têmbâvaṇi*, which, though marred by blemishes of taste, is classed by native critics among the best productions of their literature. It treats of the history of St. Joseph, and has been printed at Pondicherry in three volumes, with a full analysis. English influence has here, as in Bengal and elsewhere in India, greatly tended to create a healthier tone in literature both as to style and sentiment. As one of the best Tamil translations of English books in respect of diction and idiom may be mentioned the *Bâlavyâpârikaḷ*, or "Little Merchants," published by the Vernacular Text Society, Madras. P. Percival's collection of *Tamil Proverbs* (3d ed., 1875) should also be mentioned. The copper-plate grants, commonly called *śâsanams*, and stone inscriptions in Tamil, many of which have been copied and translated (*Archæological Survey of Southern India*, vol. iv.; R. Sewell, *Lists of the Antiquarian Remains in the Presidency of Madras*, vols. i., ii.), are the only authentic historical records. (See also Sir Walter Elliot's contribution to the *International Numismata Orientalia*, vol. iii. pt. 2.) As early as the time of the Chinese traveller Hwen Tsang, books were written in southern India on talipot leaves, and Albiruni mentions this custom as quite prevalent in his time (1031). It has not died out even at the present day, though paper imported from Portugal has, during the last three centuries, occasionally been used. Madras is now the largest depository of Tamil palm-leaf MSS., which have been described in Wilson's *Catalogue of the Mackenzie Collection* (Calcutta, 1828, 2 vols.), W. Taylor's *Catalogue* (Madras, 1857, 3 vols.), and Condaswamy Iyer's *Catalogue* (vol. i., Madras, 1861). The art of printing, however, which was introduced in southern India at an early date, while it has tended to the preservation of many valuable productions of the ancient literature, has also been the means of perpetuating and circulating a deal of literary rubbish and lasciviousness which would much better have remained in the comparatively safe obscurity of manuscript. Dr. Burnell has a note in his *Elements of South Indian Paleography* (2d ed., p. 44), from which it appears that in 1578 Tamil types were cut by Father João de Faria, and that a hundred years later a Tamil and Portuguese dictionary was published at Ambalakkâḍu. At present the number of Tamil books (inclusive of newspapers) printed annually far exceeds that of the other Dravidian vernaculars put together. The earliest Tamil version of the New Testament was commenced by the Dutch in Ceylon in 1688; Fabricius's translation appeared at Tranquebar in 1715. Since then many new translations of the whole Bible have been printed, and some of them have passed through several editions. The German missionary B. Ziegenbalg was the first to make the study of Tamil possible in Europe by the publication of his *Grammatica Damulica*, which appeared at Halle in 1716. Some time later the Jesuit father Beschi devoted much time and labor to the composition of grammars both of the vulgar and the poetical dialects. The former is treated in his *Grammatica Latino-Tamulica*, which was written in 1728, but was not printed till eleven years later (Tranquebar, 1739). It was twice reprinted, and two English translations have been published (1831, 1848). His *Sen-Tamil Grammar*, accessible since 1822 in an English translation by Dr. Babington, was printed from his own MS. (*Clavis humaniorum litterarum sublimioris Tamulici idiomatis*) at Tranquebar in 1878. This work is especially valuable, as the greater portion of it consists of a learned and exhaustive treatise on Tamil prosody and rhetoric. (See, on his other works, Graul's *Reise*, vol. iv. p. 327.) There are also grammars by Anderson, Rhenius, Graul (in vol. ii. of his *Bibliotheca Tamulica*, Leipsic, 1855), Lazarus, (Madras, 1878), Pope (4th edition in three parts, London, 1883-5), and *Grammaire Française-Tamoule*, by the Abbé Dupuis, Pondicherri, 1863. The last two are by far the best. The India Office library possesses a MS. dictionary and grammar "par le Rev. Père Dominique" (Pondicherri, 1843), and a copy of a MS. Tamil-Latin dictionary by the celebrated missionary, Schwarz, in which 9000 words are explained. About the like number of words are given in the dictionary of Fabricius and Breithaupt (Madras, 1779 and 1809). Rottler's dictionary, the publication of which was commenced in 1834, is a far more ambitious work. But neither it nor Winslow's (1862) come up to the standard of Tamil scholarship; the *Dictionnaire Tamoul-Français*, which appeared at Pondicherri in 2 vols. (1855–62), is superior to both, just as the *Dictionarium Latino-Gallico-Tamulicum* (*ibid.*, 1846), excels the various English-Tamil dictionaries which have been published at Madras.

TAMWORTH, a municipal borough and market-town of England, on the borders of Staffordshire and Warwickshire, chiefly in the former, is situated at the junction of the Tame with the Anker, and on branches of the London and North-Western and Midland Railway lines, 7 miles southeast of Lichfield, 20 northwest of Coventry, and 110 northwest of London. The castle, situated on a height above the Anker near its junction with the Tame, is now chiefly of the Jacobean period, but is enclosed by massive ancient walls. It was long the residence of the Saxon kings, and, after being bestowed on the Marmions by William the Conqueror, remained for many years an important fortress. Through the female line of the Marmions it has descended to the Marquis Townshend. Formerly the town was surrounded by a ditch called the King's Dyke, of which some trace still remains. The church of St. Editha, originally founded in the 8th century, was rebuilt, after being burned by the Danes, by Edgar, who made it collegiate, but the present building in the Decorated style was erected after a fire in the 14th century. Since 1870 it has been undergoing restoration at a cost of £10,000 [$48,600]. The free grammar school, refounded by Edward VI., was rebuilt in 1677, and again in 1867–68, at a cost of £3000 [$14,580]. The other public buildings are the swimming bath and boys' institute (1885), the town-hall (1701), and the arcade, formerly used as a covered market, but recently obtained by the Salvation Army. The charities include Guy's almshouses, endowed in 1678 by Thomas Guy, founder of Guy's Hospital, London, and the cottage hospital with twenty-one beds. Waterworks have recently been erected at a cost of over £25,000 [$121,500]. On the "moors" burgesses have rights for cattle. Coal, fireclay, and blue and red brick clay are dug in the neighborhood; and there are also market gardens. The town possesses a clothing factory, paper-mills, and manufactories of small wares. The population of the municipal borough (area 200 acres), in 1871 was 4589, and in 1881 it was 4891,—that of the parliamentary borough (area 11,602 acres) in the same years being 11,493 and 14,101. Tamworth ceased to be a parliamentary borough in 1885.

Tamworth is situated near the old Roman Watling Street, and occupies the site of a fort which, from the beginning of the 8th century, was the chief royal residence in Mercia. The town, after being burnt by the Danes, was rebuilt and fortified by Ethelfleda, daughter of Alfred the Great. From the reign of Edward the Martyr to that of William Rufus it was a royal mint, and some of the coins struck at Tamworth are still in existence. The town was incorporated in the 3d year of Elizabeth, from whom it obtained the grant of a fair and the confirmation of various privileges bestowed by Edward III. The Elizabethan charter was superseded by one conferred by Charles II., which continued to be the governing charter of the town till the passing of the Municipal Act. The town, with occasional intermissions, returned members to parliament from the reign of Henry I. till 1885. Among its more distinguished representatives have been Thomas Guy and Sir Robert Peel.

TANAGER, a word adapted from the quasi-Latin *Tanagra* of Linnæus, which again is an adaptation, perhaps with a classical allusion, of *Tangara*, used by Brisson and Buffon, and said by Marcgrave (*Hist. Rer. Nat. Brasiliæ*, p. 214) to be the Brazilian name of certain birds found in that country. From them it has since been extended to a great many others mostly belonging to the southern portion of the New World, now recognized by ornithologists as forming a distinct Family of *Oscines*, and usually considered to be allied to the *Fringillidæ* (*cf.* FINCH, vol. ix. p. 167); but, as may be inferred from Prof. Parker's remarks in the Zoological *Transactions* (x. pp. 252, 253, and 267), the *Tanagridæ* are a "feebler" form, and thereby bear

Müller, *Grundriss der Sprachwissenschaft*, Vienna, 1884, iii. i. 162–246. (R. R.)

out the opinion based on the examination of many types both of Birds and Mammals as to the lower morphological rank of the Neotropical Fauna as a whole (*cf.* BIRDS, vol. iii. p. 644).

The Tanagers are a group in which Mr. Sclater has for many years interested himself, and his latest treatment of them is contained in the British Museum *Catalogue* (xi. pp. 49–307). Therein he admits the existence of 375 species, which he arranges in 59 genera, forming six Subfamilies, *Procniatinæ*, *Euphoniinæ*, *Tanagrinæ*, *Lamprotinæ*, *Phœnicophilinæ*, and *Pitylinæ*. These are of very unequal extent, for, while the first of them consists of but a single species, *Procnias tersa*,—the position of which may be for several reasons still open to doubt,—the third includes more than 200. Nearly all are birds of small size, the largest barely exceeding a Song-Thrush. Most of them are remarkable for their gaudy coloring, and this is especially the case in those forming the genus called by Mr. Sclater, as by most other authors, *Calliste*, a term inadmissible through preoccupation, to which the name of *Tanagra* of right seems to belong, while that which he names *Tanagra* should probably be known as *Thraupis*. The whole Family is almost confined to the Neotropical Region, and there are several forms peculiar to the Antilles; but not a tenth of the species reach even southern Mexico, and not a dozen appear in the northern part of that country. Of the genus *Pyranga*, which has the most northern range of all, three if not four species are common summer immigrants to some part or other of the United States, and two of them, *P. rubra* and *P. æstiva*,—there known respectively as the Scarlet Tanager and the Summer Redbird,—reach even the Dominion of Canada, visiting as well, though accidentally, Bermuda. *P. æstiva* has a western representative, *P. cooperi*, which by some authors is not recognized as a distinct species. The males of all these are clad in glowing red, *P. rubra* having, however, the wings and tail black. The remaining species, *P. ludoviciana*, the males of which are mostly yellow and black, with the head only red, does not appear eastward of the Missouri plains, and has not so northerly a range. Another species, *P. hepatica*, has just shown itself within the limits of the United States. In all these the females are plainly attired; but generally among the Tanagers, however bright may be their coloration, both sexes are nearly alike in plumage. Little has been recorded of the habits of the species of Central or South America, but those of the north have been as closely observed as the rather retiring nature of the birds renders possible, and it is known that insects, especially in the larval condition, and berries afford the greater part of their food. They have a pleasing song, and build a shallow nest, in which the eggs, generally 3 in number and of a greenish-blue marked with brown and purple, are laid.

On a whole the *Tanagridæ* may perhaps be considered to hold the same relation to the *Fringillidæ* as the *Icteridæ* do to the *Sturnidæ* and the *Mniotiltidæ* to the *Sylviidæ* or *Turdidæ*, in each case the purely New-World Family being the "feebler" type.

TANCRED, one of the last Norman kings of Sicily, reigned 1189–1194. See SICILY, vol. xxii. p. 31.

TANGANYIKA, a lake in East Central Africa, called *Msaga* ("tempestuous") by the Wakawendi and *Kimana* by the Warungu. The meaning of the name Tanganyika is, according to Cameron, nothing more than "the mixing place." It is the longest freshwater lake in the world, being about 75 miles longer than Lake Michigan. Although the Arabs had long known of the existence of the lake, the first Europeans who discovered it were Speke and Burton in 1858. It has since been visited by Livingstone, Cameron, Stanley, Thomson, and Hore, who have all added to our knowledge of it. Tanganyika, which is situated some 600 miles as the crow flies from the east coast of Africa, extends from 3°-16′ S. lat. to 8° 48′ S. lat., and lies between 29° 10′ E. long. and 32° 30′ E. long. Its length is 420 miles, and its breadth varies from 10 to 50 miles. Its area is 12,650 square miles, and its altitude may be taken as 2700 feet above sea-level (Cameron 2710; Stanley, 2770; Hore, 2750; Popelin, 2665). It has a coast-line of 900 miles in extent. Its greatest depth has not yet been determined, but Hore states that a 168-fathom rope often failed to reach the bottom. Tanganyika may be described as an enormous crevasse. It is bordered on all sides by hills and mountains, some of which rise to from 5000 to 10,000 feet above its waters. The scenery is marked by exceptional grandeur, and is well calculated to impress the traveller. Burton says:

> "It filled us with admiration, with wonder, and delight. Beyond the short foreground of rugged and precipitous hill-fold, down which the footpath painfully zigzags, a narrow plot of emerald green shelves gently towards a ribbon of glistening yellow sand, here bordered by sedgy rushes, there clear and cleanly cut by the breaking wavelets. Farther in front stretches an expanse of the lightest, softest blue, from 30 to 35 miles in breadth, and sprinkled by the east wind with crescents of snowy foam. It is bounded on the other side by tall and broken walls of purple hill, flecked and capped with pearly mist, or standing sharply pencilled against the azure sky. To the south lie high bluff headlands and capes; and as the eye dilates it falls on little outlying islets, speckling a sea horizon. Villages, cultivated lands, the frequent canoes of the fishermen, give a something of life, of variety, of movement to the scenery."

Tanganyika is fed by numerous rivers and streamlets which flow from the surrounding hills, the yearly rainfall being about 27 inches, but the rainy seasons vary extremely in different years, altering the surface area of the lake accordingly. Hore found that between March, 1879, and August, 1880, the waters had fallen 10 feet 4½ inches, as marked by a water-gauge he had erected at Ujiji, and he also saw evident signs of the receding of the waters all round the shores of the lake—belts of dead timber and bleached rock. Some 120 rivers and streams flow into the lake; the most important river is the Malagarasi, near Ujiji. Just below the rapids its width is 500 feet, and the average depth 5 feet. For many years Tanganyika was a riddle to African explorers,—Livingstone, Baker, and others believing that it belonged to the Nile system, and that it was connected with the Albert Nyanza. That this theory is incorrect was proved when Livingstone and Stanley explored the north end of the lake in November, 1871, finding no outlet. It was Cameron, in March, 1874, who first solved the riddle, and found that the outlet of Tanganyika was the river Lukuga, at about the centre of the western shore of the lake, 5° 52′ 45″ S. lat. In 1876 this outlet was visited by Stanley, who found that there was no apparent outflow, and doubt was thrown upon Cameron's observations, which, however, have been proved to be correct by Hore, who in 1880 found a strong current setting unequivocally out of the lake. Not only so, but he obtained good views of the river, which gradually widens soon after the rapids near the lake are passed. He followed the river to 5° 50′ S. lat., and, from an altitude of 1100 feet above the river, he saw it flowing far away to the westward. The question is therefore settled that Lake Tanganyika belongs to the Congo system, but it is only an occasional tributary to that mighty river, its contribution depending upon the rainfall. The lake is subject to frequent storms, especially from the S.S.E. and S.W., lasting sometimes for two or three days, and leaving a heavy swell, which proves a great hindrance to navigation. Hore says: "I have never witnessed such wondrous cloud-scenery and majestic effects of thunder and lightning as on Tanganyika."

The shores and water of the lake abound in animal life,—crocodiles, the hippopotamus, otters, and many kinds of fish being found in its waters. Flocks of waterfowl abound in the river mouths: gulls, divers, herons, kingfishers, eagles, fish-hawks, and black ibis are very numerous. The shores are very fertile,—rice, manioc, kaffre corn, two kinds of ground-nuts, maize, uleysi, pumpkins, sweet potatoes, sugar-cane, castor-oil tree, tamarind, cotton, tomato, and cucumber growing luxuriantly. The oil palm grows at Ujiji, Urundi, and at the south end of the lake, the borassus near the Malagarasi river, the screw palm in Uguha, and the raphra in several localities. The tzetse fly is found on the shores of the lake from Ujiji round the southern end as far as Ubwari on the west coast. Amongst the useful timber trees may be noticed the gigantic mbule, the mininga, lignum vitæ, and ebony. The people inhabiting the countries on the borders of the lake form ten distinct tribes, with separate national peculiarities and customs. They live in well-organized villages, in which considerable social order is maintained. They have also learnt, to some extent at any rate, to utilize the products of their country; they work their own iron and copper; salt is prepared for barter; palm oil is collected; and in some places there are large pottery works. Their fishing industry is extensive, and dried fish is exported; boatbuilding is carried on to a small extent; cotton cloth is manufactured at several places, and at others the famous grass or palm-fibre cloth; whilst the dairy farms of Uhha export packages of butter. There are several London Missionary Society stations on Lake Tanganyika, also one belonging to the Roman Catholics; and a station of the African International Association is situated at Karema. Ujiji, an Arab town of some importance, stands on the eastern shore of the lake.

TANGIERS, or **TANGIER** (*Ṭanja*), a seaport of Morocco and capital of a pashalik, on the Strait of Gibraltar, about 14 miles to the east of Cape Spartel, stands on two eminences at the northwest extremity of a spacious bay. The town has a fine appearance from the sea, rising gradually in the form of an amphitheatre, and defended by walls and a castle. The streets, which are unpaved, are very narrow and crooked, and the houses, except those occupied by foreign ambassadors or consuls and a few others, are mean. The main thoroughfare is that which leads from the Bab-al-Marsa (Gate of the Port) to the Bab-al-Sok (Gate of the Market Place); the sok presents a lively spectacle, especially on Sundays and Thursdays. The manufactures of Tangiers are of little importance, consisting chiefly of coarse woollen cloth, mats, and pottery; tanning is also carried on, but the leather, though much esteemed in Europe, is inferior to that made in other parts of Morocco. The harbor is a mere roadstead, but it is the best Morocco possesses, and affords good anchorage and shelter to the largest vessels, except during the prevalence of strong winds from the northwest or east. Tangiers has a large trade with Gibraltar. The climate is temperate and healthy, but the inhabitants often suffer much in summer from deficiency of water-supply. Tangiers, which is the residence of all the foreign ministers and consuls to the court of Morocco, has a population estimated at about 20,000 of whom some 400 are Europeans.

The Roman *Tingis*, which stood in the immediate vicinity of the site of Tangiers, boasted of great antiquity; under Augustus it became a free city, and Claudius made it a Roman colony and capital of Tingitana. It was held successively by Vandals, Byzantines, and Arabs, and fell into the hands of the Portuguese towards the end of the 15th century. In 1662 it was made part of the dowry of Catherine of Braganza on her marriage with Charles II. of England; the English defended it in 1680, but, on account of its expense, dismantled it in 1684 and abandoned it to the Moors, who fortified it anew. It was bombarded by a Spanish fleet in 1790 and by the French in 1844.

TANHÄUSER, or **TANNHÄUSER**, the subject of one of the most famous of old German legends, is represented as a knight who after many wanderings comes to the Venusberg. He enters the cave where the Lady Venus holds her court, and abandons himself to a life of sensual pleasure. By and by he is overcome by remorse, and invoking the aid of the Virgin Mary, he obtains permission to return for a while to the outer world. He then goes as a pilgrim to Rome, and entreats Pope Urban to secure for him the forgiveness of his sins. The pope, who happens to have a rod in his hand, says it is as impossible for him to be pardoned as for the rod to blossom. Tanhäuser therefore departs in despair, and returns to the Lady Venus. In three days the rod begins to put forth green leaves, and the pope sends messengers in all directions in search of the penitent; but he is never seen again. This legend was at one time known in every part of Germany, and as late as 1830 it survived in a popular song at Entlibuch, a version of which was given by Uhland in his *Alte hoch- und niederdeutsche Volkslieder*. It can be traced back to the 14th century, but in its original form seems to have belonged to the period of Teutonic paganism. According to some legends, the Venusberg is the Hoselberg or Hörselberg, a hill near Eisenach associated with the Teutonic goddess of the nether world, who was known by various names, such as Hulda, Hilda, and Hel. To this goddess the name of Venus appears to have been transferred. Among the attendants of Hulda was the faithful Eckhart, and in the preface to the *Heldenbuch* he is said to sit before the Venusberg, and to warn passers-by of the dangers to which they may be exposed if they linger in the neighborhood. The legend has been reproduced by several modern German poets, and forms the subject of one of Wagner's operas.

In the 13th century, contemporary with Pope Urban IV., there was a German knight called Tanhäuser, who was well known as a minnesinger at the court of Frederick II., duke of Austria. After Duke Frederick's death Tanhäuser was received at the court of Otho II., duke of Bavaria; but, being of a restless disposition, and having wasted his fortune, he spent much time in wandering about Germany. He also went as a crusader to the Holy Land. His poems (printed in the second part of the *Minnesinger*, edited by Von der Hagen) are fresh, lively, and graceful, but lack the ideal tone which marks the writings of the earlier minnesinger. He was much esteemed by the meistersinger, and it is possible that the story of his adventurous life may have been connected with the old legend about the Venusberg.

See Kornmann, *Mons Veneris* (1614), and Grässe, *Die Sage vom Ritter Tanhäuser*, and *Der Tanhäuser und Ewige Jude*; also Zander, *Die Tanhäuser Sage und der Minnesänger Tanhäuser*.

TANJORE, a district of British India, in the Madras presidency, lying between 9° 50′ and 11° 25′ N. lat. and between 78° 55′ and 79° 55′ E. long., with an area of 3654 square miles. It forms a portion of the Southern Carnatic, and is bounded on the N. by the river Coleroon, which separates it from Trichinopoly and South Arcot districts, on the E. and S.E. by the Bay of Bengal, on the S.W. by Madura district, and on the W. by Madura and Trichinopoly and Pudukotta state. Tanjore is known as the garden of Southern India. It is well watered by an elaborate system of dams, cuts, and canals in connection with the rivers Cauvery and Coleroon, and the soil is exceedingly productive. The delta of the Cauvery occupies the flat northern part, which is highly cultivated with rice, dotted over with groves of cocoa-nut trees, and densely populated. Tanjore is a land of temples, many of them being of very early date. The great temple of Tanjore city is said to be the finest in India; it is of the 11th century, and remains in excellent preservation to the present day. The district has a coast-line of 140 miles, but communication with shipping is unsafe, owing to a heavy surf which breaks incessantly on the shore. The rainfall, as elsewhere on the Coromandel coast, varies considerably from year to year; the mean annual fall, as observed at ten stations for four years, was 47.14 inches. Tanjore is amply provided with means of communication. It is traversed by two branches of the South Indian Railway.

The census of 1881 returned the population of the district at 2,130,383 (males 1,026,528, females 1,103,855), of whom 1,939,421 were Hindus, 112,058 Mohammedans, and 78,258 Christians. Tanjore is the first district in which Protestant missions began, and now it is second only to Tinnevelly in the number of its Christian missions. These establishments were taken over in 1826 by the Society for the Propagation of the Gospel, which subsequently founded missions in several parts of the district. The total number of native

Protestants belonging to the various societies in 1881 was 8255. Roman Catholic missions in Tanjore date from the first half of the 17th century, and the number of native Roman Catholics in 1881 was 67,745. Five towns have populations exceeding 10,000, viz., Tanjore (see below), Negapatam 53,855, Combaconum 50,098, Mayavaram 23,044, and Munnargudi 19,409.

Of the total area of the district, reckoned at 2,392,117 acres, 1,468,500 were returned in 1884–85 as cultivated, and 149,228 as available for cultivation, while forests covered 21,422 acres. Rice is the staple crop, and is raised almost entirely by artificial irrigation; green crops are common; plantain and betel-vine gardens abound in the delta, where sugar-cane and tobacco are also cultivated. The chief manufactures are metal wares, silk cloths, carpets, and pith-work. Imports consist chiefly of cotton piece goods, twist and yarn, metals, timber, and betel nuts. Rice is by far the most important article of export alike by sea and land. The gross revenue in 1884–85 was £549,982 [$2,672,912.52], the land yielding £389,755 [$1,894,209.30].

The modern history of Tanjore commences with its occupation by the Mahrattas in 1678 under Venkají, the brother of Sivají the Great. The British first came into contact with Tanjore by their expedition in 1749 with a view to the restoration of a deposed rájá. In this they failed, and a subsequent expedition was bought off. The Mahrattas practically held Tanjore until 1799. In October of that year it was ceded to the East India Company in absolute sovereignty by Rájá Sharabhoji, pupil of the missionary Schwartz, the company engaging to pay the rájá of Tanjore one-fifth of the net revenue of the territory which was transferred to them, with a further sum of £35,000 [$170,100]. Rájá Sharabhoji retained only the capital and a small tract of country around. He died in 1833, and was succeeded by his son Sivají, on whose death in 1855 without an heir the house became extinct, the rights and privileges appertaining to it ceased, and Tanjore became British territory.

TANJORE, capital and administrative headquarters of the above district, is situated in 10° 47′ N. lat. and 79° 10′ 24″ E. long. As the last capital of the ancient Hindu dynasty of the Cholas, and in all ages one of the chief political, literary, and religious centres of the south, the city is full of interesting associations. Its monuments of Indian art and early civilization are of the first importance. Besides its great temple, the city is famed for its artistic manufactures, including silk carpets, jewellery *repoussé* work, copper wares, etc. It contained a population in 1881 of 54,745 (26,272 males and 28,473 females). The South Indian Railway connects Tanjore with Negapatam, its seaport on the east, and Trichinopoly on the west.

TANNAHILL, Robert (1774–1810), one of the most popular of the successors of Burns in song-writing, was a weaver in Paisley, where he was born in 1774. He was apprenticed to his father's trade at the age of twelve, in the year of the first publication of the poems of Burns, which quickened the poetic ambition of so many Scottish youths in humble life. The young apprentice studied and composed poetry as he drove the shuttle to and fro, with shelf and ink-bottle rigged up on his loom-post. Apart from his poetry, he had little variety in his life. He was shy and reserved, of small and delicate physique, and took little part in the vigorous social life of the town beyond sitting and smoking at a club of local worthies, and occasionally writing humorous verses for their amusement. He had apparently but one love affair, the heroine of which was the original of "Jessie, the Flower of Dunblane." He bade her farewell in indignant rhymes after three years' courtship. The steady routine of his trade was broken only by occasional excursions to Glasgow and the land of Burns, and a year's trial of work at Bolton. He began in 1805 to contribute verses to Glasgow and Paisley periodicals, and published an edition of his poems by subscription in 1807. Three years later the life of the quiet, gentle, diffident, and despondent poet was brought by his own act to a tragic end. Tannahill's claims to remembrance rest upon half a dozen songs, full of an exquisite feeling for nature, and so happily wedded to music that their wide popularity in Scotland is likely to be enduring. "Loudon's Bonnie Woods and Braes," "Jessie, the Flower of Dunblane," and "Gloomy Winter's Noo Awa" are the best of them.

Tannahill's centenary was celebrated with great honor at Paisley in 1874; and, in an edition by Mr. David Semple, published in 1876, there is an exhaustive and minutely learned account of all that has been preserved concerning the poet, his ancestry, and the occasions of his various poems.

TANNIN, a generic name for a class of vegetable substances which, as the name indicates, are all available for tanning, meaning the conversion of animal hide into leather. Tannin is widely diffused throughout the vegetable kingdom. An enumeration of the principal materials which form the commercial sources of the substance will be found under Leather, vol. xiv. p. 381, and in various special articles referred to from that heading.

Our chemical knowledge on the subject is very limited; and as long as we know no better, each of the various tanning materials must be viewed as containing a "tannin" of its own kind.[1] Only a few have as yet been obtained in a state approximating chemical purity. The following characters are common to them all:

(1) All are colorless or little-colored non-volatile solids, soluble in water and in alcohol; the solution has an astringent taste.

(2) They color blue litmus paper feebly red, yet all unite with the alkalies into soluble salts; the solutions of these eagerly absorb oxygen from the air, with formation of dark-colored products.

(3) They form insoluble salts with the oxides of lead, zinc, copper, producible by addition of solution of the tannin to one of the respective acetate.

(4) They form very dark-colored (green or blue) compounds with ferric oxide, conveniently producible by addition of the tannin to ferric or ferroso-ferric acetate. Ordinary old-fashioned black (gall-nut) ink may be quoted as an illustration.

(5) Tannin solutions precipitate gelatine as an insoluble compound, generally assumed to be chemically similar to the substance of leather.

(6) If a piece of raw hide be placed in a solution of any tannin it imbibes the later with formation of Leather (*q.v.*).

(7) Aqueous tannin-solutions, if mixed with dilute sulphuric acid, are readily oxidized by solution of permanganate of potash, which, being reduced to manganous salt, loses its intense violet color.

Upon the last two propositions Löwenthal has based a convenient method for the assaying of tannin materials. A known weight of the substance to be analyzed (say sumach) is extracted with water, and the extract diluted to a known volume. An aliquot part of the extract is then mixed with a certain proportion of a standard solution of indigo-carmin and of sulphuric acid, and after a large dilution with water, standard permanganate is dropped in from a burette (graduated glass tube) until the color of the indigo is completely discharged. After deducting the volume of reagent which would have been taken up by the indigo alone, the rest is put down as corresponding to the "permanganate reducers generally." Another measured volume of the extract is then poured over a sufficient weight of dry shavings of raw hide, after having been suitably diluted, and the whole is allowed to stand until the tannin has all passed into the hide. The liquid is then filtered, and a measured volume, corresponding to exactly the quantity of extract used for the assay, tested with permanganate. The volume of reagent used this time is deducted from that used in the assay as a correction. From the net permanganate the weight of pure gallotannic acid which it would oxidize is calculated on the basis of standard experiments, and from this weight the "percentage of tannin" is deduced. The method is purely empirical, and the results are of no value unless obtained according to a rigorously prescribed mode of procedure. Of individual tannins that of the gall-nuts, known as *gallotanic acid*, is best known. For its preparation (according to Pélouze) powdered gall-nuts are placed in an apparatus for extraction "by displacement," and in it soaked in a mixture of 9 parts of ether and 1 part of water for twenty-four hours. The liquid is then allowed to drain off, and the residue washed with aqueous ether. The liquid on standing separates into two layers,—

---

[1] Coffee beans and tea leaves contain peculiar tannins.

a lower heavy layer, which contains the tannin, and an upper more purely ethereal layer, which contains gallic acid and other impurities. The lower layer is drawn off, washed once or twice with ether, and then evaporated to dryness at a gentle heat; the tannin remains as a porous friable mass of a slightly grayish-yellow color. This is the tannin of the pharmaceutist.

Such tannin is not by any means an absolutely unitary substance. Its solution, if allowed to stand in the presence of a ferment which is naturally present in gall-nut extract, or more readily if boiled with sulphuric acid, yields a large proportion of *gallic acid*, which is easily obtained in pure crystals. According to Strecker, glucose is formed at the same time, whence he viewed tannin as a glucoside (see SUGAR). But this is now recognized as a mistake, since Hugo Schiff showed that *pure* tannin is only digallic acid, $C_{14}H_{10}O_9 = 2C_7H_6O_5$ (gallic acid) minus $1H_2O$. Pure tannin, according to Schiff, can be obtained by dehydrating pure gallic acid by means of chloride of acetyl. The tannin of the Chinese gall-nuts seems to be identical with gallotannic acid.

Quercitannic Acid.—The tannin of oak bark is certainly different from gallotannic acid, because it yields no gallic acid when boiled with dilute vitriol. Etti (*Jahresb. über die Fortschr. der Chemie* for 1880, p. 898) prepares it by extracting the powdered bark with dilute alcohol at a gentle heat, adding ordinary ether to the alcoholic extract, and shaking out the tannin with acetic ether. The acetic ether extract is distilled to recover the solvent, the residue filtered, and the filtrate evaporated to dryness to obtain the pure (?) tannin as a reddish-white powder of the composition $C_{17}H_{16}O_9$. At 130–140° C. it loses water and forms *phlobaphen*, $C_{34}H_{30}O_{17}$, a brown solid insoluble in water but soluble in solution of the tannin. Quercitanic acid forms quite a series of such anhydrides; $C_{34}H_{30}O_{17}$; $C_{34}H_{28}O_{16}$; $C_{34}H_{26}O_{15}$; $C_{34}H_{24}O_{14}$. Some, if not all, of these are contained in aqueous oak-bark extract, and they play an important part in its application for tanning. According to Etti, quercitannic acid is a tri-methyl substitution-product of digallic acid, $C_{14}H_{10}O_9$ minus $3H$ plus $3CH_3 = C_{17}H_{16}O_9$.

Besides these two tannins, those of coffee and cachou are the only ones which have been obtained in a relatively definite form.

TANNING. See LEATHER.

TANTALUM. A rare element closely allied to NIOBIUM. See vol. xvii. p. 527.

TANTALUS, a hero of ancient Greek myth and legend. He was a son of Zeus and Pluto ("Wealth"), and became the father of Pelops, Proteus, and Niobe. He dwelt in splendor on Mount Sipylus near Smyrna, and was admitted to the table of the gods themselves. But he abused the divine favor by revealing to mankind the secrets he had learned in heaven, or by killing his son Pelops and serving him up to the gods at table. Another story was that he stole nectar and ambrosia from heaven and gave them to men. According to others, Pandareus stole a golden dog which guarded the temple of Zeus in Crete and gave it to Tantalus to take care of. But, when Pandareus demanded the dog back, Tantalus denied that he had received it. Therefore Zeus turned Pandareus into a stone, and flung down Tantalus with Mount Sipylus on the top of him. The punishment of Tantalus in the lower world was famous. He stood up to his neck in water, which fled from him when he tried to drink of it; and over his head hung fruits which the wind wafted away whenever he tried to grasp them. From this myth is derived the English word "tantalize." Another story is that a rock hung over his head ready to fall and crush him. The tomb of Tantalus on Mount Sipylus was pointed out in antiquity, and has been in modern times identified by Texier with the great cairn beneath Old Magnesia; but Prof. W. M. Ramsay inclines to identify it with a remarkable rock-cut tomb beside Magnesia. The story of Tantalus contains a reminiscence of a semi-Greek kingdom which had its seat at Sipylus, the oldest and holiest city of Lydia, and one of the chief birthplaces of early Greek civilization. Of this ancient city the remains are still visible on the northern slope of Mount Sipylus, and about 4 miles east of Magnesia. They consist of sepulchral mounds, rock-cut tombs, and a small acropolis perched on an almost inaccessible crag which juts out from the nearly perpendicular limestone wall of Mount Sipylus. There was a tradition in antiquity that the city of Tantalus had been swallowed up in a lake on the mountain; but the legend may, as Prof. W. M. Ramsay thinks, have been suggested by the vast ravine which yawns beneath the acropolis.[1] This acropolis is too small ever to have been the seat of a great empire; rather, like Pessinus and other great religious centres of Asia Minor, it may have been "the seat of a priestly suzerainty maintained over the *hiero-douloi* [sacred slaves] of the surrounding district." Connected as the city was on the one hand with the sea, and on the other with the capital of the ancient kingdom of Phrygia by means of the "royal road," it was a natural meeting-place for Greek and Oriental culture. A comparison of the art of Phrygia with the early art of Mycenæ and Olympia has fully confirmed the legend which connects the family of Tantalus with the Peloponnesus.

See PELOPS, PHRYGIA, and a paper by Prof. W. M. Ramsay in *Journal of Hellenic Studies*, iii. p. 33 *sq.*

TAOISM. See LÂO-TSZE.

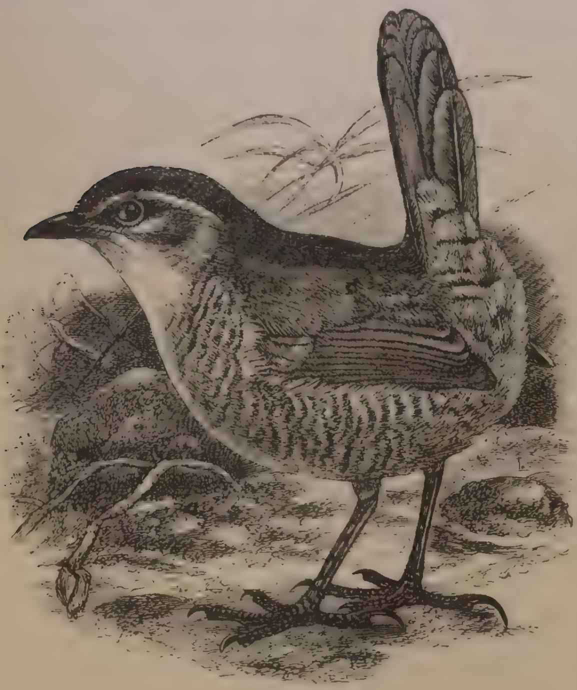
TAORMINA (*Tauromenium*), now an important village of about 3000 inhabitants, is magnificently situated at the edge of a precipitous cliff 900 feet high on the east coast of Sicily, about 32 miles from Messina and the same from Catania. The original city was founded by a tribe of Siculi after the destruction of the neighboring city of Naxos in 403 B.C. by Dionysius of Syracuse. It was built on the hill of Taurus, whence came the name Ταυρομένιον (Diod. xiv. 58). In 358 B.C. the city was increased by the settlement of the exiled survivors from Naxos, which was only 3 miles distant; and hence Pliny (*H. N.*, iii. 8) speaks of Naxos as having been the original name of Tauromenium. Owing to its commanding site, the city has frequently been the scene of important struggles. When with the rest of Sicily it passed into the possession of the Romans, it shared with two other Sicilian cities the privileges of a "civitas fœderata." During the Servile War (134–132 B.C.) Tauromenium was occupied by a body of rebel slaves, but was finally taken by the consul Rupilios, and the whole garrison slaughtered. In 36 B.C. it was one of Sextus Pompey's chief strongholds in his war with Augustus, who after his victory established a Roman colony there. Under the empire it was a flourishing city, famed for its wine (Pliny, *H. N.*, xiv. 6) and red mullets (Juv., v. 93). In 902 A.D. it was taken from the Byzantine emperor by the Saracens, who called the place Moezzia. In 1078 it was captured by the Normans. A large number of ancient remains bear witness to its former importance. Fine autonomous silver coins of *c.* 300 B.C. exist with *obv.*, a laureated head of Apollo, and *rev.* a tripod, with the legend ΤΑΥΡΟΜΕΝΙΤΑΝ, and a magistrate's initials AI. The theatre is, next to that at Aspendus (Pamphylia), the best preserved in existence. It is Greek in plan, but the existing structure belongs mostly to the Roman period, and is especially remarkable for the preservation of its lofty scena wall, and two large chambers which form entrance-porches to the cavea. It is excavated in an elevated peak of rock, and commands one of the most magnificent views in the world, with Mount Etna in the distance. Remains of five piscinæ and a large bath, popularly called a naumachia, still exist, together with remains of the ancient city wall and that of the arx.

See Serradifalco, *Antichità di Sicilia*, Palermo, 1834–42, vol. v.; Hittorff and Zanth, *Architecture Antique de la Sicile*, Paris, 1870.

---

[1] Legends of submerged cities and castles are common in different parts of Europe. It has been suggested that they are confused recollections of the ancient villages built on piles in lakes (Wood-Martin, *Lake Dwellings of Ireland*, p. 28).

TAPACULO, the name[1] given in Chili to a bird of singular appearance,—the *Pteroptochus albicollis* of ornithology,—and, throughout this series of articles (Birds, vol. iii. p. 644; Ornithology, vol. xviii. p. 44, *et alibi*), applied in an extended sense to its allied forms, which are now found to constitute a small Family, *Pteroptochidæ*, belonging to the Tracheophonous division of *Passeres*, and therefore peculiar to South America. About 20 species, which are disposed by Mr. Sclater (*Ibis*, 1874, pp. 189–206) in 8 genera, are believed to belong to this group.



Tapaculo.

The species of the Family first made known is *Scytalopus magellanicus*, originally described in 1783 by Latham (*Synopsis*, iv. p. 464) as a Warbler. Even in 1836 Gould not unnaturally took it for a Wren, when establishing the genus to which it is now referred; but some ten years after Johannes Müller found that *Scytalopus*, together with the true Tapaculo, which was first described by Kittlitz in 1830, possessed anatomical characters that removed them far from any position previously assigned to them, and determined their true place as above given. In the meanwhile a kindred form, *Hylactes*, also first described in 1830, had been shown by Eyton to have some very exceptional osteological features, and these were found to be also common to *Pteroptochus* and *Scytalopus*. In 1860 Prof. Cabanis recognized the *Pteroptochidæ* as a distinct Family, but made it also include *Menura* (*cf.* Lyre-bird, vol. xv. p. 116), and in 1874 Mr. Sclater (*ut supra*) thought that *Atrichia* (*cf.* Scrub-bird, vol. xxi. p. 580) might belong here. It was Garrod in 1876 and 1877 who finally divested the Family of these aliens, but, until examples of some of the other genera have been anatomically examined, it may not be safe to say that they all belong to the *Pteroptochidæ*.

The true Tapaculo (*P. albicollis*) has a general resemblance in plumage to the females of some of the smaller Shrikes (*Lanius*), and to a cursory observer its skin might pass for that of one; but its shortened wings and powerful feet would on closer inspection at once reveal the difference. In life, however, its appearance must be wholly unlike, for it rarely flies, hops actively on the ground or among bushes, with its tail erect or turned towards its head, and continually utters various and strange notes,—some, says Mr. Darwin, are "like the cooing of doves, others like the bubbling of water, and many defy all similes." The "Turco," *Hylactes megapodius*, is larger, with greatly developed feet and claws, but is very similar in color and habits. Two more species of *Hylactes* are known, and one other of *Pteroptochus*, all of which are peculiar to Chili or Patagonia. The species of *Scytalopus* are as small as Wrens, mostly of a dark color, and inhabit parts of Brazil and Colombia, one of them occurring so far northward as Bogota. (A. N.)

TAPESTRY. See Textiles.

TAPE-WORMS, or Cestoda, are a group of worms forming one of the three main divisions of the *Platyhelminthes*, the other two being the *Turbellaria* (see Planarians and Nemertines) and *Trematoda* (see Trematoda). They have been defined as follows: "Flat worms without mouth or alimentary canal, which typically develop by alternation of generations, by budding from a generally pear-shaped nurse, with which they remain united for a lengthened period as a ribbon-like colony or 'strobila.' The individual joints of the colony, *i.e*, the sexual animals or 'proglottides,' increase in size and maturity as they are removed farther from their origin by the intercalation of new buds, but are not distinguished in any special way. The nurse, however, known by the name of the 'head' (*scolex*) is provided with four or two suckers, and usually with curved claw-like hooks. The dorsal and ventral surfaces of the head are perfectly identical, so that the arrangement of the hooks presents a strikingly radiate appearance. By means of this apparatus the worms fasten themselves on the intestinal membrane of their hosts, which (except in the case of the otherwise peculiar *Archigetes*) all belong to the *Vertebrata*. The nurses develop from little round six-hooked embryos in a more or less complicated fashion as so-called 'bladder-worms.' The latter inhabit very diverse, but usually parenchymatous, organs of the higher and lower animals, and are thence passively transferred to the intestine of their subsequent host" (Leuckart, **1**,[2] p. 270).

Historical Sketch.—Certain forms of Cestodes have been known from time immemorial. The hydatid cyst is alluded to by early medical writers, and Aristotle speaks of examining the tongue of pigs to ascertain the presence of bladder-worms. By this author and Hippocrates the Cestodes and other flat worms are spoken of as ἕλμινθες πλατεῖαι, in opposition to the στρογγύλαι or "round worms"; the word *Tænia* (Gr. ταινία) does not occur in Greek authors, but is first used by the Romans (Pliny, *H. N.*, xi. 33). In the treatises of the Middle Ages the tape-worm figured as *Lumbricus latus*, only one species being recognized. Felix Plater (**23**) separated *Bothriocephalus* from the other human tape-worms, and Andry (**24**) gave it the name *Ténia à épine*, mistaking the nodular generative organs for vertebræ. The appellation *Bothriocephalus latus* dates from Bremser, 1819 (**25**). Like other *Entozoa*, the tape-worms and bladder-worms were supposed to arise by spontaneous generation; it was found, however, that animal forms strikingly like the *Entozoa* sometimes lived freely. Pallas (**19**), seeing that the eggs of intestinal worms are expelled from the animals in which they live, and may remain for some time unaltered in water, suggested the hypothesis that the *Entozoa* agree with other animals in originating from eggs which can be carried from one animal to another. He also supposed that they reach the liver and other internal organs by means of the blood-stream. Other authorities endeavored to explain the presence of *Entozoa* by supposing that they were transmitted from parents to children. Von Siebold (**26**) in 1838 discovered the six-hooked embryos of *Tænia*, and came to the conclusion that they could only pass into the fully-formed animal by a kind of metamorphosis. The subject was fully discussed by Eschricht (**27**), who endeavored to prove that this phenomenon was of common occurrence among the *Entozoa*. Shortly afterwards appeared Steenstrup's famous work upon the alternation of generations (**28**), which furnished a ready explanation of the isolated facts till then observed regarding the Cestodes. The most important advances in modern times have been due to the introduction of helminthological experiment by Küchenmeister, by means of which the demonstration has been furnished that certain bladder-worms are the larval stages of particular tape-worms. The first of these experiments took place in 1851, when Küchenmeister fed a dog with bladder-worms from the rabbit, and a cat with specimens from the mouse, and succeeded in rearing tape-worms in their intestines (**29**). Similar investigations on different species have been made by Van Beneden, Leuckart, and others. Of systematic treatises the most important are those of Rudolphi (**35**), Diesing (**20**), and Van Beneden (**13**), while Von Linstow, in addition to numerous scattered papers (**30, 36**), has given us an invaluable list of hosts with their respective parasites (**21**).

---

[1] Of Spanish origin, it is intended as a reproof to the bird for the shameless way in which, by erecting its tail, it exposes its hinder parts. It has been sometimes misspelt "Tapacolo," as by Mr. Darwin, who gave (*Journal of Researches*, chap. xii.) a brief but entertaining account of the habits of this bird and its relative, *Hylactes megapodius*, called by the Chilenos "El Turco."

[2] These figures refer to the bibliography, p. 61.

Anatomy.

In considering the anatomical peculiarities of the *Cestoda* it will be convenient to describe one particular species and afterwards to indicate the chief differences presented by other members of the group. For this purpose *Tænia saginata*, Göze (*T. mediocanellata*, Küchenmeister), may be selected as a type, as it has been perhaps more studied than any other, and is one of the species most commonly found in man; for further details, see Sommer (**31**).

Dimensions.—An average specimen of this tape-worm (Fig. 1, A) will measure in a state of moderate contraction about 500 cm., and consist of nearly 1400 segments; of those which immediately follow the head more than 250 will be found within a length of 5 cm.; they gradually widen posteriorly, until the widest, which are situated about halfway down the chain, have a breadth of 14 mm. and a length of 6 mm.; whilst the terminal segments measure 5 mm. in breadth by 19 mm. in length.

The head (Fig. 1, B) is spheroidal, 1.5 mm. in diameter, and bears on its lateral surface four equidistant suckers, which serve for the attachment of the whole worm. After death these are generally retracted, but during life they can be protruded and moved in all directions. They are a special development of the musculature of the body-wall, the radial fibres being the most conspicuous. The tape-worm now being described is abnormal, inasmuch as the front of its head is not provided with a circlet of hooks; these are well seen, however, in the other common human tape-worm (*Tænia solium*), which bears a double ring of them, situated around a button-shaped muscular pad (*rostellum*) which forms the apex of the head (Fig. 1, C). By the varying contraction of the separate parts of this organ the hooks may be moved in different directions, and when the worm is attaching itself they are first extended directly forwards, and then brought back so as to force the rostellum into the tissues of the host. Each hook has a broad bifid base, to which the muscles are attached, supporting a long curved point. In *Tænia saginata*, to the consideration of which we now return, the rostellum is quite rudimentary, and has been described by earlier authors as a fifth sucker or even as a mouth; it is interesting to note that during its incipient stages it bears a number of minute spines homologous with the hooks of other species. The head contains furthermore the anterior portions of the nervous and excretory systems. The latter of these consists of an annular vessel placed immediately below the rostellum, from which four canals, corresponding to the four suckers, pass backwards; two of these gradually disappear, leaving two which pursue their course down the proglottides, in connection with which they will be again alluded to, and open at the hinder extremity of the worm by a common pore. The nervous system of the Cestodes was long sought in vain: although some early investigators described a ganglion, they were unable to give any satisfactory proof of its existence, this having been first furnished by Schneider. It seems generally to consist of a central ganglion lying within the head, from which two cords proceed backwards; these were regarded by Sommer and Landois as part of the alimentary system. Niemiec (**6**) has recently given a detailed account of its structure in several different species, and its relations have been discussed by Lang (**7**).

The proglottides arise by a species of budding in the narrow neck which immediately succeeds the head; they are separated from each other by grooves, which are at first so shallow and indistinct that it is impossible to say with certainty where the segmentation really begins. The proglottides which have attained sexual maturity are situated some 30–40 cm. from the head, and measure 1.5 mm. in length by 5 mm. in breadth. The segments, like the head, consist of a solid mass of tissue in which the various organs are imbedded. Like the Trematodes, the Cestodes were long thought to have no body-cavity or cœlom, and hence were called "parenchymatous" worms. Recently, however, a series of intercellular spaces have been described by Fraipont (**8**) as leading into the terminal excretory organs, and these spaces have been interpreted both by himself and others as the homologue of a body-cavity, although this opinion has not been allowed to pass unchallenged (see Pintner, **9**). The surface of the body is covered by a thin clear homogeneous cuticle, which, according to some authorities, is perforated by fine closely-set pores. The hooks which

G, six-hooked embryo, highly magnified.

have been described above, as well as the small spines and bristles found in certain species, are developments of this cuticle. This external covering cannot, according to Leuckart (1, p. 289), be regarded as homologous with the cuticle of other invertebrates, inasmuch as it is not a secretion from a special layer of subjacent cells, but is "the structureless limiting membrane of the connective tissue substance, and is comparable with the so-called basement-membrane found in the other flat-worms . . . between the muscular layer and the dermal epithelium." It is to be observed, however, that this view has by no means found universal acceptance (see Steudener, **10**), and it is *a priori* improbable, since the Cestodes (and Trematodes) would thus form an exception to the general rule by which all animals are clad with an epithelium derived from the embryonic ectoderm. The subcuticular layer is described as consisting of long fusiform cells (probably modified connective-tissue cells) disposed perpendicularly to the cuticle. It seems possible that they are in direct connection with the transverse muscles of the body. The matrix of the Cestode body consists of connective tissue, the cells composing which are seldom provided with a distinct membrane, and sometimes can only be separately distinguished by their nuclei. The layer of muscles (see below) separates this matrix into a central and a cortical portion. Distributed in it, and especially in its cortical portion, are numerous calcareous corpuscles, which are generally spheroidal in form, varying up to 0.019 mm. in diameter and concentrically laminated; they contain a large amount (often 20 per cent.) of lime salts, diffused through an organic basis, from which the salts can be removed with effervescence by the action of acids. These corpuscles have been variously interpreted by the older authors as eggs, or as lymph or blood corpuscles, but the only theories which have been seriously maintained in modern times are: (1) that they are skeletal (Von Siebold); (2) that they are excretory (Claparède, Griesbach); or (3) that they form a reserve store of calcareous material to be used either in counteracting the acid digestive juices of the host or for the production of egg-shells (Leuckart, **1**, p. 283).

The muscular system consists of three sets of fibres—longitudinal, transverse, and sagittal. The first are the best developed, and run down the inner part of the cortical layer in the form of strong bands; the second set lie immediately below them and pass across the body in the form of two flat muscular plates, which converge towards each other as they approach the margins of the proglottis; the sagittal muscles run primitively straight from one flat surface of the body to the other, but their direction is much modified after the growth of the genital organs, between the various parts of which they lie as isolated bundles; they are the weakest of all the sets. The muscular fibres are non-striated, and when they are fully developed no nucleus can be detected in them. They taper towards the extremities, sometimes branching dichotomously, and, as above mentioned, a connection has been asserted to be visible between them and the subcuticular cells.

The excretory system in the proglottides consists of two or four longitudinal canals which lie along their two narrow margins (Fig. 1, D, *ex.*). The origin of these in the head has been already noted, and they pass continuously down the whole worm until they open into a vesicle at the posterior extremity of the terminal segment. In the hinder part of each proglottis they are connected by a transverse vessel (Fig. 1, D, *tr.*), immediately above which a valve is formed by a duplicature of the wall, so that it is impossible to inject the excretory system from behind whilst fluid can be readily forced along it from before backwards. Fraipont has drawn a distinction between ascending and descending canals. Excretory openings have been described by various observers in the anterior portion of the worm, near the suckers (Wagener, **11**; Fraipont, **8**; Riehm, **12**), and, although their presence is denied by Pintner (**9**), there seems sufficient evidence to show that they are more generally present than was formerly supposed. A ramifying network of smaller vessels connected with the main trunks just described is found in the more superficial parenchyma, and this in its turn gives off still finer capillaries which terminate in ciliated funnels. According to Fraipont these open into the intercellular lacunæ which are the representatives of the cœlom (see above), whilst Pintner maintains that the terminal funnels are completely closed, and are to be regarded as unicellular glands. The subject, however, is one of extreme difficulty and demands further investigation. It is worthy of notice that each of the three systems of canals above described maintains its proper diameter throughout, and that no intermediate sizes can be found. The "plasmatic vascular system" described by Sommer and Landois, and regarded by them as part of the alimentary system, consists partly of some of these delicate canals and partly of the two cords of the nervous system. The main canals open posteriorly into a pulsatile vesicle, at the end of the last proglottis; when, however, some of these have been cast off the opening may be either by a shortened tranverse vesicle, as Leuckart (**1**) maintains to be the case in the present species, or by separate openings, one for each canal.

The reproductive organs are serially repeated in the proglottides, each of which contains a complete set of male and female organs (Fig. 1, D). The male organs may be discussed first. The testes (*t.*, *t.*) are very numerous and scattered throughout the greater part of the proglottis; they are round vesicles (0.15 mm. in diameter) containing spermatozoa, and attached like berries to the terminal ramifications of the vas deferens (*v.d.*); these gradually unite, forming larger and larger branches until they reach the main canal, which runs in a series of coils transversely half-way across the joint a little behind its middle, and ends in a common cloaca (*cl.*), which receives both the male and female organs, and is connected with the outer world by the porus genitalis. The outer portion of the vas has a thickened muscular wall, and this part of it is capable of extrusion and retraction, thus forming the male intromittent organ or "cirrus" (*c.p.*). The cuticle which lines all the distal portion of the vas deferens is here thin and delicate and armed with a series of minute spines, which are directed backwards (*Echeneibothrium*). The cirrus in the present species is very short, but in other forms its length is sometimes considerable. The protrusion is effected by circular muscles placed around the end of the vas deferens, while the retraction is brought about by special longitudinal fibres, lying along the walls of the evaginable portion.

The female organs may be most conveniently studied by tracing them inwards from the cloaca. The vagina (*v.*) opens immediately posterior to the vas deferens, and like it is lined by a continuation of the external cuticle. After passing about half-way across the segment it bends backwards and terminates in a small cyst, the receptaculum seminis (Fig. 1, E, *r.s.*); this receives and stores up the male fertilizing elements, retaining them until the ova are ripe. From its posterior extremity there passes a thin-walled canal, wider than the vagina (*f.*), which serves to convey the spermatozoa to the ova, and hence is termed the "fertilizing canal" (Befruchtungs-canal of German authors). It unites with the common oviduct, a tube formed by the union of the two oviducts (*o.d.*), and the two together pass backwards into a spherical glandular structure, called from its discoverer "Mehlis's body" or the shell-gland (Fig. 1, D and E, *sh.g.*). Within this apparatus it receives the duct of the yolk-gland (*y.g.*), and then passes directly forwards to open into the uterus. The ovaries (*ov.*) are two in number, situated one on each side of the middle line of the body; they are fan-shaped, and consist of a system of blind tubules situated on a branched efferent duct. The cells of the ovary (primitive eggs) have a sharp contour and a large nucleus; the yolk-gland (*y.g.*) is very similar to the ovaries, behind and between which it is situated, but is distinguished by various histological details (it is called "ovary" by Moniez). The shell-gland, formerly regarded as the ovary, consists of closely compressed nucleated cells, and is provided with small thin ducts opening into the narrow internal cavity of the organ. The uterus (*ut.*), in its early stage of development, is a long straight tube, lying almost in the longitudinal axis of the proglottis, and receiving posteriorly the oviduct after it emerges from the shell-gland (Fig. 1, E, *ut.*). From what has been said it will appear that the ova on their way down the common oviduct are impregnated as they pass the end of the fertilizing canal, and then receive in succession, first their supply of food-yolk and their shell, during their sojourn in Mehlis's body, after which they go forwards into the uterus, where they undergo the first stages of their development. The uterus assumes a very different shape as it becomes distended with eggs, which are far too numerous to be contained in a simple straight tube; small protuberances arise from its walls, growing rapidly and bifurcating here and there, so as to produce the complicated branched appearance seen in Fig. 1, F. As the uterus grows, the male, and later the female, genitalia degenerate and disappear, and in the proglottides which are ready to be liberated the only organ visible is the distended uterus. One of the most characteristic peculiarities in the sexual system just described is that there is no passage by which the ripe eggs can make their exit from the proglottis; these are therefore extruded only on its rupture; a very different state of things obtains in the genus *Bothriocephalus* (see below). Self-impregnation certainly occurs, and is probably the rule; it is obvious that the contrary case can only happen where two individuals lie side by side within the same host. Furthermore, the cirrus has been seen protruded into the vagina of the same joint, and the emission of sperm has been witnessed (Leuckart, 1; Van Beneden, 13, p. 601).

The eggs are ovoid or spherical, and consist of the germ-cell (nucleus and protoplasm) with an albuminous enveloping substance, which is again surrounded by a thin transparent skin. The shell frequently presents one or more appendages, probably the secretion of the shell-gland drawn out into threads. The structure of the egg has been best studied in *Tænia serrata* (Van Beneden, 14), where it consists of a delicate shell containing a germ-cell with a quantity of secondary yolk; the former divides into a "granular" cell, which segments no further, and an "embryonic" globe, which again divides into a number of cells, of which three are larger and constitute the "albuminogenous layer," whilst the remainder are smaller and form the "embryonic mass," and secrete a delicate superficial cuticle, the cell-limits being indistinct. In the embryonic mass from three to five flattened cells form a chitinogenous layer, and give origin to a superficial homogeneous coat, a shell of radially disposed chitinoid cylinders, and an internal faintly striated lining, whilst the remaining cells become the six-hooked embryo or proscolex, a superficial layer to which the hooks belong, and a central mass of clearer cells. When the proscolex is mature the original egg-shell and the albuminogenous layer disappear, and only the chitinoid coats remain.

The proglottides are cast off by muscular action; the fibres are not continuous between the successive segments, so that these are connected merely by soft connective tissue, which readily gives way; the rupture takes place through the tranverse vessel above described, and, as the hinder margin of the proglottis contracts forcibly when the next one has left it, the transverse vessel gives rise to the rounded vesicle which forms the termination of the excretory system.

Life-History and Development.

The six-hooked embryo (Fig. 1, G) may be conveyed to the intermediate host in several ways, but the commonest is for it to be taken into the alimentary canal along with food to which it may have adhered, or with water in which it was swimming; the infection may take place either by means of free eggs or by whole proglottides. In the latter case the soft tissues are first digested by the gastric juice of the host, and in either case the egg-shell is dissolved or rendered so brittle that the embryo readily escapes by the movement of its hooks. The proscolex, after spending a longer or shorter time free in the stomach or intestine, proceeds to perforate the wall of these organs by means of active burrowing motions. Although the embryo of a *Tænia* has only once been captured in its progress through the wall of the alimentary canal (Raum, 15, p. 28), there can be no doubt that this is the route by which it usually proceeds, and that its next locality is a bloodvessel, probably some small branch of the portal vein, in the blood of which it has been found by more than one observer. This would explain the frequency with which the next stage is found in the liver. There seems, however, reason to believe that many embryos penetrate the intestinal wall completely and reach the body-cavity, in which they can wander freely. When the six-hooked embryo has reached its resting-place, which in addition to the liver may be lung, muscles, brain, connective tissue, or eye, it at once commences its further development, and in a few days becomes visible to the naked eye. Like any other foreign body, it causes a proliferation of cells, which in due time form a sheath of connective tissue, with a cellular lining, and smooth like a serous cavity within; this covering, however, is not found when the parasite is situated in the brain or the eye. The embryo now grows in size, generally becoming somewhat elongated, and the hooks drop off. Sometimes they can be found lying detached in the connective-tissue sheath. The central cells enlarge and become clear, and in all the *Tæniæ* they liquefy, forming a quantity of fluid which fills the centre of the bladder-worm. At this stage the larvæ constitute the so-called "measles" of beef (that of pork being due to *Cysticercus cellulosæ*, the immature stage of *Tænia solium*); they are ovoid vesicles lying between the muscle fibres and varying in length from 4 to 8 mm. and being usually about 3 mm. in diameter (Fig. 2, A). At a point on one side of the bladder there appears a small thickening, the meniscus or rudiment of the future head; this is soon followed by an invagination of the cuticle (Fig. 2, B). When the rudimentary head thus formed is about 0.2 mm. in length (the bladder being 1.5 mm. in diameter) the formation of muscles in its walls commences. At four equidistant points near the bottom of the invagination the suckers are developed, and at the lowest part of the cavity the rostellum (and the double circlet of hooks in the armed species) is formed. Surrounding the head-rudiment on that surface which is towards the cavity of the bladder is a thin layer, known as the "receptacle." This is best seen in *Cysticercus cellulosæ*, in which there is also a very characteristic bend or kink in the pedicle of invagination, which in most other bladder-worms remains straight (see Fig. 2, C). The rudiments of the vascular system of the bladder have already appeared before the formation of the head, and now they extend into it as four longitudinal vessels, which become connected at the bottom of the invagination by a circular vessel. About this time, too, the calcareous corpuscles above described make their appearance. When the hooks and suckers are fully formed, the head undergoes a process of evagination, so that what was previously a hollow cavity becomes a solid cylinder, and the hooks, which were below the suckers, come to lie above them. Mature bladder-worms vary in size from *Cysticercus fasciolaris*, the size of a pea, to *Cysticercus tenuicollis*, six inches or more in length.

The development into the adult tape-worm takes place only after the *Cysticercus* has been swallowed by the permanent or definitive host. The course of this metamorphosis has been followed experimentally, and it has been found that first the bladder and next the neck of the worm are dissolved by the gastric juice. The head only is left; in the moist warmth of the intestine its suckers and rostellum exhibit very lively motions, which serve to bring about its attachment to the intestinal wall. It gradually increases in length, and the formation of segments speedily commences.

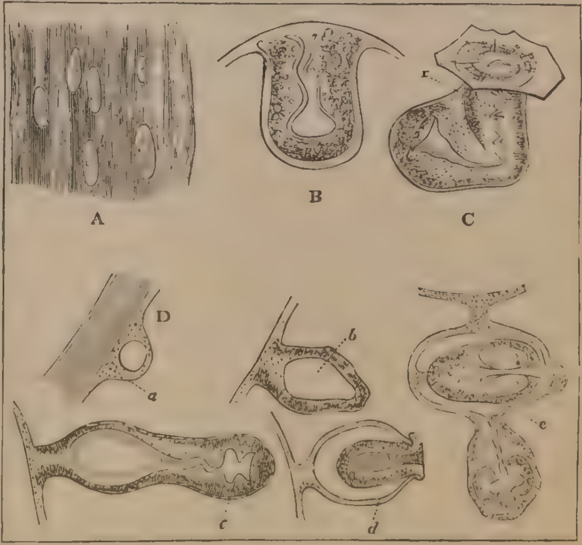

FIG. 2.—Development of *Tænia* (from Leuckart.) A, *Cysticercus bovis* in beef; nat. size. B, invaginated head of a *Cysticercus* before the formation of the suckers; × 25. C, invaginated head of *Cysticercus cellulosæ*, showing the bent neck and receptacle *r*; × 30. D, stages in the development of the brood-capsules in *Echinococcus*; *a*, the thickening of the parenchyma of the bladder; *b*, subsequent formation of a cavity in it; *c*, development of the suckers; *d*, a capsule with one head inverted into its cavity; *e*, a capsule with two heads; × 90.

The life-history of the Cestodes is generally summed up as consisting of three different forms: (1) the proscolex, or six-hooked embryo, which gives rise to the bladder-worm; (2) the scolex, which developes the chain or strobila by a process of budding; and (3) the proglottis, or sexual animal, which produces eggs. Each of these three forms has certain claims to be regarded as a zoological "individual." Van Beneden (13, *Vers Int.*, p. 251) has laid great stress upon the correspondence between a Trematode and a ripe proglottis, and it has been since pointed out that a proglottis may under favorable circumstances (that is, within the intestine) continue to grow after being detached from the parent chain; it cannot be said, however, that the evidence upon which this rests is quite incontrovertible. Regarded from this point of view the life-history of the tape-worms furnishes an admirable instance of the alternation of generations. The individuality of the proglottides, however, although maintained by authorities so eminent as

Leuckart, is by no means universally accepted; a distinction has been drawn between their formation and true budding seen in other animal colonies, such as the *Polyzoa;* and Riehm, in a recent work (12), has pointed out that the casting-off of these sexual segments is in some respects comparable to the detachment of the hectocotylized arm of a Cephalopod, and the formation of new joints to the development of an Oligochætous worm from a few segments; furthermore, certain organs—for example, the nervous and excretory systems—are continuous throughout the whole chain, and an isolated proglottis is unable to maintain its existence for more than a very limited period. According to this view, alternation of generations only occurs in Cestodes in forms such as *Cœnurus*, where there is a proliferation of heads in the wall of the bladder.[1]

The Cestode larvæ corresponding to the stage which has just been described present considerable variations both in form and structure, and upon these classifications of the group have been based, and generic names have been given to the different forms; Von Linstow (36) has, however, pointed out the undesirableness of this, as they are all parts of the life-history of one genus, *Tænia*. The most recent arrangement is that of Villot (16), which is as follows:

I. The caudal bladder arises from the proscolex by simple growth and structural modification, without the formation of any new parts. A larger or smaller quantity of fluid is present, and also a connective-tissue sheath; the host is a vertebrate. *Cysticercus* (true bladder-worms), *Piestocystis, Cœnurus, Echinococcus.*

II. The caudal bladder arises from the proscolex by budding, that is, by the formation of new parts; there is no connective-tissue sheath, and the host is an invertebrate. *Cysticercoidei*, Leuckart. (*a*) Caudal bladder formed by endogenous budding; the head is surrounded, not only by the body of the worm and the caudal bladder, but also by the blastogen (proscolex). *Polycercus* (from the earthworm), *Monocercus* (from the black slug, *Arion*). (*b*) Caudal bladder formed by exogenous budding; the head is only surrounded by the body of the worm and the caudal bladder. *Cercocystis* (from *Tenebrio*), *Staphylocystis, Urocystis, Cryptocystis.*

Of these the most important are the first group, and regarding some of them a few words must be added. In the great majority of species only one tape-worm head is produced, and such bladder-worms constituted the genus *Cysticercus* of the older helminthologists. In certain cases, however, notably in the worm which produces the "staggers" of sheep, numerous heads are formed in the wall of each bladder; such larvæ formed the genus *Cœnurus*, but apart from their polycephalous condition there are no structural peculiarities calling for special notice. The third variety of bladder-worm (*Echinococcus*) is characterized by the fact that the tape-worm heads are not directly developed in the wall of the bladder itself, but from "brood capsules" which lie in numbers on the inner wall of the bladder.

Development of the Echinococcus.—The smallest bladder yet seen was reared by Leuckart in the pig, and consisted of a minute protoplasmic mass surrounded by a structureless cuticle. This cuticle thickens by deposition of new layers as growth proceeds, and the lamination of the cuticle is one of the characteristic peculiarities of the *Echinococcus*, another being the absence of an excretory system. At certain points in the parenchyma lining the cyst small warts are noticed (Fig. 2, D, *a*), which enlarge and become hollow; then the cavity enlarges in a direction opposite to the point of origin, and at the extremity of this hollow suckers and hooks are formed as in the case of *Cysticercus* described above (*b*, *c*). No sooner has the development of the first of these reached a certain degree of completeness than others are formed in similar fashion. The first part of the invagination takes place, by which the future head comes to lie within the brood-capsule and the pedicle is no longer hollow but solid (*e*); the suckers and hooks are, however, still invaginated, and remain so for a considerable period. Seeing that the interior of the brood-capsule is lined with cuticle, it corresponds to the outside of the parent cyst, and hence is probably the representative of a previous invagination. If this be so then the development of *Echinococcus* would be quite comparable with that of *Cysticercus*, the only difference being that, instead of the head being an invagination of the wall of the cyst itself, it is a secondary invagination, the primary being the brood-capsule. This does not, however, exhaust the peculiarities of the *Echinococcus;* the form just described, with a simple cyst and brood-capsules, is common in cattle, and hence goes by the name of *Echinococcus veterinorum;* but cases are frequent, and are the most common in the human subject, in which the cyst contains daughter-vesicles, differing from those just described in being sterile—giving rise to no heads. These daughter-bladders may originate in three different ways: (1) from little granular heaps, which are seen between the different layers of the cuticle, and which are probably derived primarily from the parenchymal layer,—since new layers of cuticle are continually formed internally, these bladders gradually make their way outwards, until they come to lie externally to the mother-vesicle (*Echinococcus exogena*, Kuhn; *E. scolecipariens*, Küchenmeister); (2) from brood-capsules; (3) from *Echinococcus*-heads; these last two modes of development give rise to vesicles, which are within the mother-vesicle, and produce a form which has been variously called *Echinococcus endogena*, Kuhn, *E. altricipariens*, Küchenmeister, and *E. hydatidosus*. A very remarkable form is *Echinococcus multilocularis*, which consists of a number of very small vesicles embedded in a common soft stroma; it is found exclusively in man, and for long was regarded as a form of alveolar cancer. The mode of its development is unknown (for further information, see Virchow, **17**). Compound bladders occur in man and the ox, whilst other ruminants, swine, and monkeys usually harbor the simple or exogenous forms. The organs most often affected are liver and lungs. The adult tape-worm (*T. echinococcus*) is found in the intestine of the dog, jackal, and wolf, occurring in considerable numbers between the villi. Its length (Fig. 3, A) is at most 5 mm. and it consists of only three or four segments; the head has four suckers and a double circlet of hooks.

Pathological Effects.

The pathological effects of Cestodes fall naturally into two categories: (1) those due to the adult worm, and (2) those due to the larvæ or bladder-worms.

(1) Those of the first group are in general slight, being confined to the abstraction of a certain amount of nutriment, and to a more or less acute feeling of irritation, sometimes amounting even to colic-like pains, in the intestine. There have indeed been many authorities who have maintained that they were beneficial; Jördens went so far as to describe them as the good angels and unfailing helpers of children, and Schimper records that the Abyssinians consider that they prevent constipation, and only regard them as disadvantageous when they grow too long. Notwithstanding all this, however, there are not a few cases on record in which anæmia and neurotic, or even mental, diseases have been caused by the malnutrition and irritation which they occasion.[2]

(2) The effects of Cestode larvæ may again be divided into two subdivisions. (*a*) That due to the invasion and wandering of a large brood of six-hooked embryos has been most successfully studied in cases in which animals have been fed for experimental purposes with fragments of ripe tape-worms; in such instances a train of symptoms has been observed to which the name "acute cestodic tuberculosis" has been given. It is characterized by loss of appetite, fatigue, ruffling of the hair, and fever; on post-mortem examination it has been found that the lymphatic system is in a state of inflammation, while the muscles present the appearance which has already been described. (*b*) The effects of formed bladder-worms may be summed up as dependent upon the pressure of the growing cyst and the consequent absorption of the surrounding tissues of the host, so that the importance of the results depends almost entirely upon the organ which is affected. Bladder-worms in the brain are, of course, the most frequently fatal, especially when, as is not unfrequently the case, they exert pressure upon the ganglia at its base. Küchenmeister has collected a considerable number of occurrences of cystic worms

---

[1] At the moment of going to press, Grassi (*Zeitschr. f. Parasitenk*, ii, 11) makes the important communication that *Tænia murina* (= *T. nana*) may develop without an intermediate host.

[2] The method of treatment for the removal of these tape-worms from the human body consists in the administration, first of purgatives, and thereafter of one or other of the following anthelmintics: turpentine, male fern (*Lastrea Filix-mas*), pomegranate or kousso,—of which the first two are the most reliable. Turpentine may be given in half-ounce doses along with castor oil, or made up into an emulsion with yolk of egg; while the male fern is usually administered in the form of liquid extract (half a drachm to one drachm). Careful search should be made in the evacuations for the head or scolex, without the expulsion of which there is no certain evidence that the parasite has been removed from the body.

in the brain; among these sixteen were not accompanied by pathological symptoms during life; in six others these were slight; twenty-four were cases of epilepsy, six of cramp, forty-two of paralysis, and twenty-three of mental disturbances of varying intensity. *Cysticerci* in the brain vary greatly in size and form according to the precise situation which they occupy; in its ventricles they have been found as large as a pigeon's egg. In the meshes of the arachnoid the bladder sometimes grows into a remarkably branched structure, which has been called *Cysticercus racemosus* by Zenker (**3**). Another peculiar form from the same organ has been described by Köberlé (**4**); it is characterized by the great length of its head-process (2 cm.), which is coiled up into a regular spiral of sometimes three turns; it has received the name *Cysticercus turbinatus*, though its specific distinctness is doubtful. The occurrence of *Cysticerci* in the eye is of special interest, because of the opportunity it affords of observing by means of the ophthalmoscope, the development of the worm in its natural environment. It seems generally to lie at first below the retina, and is visible as a bluish-white sharply defined body; subsequently the retina is destroyed by the pressure, and the worm falls forward into the vitreous body; sometimes the head may be seen protruding first through the opening; in the chambers of the eye the *Cysticercus* is almost always free, that is, without a capsule, and swimming in the fluid, so that its form and motions may be readily and accurately observed. A large number of cases of this affection have been recorded, principally by Von Graefe in Berlin (**5**), and in some the bladder has been successfully removed by operation.

The special symptoms of the *Echinococcus* vary, like those of other bladder-worms, with its situation and size: when it grows within cavities with more or less firm limits compression of adjoining vessels and glandular passages often results, producing œdema, varicose veins, congestion of various organs, or even dyspnœa, if the parasite occur in the thorax. The liver is its most frequent seat, and next the lung; but there is scarcely any organ of the body in which it has not been found, even the bones being sometimes affected. Since the expanding cyst grows in the direction of least resistance, it has a tendency to pass towards the surface of organs, and sometimes a cure is effected spontaneously by its rupturing into the alimentary canal or into some other passage leading to the exterior. Cases in which the cyst opens into the blood-vessels are almost always suddenly fatal. When the *Echinococcus* occurs near the surface of the body, it may be evacuated by puncture and a cure effected with but little risk.

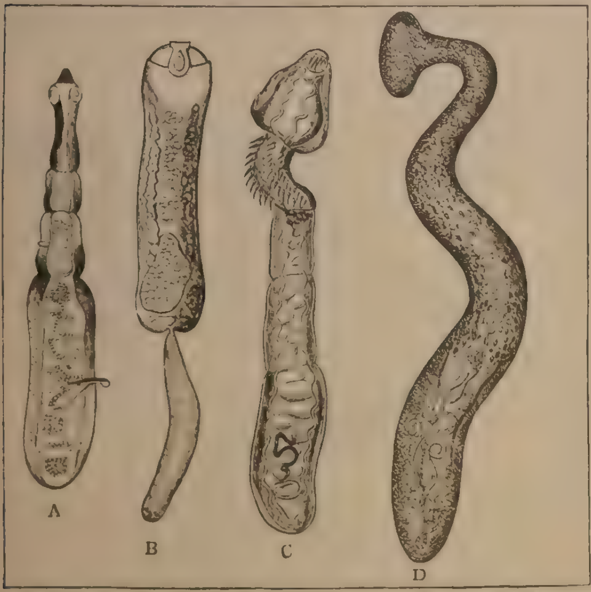

FIG. 3.—Various Forms of Tape-Worms. A, *Tænia echinococcus*; × 12 (from Leuckart). B, *Archigetes sieboldi*; × 60 (from Leuckart) C, *Echinobothrium typus*; × 10 (from Van Beneden). D, *Caryophyllæus mutabilis*; × about 5 (from Carus).

Systematic Arrangement of the Cestoda.

The following classification of the Cestodes, based mainly on that of Van Beneden, exhibits the present state of our knowledge of the group:

Class *Cestoda*.

Family I. *Amphilinidæ*.—Body oval, flattened, with a sucker at the anterior extremity; testes vesicular, vas deferens opening posteriorly; ovary (germarium) single, yolk-glands double, vagina opening near the vas deferens, uterus opening anteriorly; embryo ciliated in front and with ten hooks. Examples: *Amphilina*, Wagener (see below), *Amphiptyches*, Wagener.

Family II. *Caryophyllæidæ*.—Body unsegmented, flat, extended; head expanded, bilobed, and without hooks; a single set of sexual organs in the hinder portion; development probably a simplified metamorphosis. Example: *Caryophyllæus mutabilis*, from the intestines of Cyprinoid fishes (Fig. 3, D).

Family III. *Pseudophyllidæ*.—Head provided with two sucking grooves; proglottides not always well defined; a uterine aperture always present in addition to the openings of the vas deferens and vagina; embryo always (?) with a ciliated coat, and egg-shell with an operculum. Examples: *Bothriocephalus* (see below), *Triænophorus* (= *Tricuspidaria*), *Solenophorus*, *Schistocephalus*, *Ligula*, *Archigetes*, and perhaps *Duthiersia* (see below).

Family IV. *Diphyllidæ*.—Neck and two suckers armed with hooks. Example: *Echinobothrium*, two species known from Selachians, one immature from a mollusc (Fig. 3, C).

Family V. *Tetrarhynchidæ*.—Head provided with four suckers and four protractile proboscides armed with hooks; sexual openings marginal. Example: *Tetrarhynchus* (see below), about forty species known, many only described from immature forms.

Family VI. *Tetraphyllidæ*.—Head with four very mobile and distinct suckers, which are often armed with hooks or chitinous rods; body segmented, proglottides cast off when mature; sexual openings marginal.

Subfamily i. *Phyllobothrinæ*.—Suckers without hooks or spines. Examples: *Echeneibothrium*, *Phyllobothrium*, *Anthobothrium*, a few species of each, all from Elasmobranch fishes.

Subfamily ii. *Phyllacanthinæ*.—Suckers each with two to four hooks. Examples: *Calliobothrium*, *Onchobothrium*, *Acanthobothrium*, two or three species of each genus known from Selachians.

Family VII. *Tæniadæ*.—Head furnished with four suckers and often with a single or double circlet of hooks; proglottides well defined and cast off when mature; no uterine aperture. Example: *Tænia* (see below).

It seems advisable to add a few details regarding some of the forms alluded to in the above synopsis.

Amphilina foliacea, described as a Trematode by Rudolphi, is found in the body-cavity of the sturgeon. A number of unicellular glands open into the sucker, and are surrounded by the muscles of that organ; the nervous system consists of two ganglia, with a commissure, and two lateral nerves; the male organs resemble those of *Bothriocephalus*, the female those of the Trematodes; the family is generally regarded as furnishing a connecting link between the *Cestoda* and *Trematoda*; see Salensky (**18**) and Lang (**7**).

Bothriocephalus latus (**32**) is the most conspicuous example of the family *Pseudophyllidæ*, and is, moreover, noteworthy as being the largest tape-worm found in man; its length often reaches 8 to 9 metres, and its extreme breadth 10 to 12 mm. The head bears two grooves, which correspond in position with the flat sides of the body. There are two (more correctly three) genital openings, which are situated, not on the margin but on the flat side of the body, on that surface which is usually called the ventral. The most anterior of these is the male aperture (Fig. 4, A, *c.*), and immediately behind it is that of the vagina, (*v.o.*), so close that on superficial examination the two often seem to coincide. This vaginal opening, like that of the *Tæniadæ*, serves for the intromission of the penis and for the fertilization of the ova, but not for the exit of the ripe eggs; this being provided for by a special aperture at the other end of the uterus from that at which the eggs enter it. This uterine opening (*u.o.*) is situated at a short distance behind the other two. The result of this arrangement is that the eggs can be evacuated without any injury to the proglottis, and consequently their discharge commences before its separation from the parent worm and may continue for a long period. The uterus (*ut.*) itself, owing to its disposition in folded coils, when full of eggs, presents an irregular, round, lobular appearance, which has been compared to a flower or heraldic lily. The yolk-gland (*y.g.*) is widely disseminated in the lateral areas of the segments, and its ducts (*y.d.*) form a series of branching tubules, first described by Eschricht (**27**) under the name "yellow ducts." The excretory organs (*ex.*) differ from those of the *Tæniadæ* in that the canals exhibit a reticulate arrangement. The embryo (Fig. 4, D) as it leaves the egg is covered with a ciliated mantle, which corresponds to the firm egg-shell and associated membrane of the cystic tape-worms, and perhaps also to the ciliated envelope of certain Trematode larvæ (see TREMATODA). This ciliated organism swims freely about in the water, but after a time the six-hooked proscolex escapes from it. The next stage in its life-history is not yet known, but it has been recently shown by Braun of Dorpat (**33**) that at a subsequent stage it inhabits the pike and burbot, and develops into the sexual adult when transferred to the intestine of the human subject. The geographical distribution of *Bothriocephalus* is limited; it has been recorded with certainty in but few places outside Europe; while within that continent the coasts of the Baltic and Switzerland are the principal localities; it is widely distributed in Russia, and has been recorded from Poland, Denmark, Germany, as well as from France and Britain, though it is possible that the cases occurring in these latter countries have been due to importation.

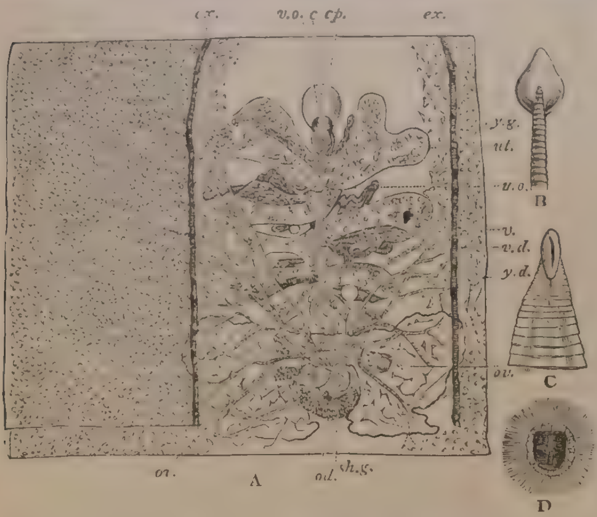

FIG. 4.—*Bothriocephalidæ.* A, A segment of *Bothriocephalus latus*, showing the generative organs from the ventral surface; *ex.*, excretory vessels; *c.*, cirrus; *c.p.*, cirrus pouch; *v.d.*, vas deferens; *v.o.*, vaginal opening; *v.*, vagina; *sh.g.*, shell-gland; *od.*, oviduct; *ov.*, ovary; *y.g.*, yolk-gland; *y.d.*, its duct; *ut.* uterus; *u.o.*, uterine opening; the testes are not visible from this side; × 23 (from Sommer and Landois). B, C, marginal and lateral views of the anterior part of *B. cordatus*, showing the cephalic grooves; × 5 (from Leuckart). D, Ciliated embryo of *B. latus*; × 60 (from Leuckart).

The genus *Ligula* has the segmentation obscure or indistinguishable. About six species are known. One is found encapsuled in a monkey, one in the common seal, others in reptiles and teleosteans. *Archigetes sieboldi* (Fig. 3, B) occurs in the body-cavity of an Oligochætous worm (*Tubifex rivulorum*); it is about 3 mm. long, and consists of an oval body (scolex), to which is attached a cylindrical tail (proscolex), bearing at the posterior extremity three pairs of hooks; both these parts are capable of motion. The scolex has eight longitudinal excretory canals, and a terminal vesicle; the ventrally situated genital aperture is the common exit of the vas deferens, the vagina, and a uterus separate from the latter; the development is direct, and it attains sexual maturity without a change of host. *Duthiersia*, Perrier (**34**), contains two species, both from the intestines of varanian lizards. The genus is characterized by the presence of two large compressed frilled suckers, separated by a septum and perforated at their bases. The proglottides have three genital apertures resembling those of *Bothriocephalus*.

The genus *Tetrarhynchus* was, a few years ago, made the subject of an elaborate memoir by Pintner (9), who investigated *T. longicollis*, V. Ben. The head, in which its most striking anatomical peculiarities are situated, really includes both the head and neck of previous authors (Fig. 5, A); it is some 9.94 mm. long, but only 0.75 mm. in diameter, and bears at its anterior end two obliquely placed oval disks (Fig. 5, B), each of which is perforated towards the apex by two round holes through which the four proboscides protrude. Each of these disks, moreover, shows traces of a division into two, a fact which indicates that it is formed by the fusion of two suckers corresponding to those commonly found in tape-worms. The flattening in this genus seems to be in a direction at right angles to that in which it usually takes place. The proboscides which are the most characteristic organs of the genus, are four in number, and protrude from or can be retracted into the anterior surface of the head. Each consists of three parts: (1) the toothed portion is the most anterior; it is shaped like a long narrow glove-finger, like which it is invaginable; on its external surface it bears rows of hooks, closely set in diagonal lines (Fig. 5, C); there are two forms of these: those which are directed outwards are large triangular hooks, with apices pointing backwards, whilst those situated on that surface of the proboscis which is turned towards the other proboscides are fine, delicate, and curved; between the hooks are fine chitinous hairs; (2) the membranous sheath is firmly attached where the general surface of the body passes over into the toothed portion around the orifice of the invagination; it consists of a thick homogeneous transparent skin, apparently an excretion of cells lining the cavity of the proboscis; (3) the muscular portion is the most posterior of all, and is composed of six layers, remarkable as containing striped muscular fibres; throughout all these three portions of the proboscis there extends a retractor muscle. The action of these various structures is not thoroughly understood, but it is probable that the proboscis is protruded by the action of the last-named muscular sheath, whilst it is retracted, after the relaxation of this, partly by the retractor muscle and partly by the pressure of the surrounding medium.

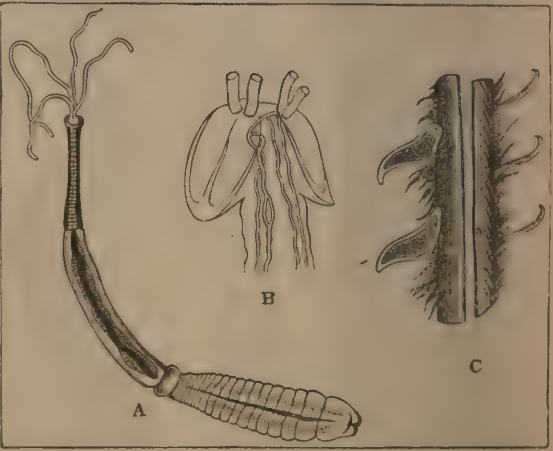

FIG. 5.—*Tetrarhynchus.* A, General view of the worm; × 4. B, head showing the suckers, proboscides and excretory canals; × 25. C, portion of a proboscis showing the two forms of hooks; highly magnified. (All from Pintner.)

The family *Tæniadæ* is usually described as containing only the one genus *Tænia*, but owing to the number and variety of its species, of which more than 350 have been described, it has been subdivided into groups, regarded by different authors as genera or subgenera. The subjoined arrangement is mainly that of Leuckart. It labors under the disadvantage that its chief divisions are based upon the bladder-worm or larval stage, which is only known in the case of comparatively few species.

- I. *Cystici* (cystic tape-worms).—Head rarely unarmed; usually provided with a rostellum and with one or more rows of hooks; proglottides longish, oval when mature; uterus with median stem and lateral branches; the larva has a caudal bladder containing fluid.
  - 1. *Cystotænia*, Leuckart.—The head arises in the wall of the embryonic bladder.
    - *a*. *Tænia saginata*, Göze.—Without hooks (= *T. mediocanellata*, Küchenmeister, = genus *Tæniarhynchus*, Weinland).
    - *b*. *Tænia solium*, Rudolphi.—Head with a double circlet of hooks.
    - *c*. *Tænia acanthotrias*, Weinland.—Head with a triple circlet of hooks (= genus *Acanthotrias*. Weinland).
  - 2. *Echinococcifer*, Weinland.—The heads arise in special brood-capsules. *Tænia echinococcus*, V. Siebold.
- II. *Cystoidei* (ordinary tape-worms).—The larva has no distended caudal bladder containing fluid.
  - 1. *Hymenolepis*, Weinland.—Proboscis with a single row of small hooks. *Tænia nana*, V. Siebold, *T, flavopunctata*, Weinland.
  - 2. *Dipylidium*, Leuckart.—Head with several rows of hooks, each with a discoidal base; a right and left set of genital organs in each joint, the uterus, however, being single and common to the two. *Tænia cucumerina*, Rudolphi (= *T. elliptica*, Batsch).

Hamann (**2**) has recently proposed a new genus, *Ptychophysa*, for *Tænia lineata*, Göze, which is defined by the following characters: (1) the porus genitalis is on the surface and not on the margin of the joints: (2) the vaginal opening is anterior to that of the cirrus; (3) at a certain period the uterus is convoluted; (4) there is a peculiar shell-gland. In many of these characters the species shows a resemblance to the *Bothriocephalidæ*.

Occurrence in Man.—The Cestodes which in the adult state infest man, with their corresponding larvæ and temporary hosts, are as follows:

Tænia saginata.	*Cysticercus bovis.*	Ox.
T. solium.	*C. cellulosæ.*	Pig, man.
T. nana.	(?)	(?)
T. flavopunctata.	(?)	(?)
T. madagascariensis.	(?)	(?)
T. cucumerina.	*C. T. cucumerinæ.*	*Trichodectes canis.*
Bothriocephalus latus.		Pike, burbot.
B. cristatus.		(?)
B. cordatus.		Fish (?)

Other species, however, inhabit the human body in their larval condition; a list of them, with the corresponding adult forms and permanent hosts is subjoined:

Cysticercus cellulosæ.	*Tænia solium.*	Man.
C. acanthotrias.	*T. acanthotrias* (incog.)	(?)
C. tenuicollis.	*T. marginata.*	Dog, wolf.
Echinococcus.	*T. echinococcus.*	Dog.

Phylogeny.—There can be no doubt that the Cestodes and Trematodes are intimately related and have sprung from a common ancestor; there are so many structural peculiarities in which they agree (compare TREMATODES), and they are connected by so many intermediate forms, that their affinity can admit of no doubt. According to Leuckart, the original ancestor of both was probably allied to the Planarians, while Huxley (**22**, pp. 213, 676) points out that it is at all events possible that they have no connection with free forms but have always been anenterous, and in fact are nothing but "gigantic morulæ, so to speak, which have never passed through the gastrula stage."

TAPIOCA is a farinaceous food-substance prepared from cassava starch, the product of the large tuberous roots of the cassava or manioc plant, *Manihot utillissima* (*Jatropha manihot*), native of Brazil (see CASSAVA, vol. v. p. 159, and comp. ARROWROOT, vol. ii. p. 552, Fig. 6). Cassava starch, being separated from the fibrous and nitrogenous constituents of the roots, is in a moist condition spread upon iron plates, and with constant stirring exposed to such heat as causes a partial rupture of the starch granules, which agglomerate into irregular pellets, becoming hard and translucent when cooled. In this partly torrefied condition the starch forms the tapioca of commerce, a light, pleasant, and digestible food, much used in puddings and as a thickener for soups. The French prepare an artificial tapioca from potato starch, mixed with various vegetable substances, for use in soups, etc., which is found in the market under such names as tapioca Crecy, tapioca Julienne, etc., according to the dried vegetables with which the preparations are made.

TAPIR. The general characters of the animals of the perissodactyle or odd-toed section of the hoofed mammals are described under MAMMALIA, vol. xv. pp. 433–4. This once numerous group is at present represented by only three rather isolated families, the Horses, Rhinoceroses, and Tapirs. The last of these have retained much more of the original characters of the primitive Ungulates of the Eocene period than the others, and have indeed remained practically almost unchanged since the Miocene period, while almost all other mammalian forms which existed then have either become extinct or undergone extensive modification. The tapirs constitute the single genus, *Tapirus*, of the family *Tapiridæ*.

The dentition is *i* $\frac{3}{3}$, *c* $\frac{1}{1}$, *p* $\frac{4}{3}$, *m* $\frac{3}{3}$; total 42. Of the upper incisors, the first and second are nearly equal, with short, broad crowns, the third is large and conical, considerably larger than the true canine, which is separated from it by an interval. Lower incisors diminishing in size from the first to the third; the canine, which is in contact with the third incisor, large and conical, working against (and behind) the canine-like third upper incisor. In both jaws there is a long interspace between the canines and the commencement of the teeth of the molar series, which are all in contact. First upper premolar with a triangular crown, narrow in front owing to the absence of the anterior inner cusp. The other upper premolars and molars all formed on the same plan and of nearly the same size, with four roots and quadrate crowns, rather wider transversely than from before backwards, each having four cusps, connected by a pair of transverse ridges, anterior and posterior. The first lower premolar compressed in front; the others composed of a single pair of transverse crests, with a small anterior and posterior cingular ridge.

Skull elevated and compressed. Orbit and temporal fossa widely continuous, there being no true post-orbital process from the frontal bone. Anterior narial apertures very large, and extending high on the face between the orbits; nasal bone short, elevated, triangular, and pointed in front. Vertebræ: C 7, D 18, L 5, S 6, C about 12. Limbs short and stout. Fore feet with four toes, having distinct hoofs: the first is absent, the third the longest, the second and fourth nearly equal, the fifth the shortest and scarcely reaching the ground in the ordinary standing position. Hind feet with the typical perissodactyle arrangement of three toes,—the middle one being the largest, the two others nearly equal. Nose and upper lip elongated into a flexible, mobile snout or short proboscis, near the end of which the nostrils are situated. Eyes rather small. Ears of moderate size, ovate, erect. Tail very short. Skin thick and but scantily covered with hair.

The existing species of tapir may be grouped into two sections, the distinctive characters of which are only recognizable in the skeleton. (A) With a great anterior prolongation of the ossification of the nasal septum (mesethmoid), extending in the adult far beyond the nasal bones, and supported and embraced at the base by ascending plates from the maxillæ (genus *Elasmognathus*, Gill). Two species, both from Central America, *Tapirus bairdi* and *T. dowi*. The former is found in Mexico, Honduras, Nicaragua, Costa Rica, and Panama; the latter in Guatemala, Nicaragua, and Costa Rica. (B) With ossification of the septum not extending farther forward than the nasal bones (*Tapirus* proper). Three species, *T. indicus*, the largest of the genus, from the Malay Peninsula (as far north as Tavoy and Mergui), Sumatra, and Borneo, distinguished by its peculiar coloration, the head, neck, fore and hind limbs being glossy black, and the intermediate part of the body white; *T. americanus* (*T. terrestris*, Linn.), the common tapir of the forests and lowlands of Brazil and Paraguay; and *T. roulini*, the Pinchaque tapir of the high regions of the Andes. All the American species are of a nearly uniform dark brown or blackish color when adult; but it is a curious circumstance that when young (and in this the Malay species conforms with the others) they are conspicuously marked with spots and longitudinal stripes of white or fawn color on a darker ground.

American Tapir, from a living specimen in the London Zoological Gardens.

The habits of all the kinds of tapirs appear to be very similar. They are solitary, nocturnal, shy, and inoffensive, chiefly frequenting the depths of shady forests and the neighborhood of water, to which they frequently resort for the purpose of bathing, and in which they often take refuge when pursued. They feed on various vegetable substances, as shoots of trees and bushes, buds, and leaves. They are hunted by the natives of the lands in which they live for the sake of their hides and flesh.

The singular fact of the existence of so closely allied animals as the Malayan and the American tapirs in such distant regions of the earth and in no intervening places is accounted for by what is known of the geological history of the race, for, if we may judge from the somewhat scanty remains which have been preserved to our times, consisting chiefly of teeth, the tapirs must once have had a very wide distribution. There is no proof of their having lived in the Eocene epoch, but in deposits of Miocene and Pliocene date remains undistinguishable generically and perhaps specifically from the modern tapirs (though named *T. priscus*, *T. arvernensis*, etc.) have been found in France, Germany, and in the red crag of Suffolk. Tapirs appear, however, to have become extinct in Europe before the Pleistocene period, as none of their bones or teeth have been found in any of the caves or alluvial deposits in which those of elephants, rhinoceroses, and hippopotamuses occur in abundance; but in other regions their distribution at this age was far wider than at present, as they are known to have extended eastward to China (*T. sinensis*, Owen) and westwards over the greater part of the southern United States of America, from South Carolina to California. Lund also distinguished two species or varieties from the caves of Brazil. Thus we have no difficulty in tracing the common origin in the Miocene tapirs of Europe of the now widely separated American and Asiatic species. It is, moreover, interesting to observe how very slight an amount of variation has taken place in forms isolated during such an enormous period of time.

(W. H. F.)

TAR is a product of the destructive distillation of organic substances. It is a highly complex material, varying in its composition according to the nature of the body from which it is distilled,—different products, moreover, being obtained according to the temperature at which the process of distillation is carried on. As commercial products there are two principal classes of tar in use—(1) wood tar, the product of the special distillation of several varieties of wood, and (2) coal tar, which is primarily a bye-product of the distillation of coal for the manufacture of illuminating gas. These tars are intimately related to the bitumen, asphalt, mineral pitch, and petroleum obtained in very many localities throughout the world.

Wood Tar.—Wood tar, known also as Stockholm and as Archangel tar, is principally prepared in the great pine forests of central and northern Russia, Finland, and Sweden. The material chiefly employed is the resinous stools and roots of the Scotch fir (*Pinus sylvestris*) and the Siberian larch (*Larix sibirica*), with other less common fir-tree roots. A large amount of tar is also prepared from the roots of the swamp pine (*P. australis*) in North and South Carolina, Georgia, and Alabama, in the United States. In the distillation of wood a series of products, including gas, tar, pyroligneous acid and wood spirit, and charcoal may be obtained, and any of these may be the primary object of the operation. When tar is the substance sought, the ancient and crude method of working is yet largely adopted in the north of Europe. The wood to be treated is closely piled up into a huge conical stack or pile on an elevated platform, the sole of which is covered with clay and tiles. The sole slopes inwards from every side to the centre, where an opening communicates with a vaulted cavity under the elevated platform. The pile of wood is closely covered over with layers of turf and earth or sand to a depth of several inches, but leaving at first near the bottom numerous apertures for the admission of air to promote ignition. The pile is ignited from below, and as the fire spreads through the heap the various apertures are closed up and a slow smouldering combustion goes on for some days till, by the sinking of the pile, the top of the stack falls in, and a bright flame springs up at that point. About ten days after ignition tar first begins to flow, and it is at once collected into barrels. According to the size of the pile, the distillation may continue several weeks, the tar secured amounting to about 17.5 per cent. of the wood operated on. In this method several valuable products—the gas, the crude pyroligneous acid, and much charcoal—are lost or wasted; and a more economical process of treating the wood in closed stills or retorts is now largely used in Russia, the gas evolved serving as fuel under the retorts. The heavier tar products of the distillation collect at the bottom of the retort, whence they are carried off by a pipe to a receiver; the volatile portion passes off at the upper part of the retort, and is separately condensed, the lightest portion passing through a worm condenser. From treatment in close retorts resinous roots yield from 16 to 20 per cent. of tar, with some oil of turpentine and pyroligneous acid.

Wood tar is a semi-fluid substance, of a dark brown or black color, with a strong pungent odor and a sharp taste. Owing to the presence of acetic (pyroligneous) acid, which is a collateral product, it has an acid reaction; it is soluble in that acid, as well as in alcohol and the fixed and essential oils, etc. Tar consists essentially of a mixture of homologous hydrocarbons, and by redistillation it can be fractionated into a series of bodies having fixed boiling points. Some varieties of tar have a granular appearance, from the presence of minute crystals of pyrocatechin, which dissolve and disappear on heating the substance. Pyrocatechin dissolves freely in water, and to it the tar water (*liquor picis*) of pharmacy probably owes its value.

Crude tar from retorts, when submitted to redistillation, gives off wood spirit (methyl-alcohol), and then acetic (pyroligneous) acid, and finally on forcing the heat, pitch oil is driven off. The residuum left in the still hardens into a solid vitreous mass, which forms the black pitch of commerce. Tar and pitch are most largely used as protective coatings for woodwork and other materials much exposed to water and the weather. Thus tar is of great value in connection with shipbuilding and shipping generally. A considerable quantity is used in manufacturing tarred ropes, and in the "smearing" of highland sheep to afford a protection against the weather. Pitch also is the basis of the Berlin black or Brunswick black used for coating cast-iron goods and for "japanning" preparations.

Coal Tar.—The art of distilling coal for the production of tar was discovered and patented by the earl of Dundonald in 1787, and till the general introduction of coal gas some amount of coal was yearly distilled in Scotland for the production of coal tar. The demand for the substance was limited, it being principally used for coating iron castings and smith work, for making an inferior lamp-black, and as a source of a solvent oil. With the extensive use of coal gas the necessity for this separate distillation ceased, and soon tar was produced in the manufacture of gas in quantities that could not be disposed of. It was burned up for heating gas-retorts; it was mixed with coal dust, sawdust, etc., for making patent fuel; and it was distilled for producing a series of hydrocarbon oils, heavy tar, and pitch; but it was only after the discovery and introduction of "tar-colors" that the substance came for some time to be really valuable. Since that time its price has fluctuated greatly; and in the United Kingdom alone there are now distilled annually about 10,000,000 tons of coal for gas-making, producing 120,000,000 gallons of crude tar,—a quantity greatly in excess of the ordinary demand.

If wood be distilled slowly at low temperatures, the gases consist chiefly of carbonic oxide and carbonic acid, mixed with only very little of carburetted hydrogens, and consequently little luminous on combustion; the watery part of the tar includes relatively much of methyl-alcohol, acetone, and acetic acid; the oily part of the tar (tar proper) has a certain proximate composition characteristic of this mode of distillation. Our present knowledge in regard to this last-named point is very incomplete; of definite species the following have been discovered:

(1) Phenol, $C_6H_5.OH$ (synonym carbolic acid).
(2) Cresol, $(C_6H_4.CH_3)OH$.
(3) Phlorol, $(C_6H_4.OH)C_2H_5$.
(4) Pyrocatechine, $(C_6H_4)(OH)_2$, one of three isomerides.
(5) Guaiacol, $C_6H_4\left\{\begin{matrix}OH\\OCH_3\end{matrix}\right.$, methyl-ester of No. 4.
(6) Homo-pyrocatechine, $\left\{C_6H_3(CH_3)\right\}(OH)_2$.
(7) Creosol, $\left\{C_6H_3(CH_3)\right\}\begin{matrix}OH\\OCH_3\end{matrix}$, methyl-ester of No. 6.

Genuine creosote consists of (1), (2), (5), and (7). In addition, there are numberless bodies which still await scientific definition.

If the distillation of wood is carried out at a very high temperature,—if, for instance, the wood is placed in a relatively large retort previously brought up to a bright red heat and kept at such temperature, or if the vapors produced at a relatively low temperature are passed through intensely heated pipes before reaching the condenser (Pettenkofer's method for producing illuminating gas from wood),—the gas produced contains a considerable admixture of luminiferous hydrocarbons, the proportions of methyl-alcohol, acetone, and acetic acid get less, and the tar proper assumes more of the character of coal-gas tar (see below). Similar observations we make in the case of coal. About 1862 Wigan cannel coal used to be distilled industrially at low temperatures to produce "light oils." Schorlemmer examined these and found them to consist chiefly of "paraffins" (see PARAFFIN) from C_5H_{12} upwards. A similar result is obtained with ordinary coal, although in its case the "benzols" are more largely represented. If we distil any kind of coal at high temperatures—*i.e.*, in the way customary for illuminating-gas making—the distillable part of the tar proper consists chiefly of benzene, C_6H_6, and benzene-derivatives, *i.e.*, benzols, $C_6H_6 + nCH_2$; phenols, C_6H_6O, and homologues, $(C_6H_5.nCH_2,OH$; amido-bodies, $C_6H_5NH_2$ (aniline), and homologues; condensed benzols, such as napthalene $C_{10}H_8 = 2C_6H_6 - C_2H_4$; anthracene, $C_{14}H_{10} = 3C_6H_6 - C_4H_8$; chrysene, $C_{18}H_{12} = 4C_6H_6 - C_6H_{12}$, etc. The paraffins then become an altogether subordinate feature.

A great and meritorious research of Berthelot's has thrown considerable light on the chemical mechanism of dry distillation. As found by him, even the most complex of the substances named are producible by the interaction upon one another of a few bodies of very simple constitution, or even one or other of these by the mere action of a high temperature. To give a few examples: Marsh-gas, CH_4, when passed through red-hot tubes, yields olefines, C_2H_4, C_3H_6, C_4H_8, etc., with elimination of hydrogen, H_2. The same CH_4, if subjected to a spark-current (*i.e.*, local application of intense heat), yields acetylene and hydrogen, $2CH_4 = C_2H_2 + 3H_2$, and the acetylene produced passes partly into benzene, $C_6H_6 = 3C_2H_2$. Ethylene, C_2H_4, when passed through a porcelain tube kept at a moderate red heat, yields benzene, C_6H_6, styrolene = phenyl-ethylene, $C_2H_3.C_6H_5$, naphthalene, $C_{10}H_8$, and perhaps also its hydride, $C_{10}H_{10}$. Acetylene, *qua* potential benzene, and ethylene yield styrolene and hydrogen, $C_6H_6 + C_2H_4 = C_6H_5.C_2H_3 + H_2$; and styrolene plus ethylene yields hydrogen and naphthalene, $C_{10}H_8$.

Benzol at a high temperature loses hydrogen, and, so to say, doubles up into di-phenyl, $C_{12}H_{10}$; and this latter, when heated with ethylene, yields anthracene, $C_{14}H_{10}$, and hydrogen, $C_{12}H_{10} + C_2H_4 = C_{14}H_{10} + 2H_2$. Conversely, hydrogen may, so to say, turn out its equivalent of a hydrocarbon; thus, for instance, chrysene, $C_{18}H_{12} + 2H_2$, yields di-phenyl, $C_{12}H_{10}$ + benzene, C_6H_6.

Pyrogenic reactions generally are reversible; thus, any of the following three equations is correct, whether we read it from the left to the right or from the right to the left:

(1) C_2H_6 (ethane), at a red heat becomes $C_2H_4 + H_2$.
(2) $C_{12}H_{10} + C_6H_6 = C_{18}H_{12} + 2H_2$.
(3) $C_{14}H_{10} + 2H_2 = 2C_6H_6 + C_2H_2$.

Hence no single pyrogenic reaction goes to the end; if it does not, so to say, check its own progress, other secondary reactions set in and do so, the general result being that ultimately, but in general slowly, a state of dynamic equilibrium is attained in which a set of synthetic reactions on the one hand and a set of analytic reactions on the other compensate one another.

Industrial Working of Coal Tar.[1] — Coal tar, as it comes from the gas-works, is used for a variety of purposes, such as—(1) for fuel, the tar being made into a spray by means of a steam-injector and the spray kindled; (2) for the preservation of building materials, porous stones, and bricks, etc.; (3) for making roofing-felt (in 1868 five-sixths of the 9000 tons of tar produced at the Berlin gas-works was thus utilized; the case, however, is different now); (4) for making a low quality of lamp-black. At present, however, most of the tar produced, in centres of industry at least, is worked up by distillation. The tar as it comes from the gas-works is allowed to rest in a "pond" until the tar-water (solution chiefly of ammonia and certain ammonia salts) has gone to the top. The tar proper is then pumped into a large wrought-iron still (of upright-cylinder form preferably) and therein subjected to distillation over a naked fire. A necessary preliminary, however, is the removal of the unavoidable remnant of water, which is best effected by cautiously heating the tar in the still so as to render it more fluid and enable the water to rise to the top and then letting the upper stratum run out by an overflow tap at the side. The distillation is then started. It involves the formation of two sets of volatile products, namely: (1) combustible gases (including sulphuretted hydrogen and bisulphide of carbon vapor), which must be led away to avoid nuisance and danger of fire, and (2) a very complex liquid or semi-liquid distillate. This latter is collected in successive fractions, generally in this manner: (1) as "first runnings," what comes over at temperatures below 105° to 110° C. [221° to 230° F.]; (2) as "light oils," at temperatures between 110° and 210° C. [230° to 410° F.]; (3) as "carbolic oil," at temperatures between 210° to 240° C. [410° to 464° F.]; (4) as "creosote oil," at temperatures between 240° to 270° C. [464° to 518° F.]; (5) as anthracene oil, at temperatures above 270° C. [518° F.].

---

[1] For wood tar, see WOOD SPIRIT and VINEGAR.

In the earlier part of the "first runnings" and light-oil period the condenser must be kept cold; towards the end it must be kept warm to prevent choking by solidified naphthalene. In practice, the operator does not go entirely by the boiling point, but to a great extent by the specific gravity of the distillate, which, in general, increases as the boiling point rises. As soon as a drop of the last runnings floats in water (exhibits the specific gravity 1), the "light oil" is supposed to be over. That the fractionation is not always and everywhere effected in the same way needs hardly be said. If the manufacture of carbolic acid is aimed at, it is best (according to Lunge) to select the fraction 170° to 230° C. [338° to 446° F.] for this purpose. Naphthalene boils as high as 217° [422° F.], yet a deal goes into this carbolic-acid fraction. As soon as naphthalene begins to crystallize out largely (on cooling down a sample of distillate), the carbolic acid may be presumed to be over. What follows next is put aside as creosote oil, until, after the disappearance of the naphthalene, a new solid product, namely, anthracene, begins to show itself. With any tar that contains a remunerative proportion of anthracene, the anthracene oil is the most valuable of the products, as the raw material for the making of artificial alizarins.

Supposing the anthracene to have been extracted as completely as practicable, the residue in the still consists of "hard pitch," a viscid black fluid which on cooling freezes into a fragile solid. In former times more commonly than now "soft pitch" used to be produced by leaving more or less of the anthracene oil and even creosote oil in the still. At the end of the anthracene stage of the distillation it is as well, if not necessary, to help the very high boiling vapor out of the still by means of superheated steam, and to keep the worm at 100° C. [212° F.] to prevent choking. At a German establishment a vacuum is used with great advantage.

We come now to explain briefly how the several fractions are worked up.

The pitch (which we assume to be "hard pitch") must be run off hot through a tap at the bottom of the still and led into a low-roofed and well closed-in "house," because it would take fire in the open air. After it has cooled down sufficiently in the "house," the pitch is run into pitch-holes in front of the house and allowed to freeze there. The depth of pitch in a hole is about 12 inches. The solid pitch is hacked out with pickaxes and sent into commerce. A superior apparatus for the recovery of the pitch, which precludes all danger of conflagration and many inconveniences of the ordinary system, has been devised for the Paris gas-works by Regnault.[1] Lunge found, from many distillations, that tar from the midland counties yields about 55 per cent. of hard pitch.

Hard pitch is used chiefly for making the following. (1) *Asphalt.*—The pitch is fused up—perhaps in the still which produced it—with the requisite proportion of creosote and anthracene oil, previously freed from their valuable components. Such asphalt is used for street paving, *i.e.*, filling up the spaces between the paving-stones, and, in admixture with sand and generally more or less of natural asphalt, for the making of footpaths and floorings generally. In Germany it serves for the making of pipes for conveying acid liquids in works and chemical laboratories, etc. Endless hemp-paper is soaked in liquefied asphalt and wound spirally around an iron core, previously smeared over with soft soap, in about 100 layers. The whole is then exposed to strong pressure while still hot, and is separated from the core after being allowed to cool. Such pipes stand almost any kind of acid, but they must not be used for hot liquids. (2) *Varnishes.*—The pitch is dissolved in suitable tar oils,—creosote oil for a lower and light oil for a higher quality. (3) *Coke.*—In former times more frequently than now pitch was made into coke by transferring it to a special flat still and distilling as long as any volatile products came off. The coke which remains is a very pure and consequently valuable fuel. (4) *Lamp-black* (as a last resource, if no other mode of utilization is practicable).—The pitch is subjected to partial combustion on hot iron plates and the smoke conveyed into chambers to deposit its carbon. The yield is about 40 per cent.

Anthracene Oil.—The oil is allowed to stand cold for a week or so until the anthracene has crystallized out as completely as possible. The mother-liquor is then eliminated, the bulk by means of a filter-press, the rest, at a higher than the ordinary temperature, by hydraulic pressure. The crude product includes far more than half its weight of impurities—phenanthrene, paraffin, naphthalene, etc. To remove these as far as possible, the crude anthracene is ground up and treated with petroleum spirit (boiling at 70° to 100° C. [158° to 212° F.]) or coal tar naphtha (120° to 190° C. [248° to 374° F.]), in which real anthracene is relatively insoluble. The insoluble part is separated by filtering arrangements and presses (so constructed as to avoid danger of fire), and at last sublimed, more with the view of bringing it into a customary convenient form than with the object of effecting further purification. Such final anthracene may contain 50 to 65 per cent. of pure substance. The only reliable method for determining its strength is to convert a known weight into anthraquinone, $C_{14}H_{10}O_2$, by boiling it with a glacial acetic acid solution of chromic acid, separating out the quinone by diluting with water, collecting and weighing the product. One part of quinone corresponds to 0.8558 of anthracene.

Creosote Oil is either used as it is for pickling timber, softening of pitch, etc., or else redistilled to extract from it what there is of anthracene oil and carbolic acid oil, which are worked up with the respective principal quantities.

Carbolic Oil.—Assuming this oil to have been collected (as it should be if intended for the making of carbolic acid) between 170° and 230° [338° and 446° F.], the process of extraction is, briefly, as follows: The oil is mixed with a suitable proportion of caustic-soda lye (ascertained by an assay) in an iron vessel at 40° to 50° C. [104° to 122° F.]. Charles Lowe recommends lye of 1.34 sp. gr., diluted with water to five times its volume. After settling, the aqueous layer is withdrawn into a lead-lined vessel, and the soda supersaturated by sulphuric acid. Crude carbolic acid rises to the top as an oil, and is withdrawn to be sold as such or purified. See CARBOLIC ACID.

Naphthalene abounds in the oil left after extraction of the carbolic acid by caustic soda and in the more volatile fractions of the creosote oil. From these it separates out (not completely), on standing, in crystals. These are collected best in a filter-press, and then subjected to hydraulic pressure to force out the rest of the mother-liquor. The crude naphthalene thus obtained contains an impurity which causes it to become red on standing in the air. To remove it, the crude product is mixed with 5 to 10 per cent. of vitriol of at least 1.7 sp. gr., at a moderate heat (addition of a little binoxide of manganese is an improvement, Lunge); it is then washed, first with water, then with dilute alkali, and lastly again with water, to be ultimately distilled or sublimed. In the latter case it is obtained in the form of thin colorless plates of great beauty. It fuses at 80° C. [176° F.] and boils at 217° C. [423° F.]. Naphthalene is used largely in the making of certain tar colors, such as Manchester yellow, $C_{10}H_6(NO_2)_2$, and the beautiful scarlets and crimsons made by the "farbwerke" in Höchst, Germany; these latter are diazo-compounds derived from β-naphthol, $C_{10}H_7 OH$). Coal gas, if impregnated at a suitable temperature with naphthalene vapor immediately before issuing from the burner, gains greatly in luminosity. This is the principle of the "albo-carbon" gas lamps.

First Runnings and Light Oil.—These may be said to include all the industrially valuable "benzols" (taking "benzol" as a generic term for benzol or benzine itself and its higher homologues, C_6H_6, C_7H_8, C_8H_{10}, etc.). As the distiller in most cases does not aim at an actual separation of all the individual benzols from one another, but at the production of certain benzol mixtures demanded by the trade, the mode of working may assume a great variety of forms; yet the first aim in all cases is the same, being the elimination of all the *non*-benzol from the given oil or oils. For this purpose the light oil is, as a rule, subjected to a preliminary fractionation over a naked fire to split it up into fractions fit to be worked for (crude) benzol (C_6H_6 and C_7H_8, for carbolic acid (C_6H_6O), and to be incorporated with the creosote oil respectively; the carbolic acid is extracted, and the creosote-oil part put aside, and thus one or more mixtures of "benzols" are obtained.

The first runnings contain the bulk of the benzine, C_6H_6, and a little of its higher homologues, associated, however, with bisulphide of carbon, low-boiling olefines, C_nH_{2n}, traces of carbolic acid, etc. To remove these impurities as far as possible, the oil is thoroughly agitated with concentrated oil of vitriol (which takes up the impurities except the bisulphide of carbon), and the "dirty" acid allowed to settle out. The acid is then withdrawn as neatly as possible, and the residual oil washed, first with water, then with dilute caustic soda, and, lastly, again with pure water. The washed oil then is subjected to a preliminary fractionation by distillation over a naked flame in the "crude benzol still."

---

[1] It is described in Lunge's *Treatise on the Distillation of Coal Tar*, London, 1882, to which this article is largely indebted.

The several mixed benzols obtained are subjected finally to a further fractionation in stills worked with steam, to be divided into mixed products known by specific names in commerce. But these we cannot possibly consider here. We will rather give an idea of the way in which the several chemical species (benzene, toluene, etc.) are being isolated in a state of approximate purity to meet the demands of the tar-color industry. To do so even for one named component by means of ordinary stills would require an endless number of fractional distillations. The work is very materially shortened if, as proposed by Mansfield long ago, we combine the still with an inverted condenser (still-head, dephlegmator), inserted between the still and the worm, and keep that intermediate condenser at a suitable constant temperature, so that all the less volatile part of the vapor is recondensed and sent back to the still. An excellent apparatus of this kind was constructed and worked successfully by Coupier. His apparatus consists of three parts, viz.: (1) a still heated by means of a coil of close steam pipes; (2) a columnar rectifier—"colonnen-apparat," as the Germans call it,—which communicates with the still, and which is divided into many compartments by horizontal septa so contrived that the vapor in passing from a compartment to the next higher one must bubble through the liquid condensed there from preceding vapor,—an overflow pipe, trapped below by condensate, hindering accumulation of the liquid in any compartment beyond a certain level; (3) a constant temperature still-head, consisting of a succession of communicating ring-shaped tubes, which are immersed in a bath of water or molten paraffin kept at a prescribed constant temperature. Only the most volatile part of the vapor survives as such in the columnar rectifier, the degree of its volatility depending, of course, other things being equal, on the rate at which we distil. This most volatile part suffers partial condensation at the prescribed temperature in the still-head; the condensed parts are sent back to compartments of the "column" by pipes bent into the shape of a U at the point where they join the "column" so as to prevent vapor from entering them. The uncondensed vapor goes to the worm, and is condensed as usual.

To prepare benzine, the still-head is kept at 60° to 70° C. [140° to 158° F.] At first a mixture of low-boiling bodies and benzine goes over, which is rejected, but soon pure benzol follows and continues until almost all this component has distilled over. The benzol obtained boils between 80° and 82° C. [176° and 180° F.], and consequently is practically pure. In order now to extract the toluene, C_7H_8, we raise the temperature of the still-head to 100° C. [212° F.]. A small quantity of a mixture of benzene and toluene follows, which is rejected. After it comes a continuous distillation of almost pure toluene, boiling at 110° to 112° C. [230° to 234° F.]. In a similar manner (relatively) pure xylene, C_8H_{10}, boiling point 137° to 140° [278° to 284° F.], and trimethyl-benzene, C_9H_{12}, boiling point 148° to 150° [298° to 302° F.], can be extracted successively; but the process becomes troublesome with anything above toluene on account of the high temperatures involved for still and still-head. Coupier's apparatus is now superseded by other constructions, but they all work on the same principle,—that of the Coffey still, as used for the rectifying of spirit of wine.

Pure benzene, toluene, and xylene are used largely for the manufacture of tar-colors. The following (and other) mixtures are produced directly from the light oil or first runnings:

(1) 90 per cent. benzol	initial boiling point		82° C.	[180° F.]
(2) 50 per cent. benzol	"	"	88	[190 F.]
(3) "Toluol"	"	"	100	[212 F.]
(4) Carburetting naphtha	"	"	108	[226 F.]
(5) Solvent naphtha	"	"	110	[230 F.]
(6) Burning naphtha	"	"	138	[280 F.]

No. 4 serves for enriching coal-gas and adding to its luminiferous power, No. 5 for varnishes, No. 6 for feeding primitive lamps used in the open air, where smoke is no objection.

The following percentage table for the tar from the Berlin gas works (given in *Chemische Industrie* for 1879) gives an idea of the quantitative composition of this most complex material:

Benzol (including toluol, etc.)	0.80	
Higher benzols	0.60	
Crystallized carbolic acid	0.20	
Creosol for disinfecting purposes	0.30	
Naphthalene	3.70	
		5.60
Creosote oil		24.00
Anthracene (pure)		0.20
Pitch		55.00
Water and loss		15.20

(J. PA.—W. D.)

TARAI, a British district in the Kumáun division of the lieutenant-governorship of the North-West Provinces and Oudh, India, lying between 28° 51′ and 29° 30′ N. lat. and 78° 46′ and 79° 47′ E. long. It contains an area of 938 square miles, and is bounded on the N. by the Khumáun Bhábar, on the E. by Nepál and Pilibhit subdivision of Bareilly district, on the S. by the districts of Bareilly and Moradábád and the native state of Rámpur, and on the W. by Bijnaur. The headquarters of the district are at Naini Tal. Tarai ("moist land") consists of a long narrow strip of country running for about 90 miles east and west along the foot of the Himalayas, with an average breadth of about 12 miles. At its northern edge, where the waterless forest tract of the Bhábar ends, a series of springs burst from the surface, and these, increasing and uniting in their progress, form the numerous streams that intersect the Tarai. The Deoha is the great river of the Tarai proper, and is navigable at Pilibhit. Elephants, tigers, bears, leopards, hyænas, and other wild animals are found in the district. The climate is normally bad, but improvement is gradually following the spread of sanitary measures.

According to the census of 1881 the population was 206,993 (113,315 males and 93,678 females). Hindus numbered 131,966 and Mohammedans 74,982. The only town with a population exceeding 10,000 is Kásipur, with 14,667 inhabitants. The whole tendency of the population is to agricultural and not to urban life. The total area under crop in 1884–85 was 254,288 acres, of which rice occupied 92,186 acres, wheat 54,627, and other food grains 80,304 acres. There are no manufactures worthy of note, and the chief trade is the export of grain. The gross revenue in 1884–85 amounted to £42,048 [$204,353.28], the land yielding £35,507 [$172,564.02]. The Tarai came under British rule at the time (1802) when Rohilkhand was ceded to the East India Company. The Government is said to have looked with indifference on this uninviting tract, but since 1831, when the revenue settlements were revised, this reproach has been less deserved. With an improved system of embankments and irrigation in 1851, the formation of the Tarai into a separate district in 1861, and its complete subjection to Kumáun in 1870, the moral and material history of this tract has greatly improved.

TARANTO. See TARENTUM.

TARANTULA. The tarantula (*Lycosa tarantula*) belongs to the mining section of the family *Lycosidæ* or Wolf Spiders. Its cephalothorax is dorsally of a brownish gray color, whilst the abdomen is more distinctly brown, and marked with either two or three pairs of triangular black spots above the apex of the triangles pointing backwards. One of the most striking specific characteristics of this spider is a large circular black spot which covers the anterior ventral half of the abdomen, the remainder of this surface presenting an ochreous hue. The largest species does not exceed ¾ inch in length. The eight eyes are arranged in three transverse rows, the anterior containing four small eyes, while behind this two pairs of larger eyes are arranged in two rows, the eyes of the hindermost row having between them a wider interval than the first pair.

The tarantula is widely distributed in southern Europe, round the shores of the Mediterranean. It occurs throughout Spain and is found in southern France, and extends into Asia. In Italy it is said to be especially common in Apulia, round the town of Taranto, from which place the name of this spider is usually derived. A species has also been described from northern Africa. It is usually to be found in dry pieces of waste land exposed to the sun. It lives in an underground passage, which it digs for itself and lines with its web. These passages are round in section, and sometimes an inch in diameter, and may extend to a depth of a foot or more below the surface. The tube first descends vertically for some inches, then bends at an obtuse angle, becoming vertical again near its closed end. The tarantula takes up its position at the first bend, where it can command the entrance, on the lookout for prey. In some cases the tube is prolonged above the surface of the earth by the formation of a small funnel, built up of fragments of wood and earth, and lined like the walls of the tunnel by the web. The females show considerable maternal care for their offspring, and sometimes sit upon their egg sacs; and the species, although somewhat fierce and combative amongst themselves, are capable of being tamed.

Tarantism. The tarantula has given its name to one of those dancing manias which overspread Europe during the Middle Ages. The bite of the spider threw the sufferer into a depressed state of melancholy, accompanied by various nervous disorders. The condition was accompanied by an increased sensibility to the power of music. The excitement of the nervous system amounted in some cases almost to insanity. The symptoms of the patient seem to have varied a good deal with the character of the individual attacked: the most common were a lividity of the body, icy coldness, great depression, nausea, sexual excitement, and loss of sight and hearing. The only means of arousing the sufferer from the lethargy into which he sank was music. Under the influence of this he awoke as it were, and commenced moving rhythmically, then began to dance, and continued increasing the rapidity of the motion until he fell exhausted to the ground. By this means it was considered that the poison of the tarantula was distributed through the system and worked out through the skin. If the music ceased whilst the patient was dancing, he at once sank back into the state of lethargy from which he had been aroused, but when thoroughly exhausted he generally awoke relieved and cured at least for a time. This dancing mania became contagious: one person caught it from another quite independently of the bite of the tarantula, and in this way whole districts became affected. One of the most peculiar characteristics was the attraction that bright pieces of metal, or brilliant pieces of color, exercised over the imagination of the dancers. This was particularly marked in the later history of the disease. Each sufferer apparently admired one particular hue, the sight of which seemed to cause him the greatest rapture. Red was a very general favorite, though this color threw St. Vitus's dancers into a frenzy of rage; green, yellow, and other colors also had numerous admirers. Other colors, on the contrary, they detested, and attempted to destroy articles of the obnoxious shade.

In marked contrast to the effect produced by hydrophobia, tarantism appeared to evoke in its victims an intense longing for the sea, into which at times they would precipitate themselves; at all times they seemed to prefer the vicinity of water, sometimes carrying globes of this fluid whilst dancing.

In its origin tarantism appears to have been contemporaneous with the St. Vitus's dance of Germany. It first appeared towards the end of the 14th century in Apulia; thence it spread gradually throughout Italy, and reached its height during the 17th century, by which time the dancing manias of the North had already died out. It affected not only inhabitants of the country but foreigners visiting it; age appears to have had no saving influence; children and old people alike commenced dancing at the sound of the tarantella, but as a rule women were more susceptible than men. From the 17th century onwards it has gradually declined, and is now practically unknown, the only relic of it being the graceful dance of southern Italy called the tarantella. The bite of the tarantula is painful but not dangerous, and the real cause of the phenomena described above must be sought in the temporary epidemic prevalence of an hysterical condition.

The *Lycosa tarantula* is figured in *Ann. Sc. Nat.*, 2d ser., iii. Zoologie, 1835.

TARARE, on the Turdine, a manufacturing town of France, and the second most populous in the department of Rhône, is 25 miles northwest of Lyons. Within a circle drawn 25 or 30 miles from the town more than 60,000 workmen are employed, and the value of the textile fabrics produced exceeds £600,000 [$2,916,000] per annum. Tarlatans are made in Tarare on more than 3000 Jacquard looms. The manufacture of Swiss cotton yarns and crochet embroideries was introduced at the end of last century; in the beginning of the 19th, figured stuffs, openworks, and zephyrs were first produced. The manufacture of silk plush for hats and machine-made velvets, which was set up a few years ago, now employs 2900 workmen and 500 girls, the latter being engaged in silk throwing and winding. There are, besides, four or five dyeing and printing establishments, and silk looms working for the Lyons trade. An important commerce is carried on in corn, cattle, linen, hemp, thread, and leather. In 1886 the population was 11,848 (commune 12,980).

Till 1756, when Simonnet introduced the manufacture of muslins from Switzerland, Tarare lay unknown among the mountains. On the old castle to which the town owes its origin may be seen the arms of the family of Albon.

TARASCON, a town of France, in the department of Bouches-du-Rhône, is situated on the left bank of the Rhone, opposite Beaucaire, with which it is connected by a suspension and a railway bridge. It is on the Lyons and Marseilles Railway, 156 miles south of the former town. The church of St. Martha, built in 1187–97 on the ruins of a Roman temple, rebuilt in 1379–1449, has a Gothic spire, and many interesting pictures in the interior, which is of fairly pure Pointed architecture. Of the original building there remain a porch, and a side portal with capitols like those of St. Trophimus at Arles. The former leads to the crypt, where are the tombs of St. Martha and Louis II., king of Provence. The castle, picturesquely situated on a rock, was begun by Count Louis II. in the 14th century and finished by King René of Anjou in the 15th. It contains a turret stair and a chapel entrance, which are charming examples of 15th-century architecture, and fine wooden ceilings. It is now used as a prison. The civil court of the arrondissement of Arles is situated at Tarascon, which also possesses a commercial court, a hôtel de ville, and fine cavalry barracks. Hats, and the so-called Arles sausages, are made here. The population in 1886 was 6647 (commune 9314).

The town wakes up for the fair of Beaucaire and the fête of La Tarasque, the latter in celebration of St. Martha's deliverance of the town from a legendary monster of that name. King René presided in 1469, and grand exhibitions of costume and strange ceremonies ,take place during the two days of the festival. Tarascon was originally a settlement of the Massaliots, built on an island of the Rhone. The mediæval castle, where Pope Urban II. lived in 1096, was built on the ruins of a Roman castrum. The inhabitants of Tarascon preserved the municipal institutions granted them by the Romans, and of the absolute power claimed by the counts of Provence they only recognized the rights of sovereignty. Tarascon played a bloody part in the White Terror of 1815.

TARAXACUM is the name usually applied in medical practice to the common dandelion (*Taraxacum officinale*, Wiggers). The Dandelion (*q.v.*) is a plant of the northern hemisphere, extending to the Arctic regions, and is cultivated in India. The preparations chiefly employed are the fluid extract, the preserved juice of the root, or succus, and the solid extract. The dried and roasted root, mixed with ground coffee, is often sold under the name of dandelion coffee for use as a beverage. The root is most bitter from March to July, but the milky juice it contains is less abundant in the summer than in the autumn. For this reason, the extract and succus are usually prepared during the months of September and October. After a frost a change takes place in the root, which loses its bitterness to a large extent. In the dried state the root will not keep well, being quickly attacked by insects. Externally it is brown and wrinkled, internally white, with a yellow centre and concentric paler rings. It is

2 inches to a foot long, and about ¼ to ½ inch in diameter. The juice when first exuded is bitter and neutral, but on exposure to the air soon acquires an acid reaction and a brown tint, coagulating and depositing a complex substance, to which the name of "leontodonium" has been given. From this deposit a bitter principle, "taraxacin," and an acrid crystalline substance, "taraxacerin," soluble in alcohol, have been obtained, but to which of these the medicinal properties are due is not known. In autumn the root contains about 24 per cent. of inulin, but in summer barely 2 per cent. When the juice has fermented, mannite is found in it. Taraxacum is chiefly employed as a stimulant tonic in hepatic disorders. In some cases it acts as a cholagogue and mild aperient, and in others as a diuretic.

The roots of other Composite plants are sometimes gathered by careless collectors for dandelion, especially that of *Leontodon hispidus* (L.). The root of this plant is tough when fresh, and rarely exudes any milky juice. The flowers, moreover, have feathery pappus, while in the dandelion it is simple.

TARBES, a town of France, chef-lieu of the department of Hautes-Pyrénées, is situated on one of the most beautiful plains of France, on the left bank of the Adour, streams from which are conducted through all parts of the town. The lines of railway from Paris to Pierrefitte and from Toulouse to Bayonne cross here. Among the many gardens and open spaces for which Tarbes is distinguished is the Massey garden (35 acres), given to his native town by a Versailles official of that name, in which his statue faces the town museum, founded by the collector Achille Jubinal. The varied collections include Roman remains, and specimens of the fauna and flora of the Pyrenees. The architecture of the cathedral is heavy and unpleasing, but the cupola of the transept (14th century), the modern glass in the 12th century apse, and a rose window of the 13th century, in the north transept, are worthy of notice. The Carmelite church has an interesting steeple, and there are the ruins of a chapel and cloister, and Roman remains in the garden of the former episcopal palace, now occupied by the prefecture. The municipal buildings, with the public library (22,000 volumes), the lyceum, the court of justice, and the barracks (which are large and fine) may also be mentioned among the public buildings. The garrison and artillery establishments, the latter associated with an arsenal and large workshops, have considerable importance. Other industrial establishments are a foundry, machine manufactory, felt and woollen factories, and wool and flax spinning mills. Paper, lace, knitted goods, carriages, and leather are also made here, and marble from the Pyrenees is prepared for the market. There are important fairs and markets, particularly for horses, as Tarbes is a well-known centre for a special breed of light horses, its stud being the most important in the south of France. The population of the town was 24,882 in 1886.

Tarbes, a mere *vicus* in the time of Gregory of Tours, rose into importance after the destruction of the ancient Aquitanian town of Turba. The seat of the bishopric was transferred to it about the 9th century, when a castle was also built. Raymond I., towards the middle of the 10th century, rebuilt the town, fortified it, and made it the capital of the county of Bigorre. The English held the town from 1360 to 1406. In 1569 Tarbes was burnt by Montgomery, and the inhabitants were driven out. This happened a second time, but in August, 1570, the peace of St. Germain allowed the inhabitants to return to the grass-grown streets. Subsequently Tarbes was four times taken and re-taken, and a number of the inhabitants of Bigorre were forced to take refuge in Spain, but in 1594 the members of the League were finally expelled. The English, under Wellington, gained a victory over the French near Tarbes in 1814. Théophile Gautier was born here in 1811.

TARENTUM, or Taras, now Taranto, a famous Greek city of southern Italy, situated on the north coast of the bay of the same name, at the entrance of the only secure port on the gulf. This port, now called the *Mare Piccolo*, is a bay 16 miles in circuit, landlocked by a low rocky peninsula. The entrance is so narrow that it is crossed by a bridge of seven arches; it was already bridged in Strabo's time. The modern town, in the province of Lecce, which is the see of an archbishop and had in 1881 a population of 26,611, stands on the peninsula, which is now rather an island, the isthmus connecting it with the mainland having been cut through for defence by Ferdinand I. The ancient citadel occupied the same site, but the city in its best days was much larger, traces of the walls being visible about 2 miles from the gates of the modern town. The remains of antiquity are inconsiderable.

Tarentum was a Spartan colony founded about the close of the 8th century B.C. (Jerome gives the date 708) to relieve the parent state of a part of its population which did not possess, but claimed to enjoy, full civic rights. Legend represents these *Partheniæ* (so they are called) as Spartans with a stain on their birth, but the accounts are neither clear nor consistent, and the facts that underlie them have not been cleared up. The Greeks were not the first settlers on the peninsula; recent excavations have brought to light signs of a pre-Hellenic trading place, and the name of Taras may be older than the colony. To the Greeks Taras was a mythical hero, son of Neptune, and he is sometimes confounded with the œcist of the colony, Phalanthus. Situated in a fertile district, especially famous for olives and sheep, with an admirable harbor, great fisheries, and prosperous manufactures of wool, purple, and pottery, Tarentum grew in power and wealth and extended its domain inland. Even a great defeat by the natives in 473 B.C., when more Greeks fell than in any battle known to Herodotus, did not break its prosperity, though it led to a change of government from aristocracy to democracy. A feud with the Thurians for the district of the Siris was settled in 432 by the joint foundation of Heraclea, which, however, was regarded as a Tarentine colony. In the 4th century Tarentum was the first city of Great Greece, and its wealth and artistic culture at this time are amply attested by its rich and splendid coins; the gold pieces in particular (mainly later than 360) are perhaps the most beautiful ever struck by Greeks (see Numismatics, vol. xvii. p. 653). In the second half of the century Tarentum was in constant war with the Lucanians, and did not hold its ground without the aid of Spartan and Epirote *condottieri*. Then followed war with Rome (281), the expedition of Pyrrhus, and at length, in 272, the surrender of the city by its Epirote garrison (see the details in vol. xx. p. 736 *sq.*). Tarentum retained nominal liberty as an ally of Rome. In the Second Punic War it suffered severely, when it was taken by Hannibal (212), all but the citadel, and retaken and plundered by Fabius (209). After this it fell into great decay, but revived again after receiving a colony in 123 B.C. It remained a considerable seaport, and its purple, second only to that of Tyre, was still valued, but in Strabo's time it had shrunk nearly to the limits of the present town. After the fall of the Western empire it was held from time to time by Goths, Lombards, and Saracens, but was not finally wrested from Byzantium till Robert Guiscard took it in 1063.

For special literature about Tarentum, see Busolt, *Griech. Gesch.*, i. 206 *sq.*

TARES, or Vetches. See Agriculture, vol. i. p. 334.

TARGUM (תַּרְגּוּם) in its concrete sense signifies the paraphrastic translation of the Hebrew Scriptures, or parts thereof, into the Aramaic tongue. It has, however, three other meanings: (1) a translation of any language into another;[1] (2) an interpretation in any language;[2] and (3) the Aramaic portions of certain books of the Bible (notably Daniel and Ezra).[3]

The word is not itself found in the Bible; but the participle *methurgam* (מְתֻרְגָּם) occurs in Ezr. iv. 7. The noun *Targum*, a form similar to Talmud (*q.v.*), occurs for the first time in the *Mishnah*, both canonical[4] and non-canonical,[1]—the latter being apparently the older source.

---

[1] Hence תרגום אשנזי' (German translation), etc.

[2] When the word is used in either of these two senses the language into which the translation is made, or in which an interpretation is given, must be specified, or otherwise indicated, *e.g.*, תרגום יוני' (Greek translation), תרגום השבע'ים (Septuagint), תרגם עקילס (Aquila translated), except when it is Aramaic, in which case the language may be named (as in Ezra iv. 7) or not (*Tosephto, Shabbath*, xiii. [xiv.] 2).

[3] Compare *Mishnah, Yadayim*, iv. 5.

[4] See last note.

Origin.—Although none of the Targums now in our hands are as old as the SEPTUAGINT (*q.v.*), the public use of Targums on Sabbaths, festivals, etc., is very ancient, and indeed their language was for several hundreds of years the sole one understood by the majority of the Jews in Palestine and Babylonia. How the Hebrew people of Judæa came so entirely to unlearn their own Hebrew tongue as to stand in need of an Aramaic translation of their Scriptures need not be dwelt on here (see vol. xi. p. 535 and vol. xxi. p. 679–680). But an important contrast between the Aramaic and Greek versions deserves particular notice. The use of the Septuagint by the Greek-speaking Jews of Alexandria, Asia-Minor, and elsewhere caused those who adopted it to forget entirely their own Hebrew tongue. The Aramaic version (Targum), however, springing from a religious necessity, was the cause of revival of the knowledge of Hebrew, which had been nigh forgotten. It is therefore easy to understand why the Jews in general have shown comparatively little attachment to the Septuagint, whilst they ever ardently revered the Aramaic version, even after the institution of publicly reciting it had ceased.[2] To this day pious Jews privately prepare themselves every Friday for the lessons of the coming Sabbath by reading the weekly portion twice in the sacred text and once in the Targum (שנים מקרא ואחד תרגום).

Former Use of the Targum in Public.—The following rules had to be observed in the reading of the Scriptures at the synagogal service:

I. As regards the Law (Pentateuch). (1) The private person called to the Law (which chiefly contains halakhic[3] matter) read one verse of it, which the official methurgeman or turgeman (translator) immediately paraphrased; (2) whilst the reader of the law was not allowed to take his eye off the written scroll, the methurgeman was forbidden, not merely to read out of a written Targum, but even to look into the sacred text;[4] (3) each of these had to wait till the other had quite finished the reading and translation respectively; (4) one was not allowed to raise his voice in a louder key than the other; (5) a certain number of passages, although allowed to be read, were not allowed to be translated; these were: (*a*) such as might reflect unfavorably on a father of a tribe, or on an eminent teacher (T. B., *Megill.*, 25*b*, *Tosaph.*, catchword מעשה); (*b*) such as might encourage the ignorant to think that there was some truth in idolatry; (*c*) such as might offend decency (*Mishnah*, *Megillah*, iv. 10; *Tosephto*, *ibid.*, 35, 37; T. Yer., *ibid.*, iv. 10; and T. B., *ibid.*, leaf 25*b*); (*d*) such as were fixed by the Lord Himself to be read in Hebrew only (as the sacerdotal benediction, Num. vi. 24–26);[5] (6) the translator was neither allowed to give a literal translation nor to add anything that had no foundation in the Divine word; he had to give the spirit of the letter.[6]

II. As regards the Prophets. (1) The person called to read the Prophets (which chiefly contain agadic matter[7]) might read three verses, of which the translator, who might be the reader himself,[8] sought to render the meaning to the best of his ability; (2) the translator was allowed both to read out of a Targum volume and to look also into the book containing the prophetic texts; (3) if reader and translator were two different persons they observed the third rule given above for the case of reading the Law; (4) here also certain passages were not allowed to be translated: (*a*) such as reflected on great men of the Israelite nation; (*b*) such as offend decency; (5) any one sufficiently intelligent might read, and of course paraphrase, the portion from the Prophets.

III. As regards the Hagiographa. The widest range of liberty must have been granted both to reciters and translators, as very scanty mention of any particular provision concerning it is to be found in the Talmuds. The Psalms and the book of Esther are classed together in so far as they may be read and paraphrased even by ten persons (T. B., *Meg.*, 21*b*). For Job and Lamentations, see below.

Duration of this Practice.—The practice of publicly reciting the Targum continued somewhat later than the last of the geonim. Within the last 400 years of that period, however, the power of this ancient institution began to fluctuate, gradually declined, and finally almost—but not entirely[9]—died out. The causes of this were two-fold. One was, that after the Mohammedan conquests Arabic supplanted Aramaic as the vernacular, and the Targums thus became unintelligible to the mass (see *Seder Rab ʿAmram*, i., Warsaw, 1863, leaf 29*a*), even as was already the case in the Western world. A second and more important cause, however, was the spread of Karaism, whose criticism of the Rabbinic contents of the Targums provoked the Rabbanites to pay more attention to the etymology and grammar of the Hebrew text of the Bible. Thus the Targums, both in their periods of vigor and decay, exercised, directly and indirectly, a salutary influence. In each case the knowledge of Hebrew was promoted; and it advanced so much, that by 1000 A.D. the Jews of Iraḳ, like those of the rest of the world then, and as in our own days, certainly knew the pure Hebrew better than the Aramaic idiom. The same was the case in other Arabic-speaking parts, as Spain, Africa, etc.,—Yemen then and still forming a solitary exception.[10]

Authorship and Age of the Various Targums.—The Targums on the various books of the Bible are not merely by various authors, but also of various ages. They have only one thing in common,—all of them rest on oral traditions, which are hundreds of years older than the earliest form of the written Targums now in our hands. We enumerate them according to Biblical order, although that is not necessarily the chronological order in which they were either composed or committed to writing.

---

[1] *Siphere* (see vol. xvi. p. 581) on Deuteronomy (Pericope *Shophetim*), *Pisko* 161.

[2] "Let not the Aramaic be lightly esteemed by thee," says the Jerusalem Talmud, "seeing that the Holy One (blessed be He!) has given honor to it in the Pentateuch (Gen. xxxi. 47), in the Prophets (Jer. x. 11), and in the Hagiographa (Dan. ii. 4)," (*Sotah* vii. 2). Instead of "Arammi" (Aramaic) the *Midrash Rabbah* on Genesis reads "Parsi" (Persian); the reading here is "Sursi" (Syriac).

[3] See MISHNAH, vol. xvi. p. 526–528.

[4] This was done to prevent its being thought that the Targum (the exponent of the oral Law) was to be found in writing in the Pentateuch (the exponent of the written Law).

[5] The Babylonian Talmud (*Megillah*, 25*b*) says that the priestly benediction was not to be recited in Aramaic on account of the phrase "the LORD shall lift up His countenance upon thee," which would appear as if the Lord had been a respecter of persons. In Talmudic times they had apparently, in Babylonia, lost the real reason of the Mishnic prohibition, which is that this benediction is doubly, yea, trebly Divine, being framed in its every word by God Himself, and can thus only be recited in those very words (כה, thus: Num. vi. 23). See *Mishnah*, *Sotah*, vii. 2; T. Yerushalmi, *ibid.*, and *Megillah*, iv. 11, and, finally, *Bemidbar Rabbah*, cap. xi. *in medio*.

[6] See *Tosephto*, *Megillah*, iv. *in fine*.

[7] See MIDRASH, vol. xvi. p. 297.

[8] Thus Jesus (Luke iv. 16–27) no doubt read the *Haphtarah* (prophetic portion) himself, and paraphrased it himself. From this custom of reading and paraphrasing by one and the same person the sermon (דרשה) sprang. The passage in question (Isa. lxi. 1, etc.) was read on the Sabbath before the New Year (day of memorial).

[9] Long after the institution of publicly reciting the Targum on the Law had generally declined, it was yet retained in Germany and Italy on certain days of the three high festivals, viz., (*a*) the seventh day of Passover, (*b*) the first day of Pentecost, and (*c*) the last day attached to the festival of Tabernacles (*i.e.*, שמחת תורה). The passages so recited were—(*a*) parts of the lesson for the day—the song of Moses and the children of Israel, with the introduction; (*b*) the Decalogue in Exodus; (*c*) the last portion of Deuteronomy. In the first case the paraphrase was from the three Targums mixed, in the second from the Targum Yonathan with deviations, in the last from the Targum Onkelos. (These pieces are interspersed with sundry bits of poetry; see Camb. MS. Add. 374, leaves 169*a*–171*b*, 199*a*–203*a*, 423*b*–427*b*.) Towards the end of the 14th century, as regards Passover and Pentecost, the custom fell into desuetude, but down to our own days some of the congregations of Italy continue the usage of reciting the Targum Onkelos in connection with the narration of the death of Moses. This custom, however, is now rapidly dying out. As regards the recitation of the Targum on the Prophets, a small remnant of the congregations following the rite of Rome (*i.e.*, the so-called *Italiani*) continue it to this day on the festival of Passover. For the use of the Targum on Pentecost, see *Responsa*, by R. Meir of Rothenburg (ROSH, *q.v.* footnote 3), No. 59.

[10] In Yemen the Targum is publicly recited to this day, and, strange to say, by boys of nine years of age or so in turn. See J. Saphir, *Eben Sappir*, i. (Lyck, 1866, 8vo.), leaves 53*b*, 61*a*. Saphir once told the present writer that a youth, eighteen years of age (*ut supra*, 61*b*), who carried his travelling-bag and served as his guide over the mountains, Saïd, *i.e.*, Seʿadyah, by name and a shoemaker by trade, could translate to him in Aramaic from memory any passage Saphir recited in Hebrew.

I. *The Pentateuch.*— *a*) There is a complete Targum known as *Onḳelos* (אונקלוס, אונקלס, אנקלוס, אונכילוס). The person and even the name of Onḳelos have been for the last three hundred years a *crux criticorum.*

According to the Babylonian Talmud, *Megil.*, 3*a*, "Onḳelos (son of Calonicus, *Gitt.*, 56*b*, or of Calonymus, '*Ab. Zar.*, 11*a*), the proselyte, composed the Targum on the Pentateuch (אֲמָרוֹ) out of the mouth of R. Eli'ezer and R. Yehoshua'," who taught in the 1st and 2d centuries. In the Jerusalem Talmud, *Meg.*, i. 9, the same thing is related on the same authorities, and almost in the same words, of the proselyte Aquila (Akylas) of Pontus, whose Greek version of the Bible was much used by Greek-speaking Jews down to the time of Justinian (*Nov.*, cxlvi. cap. 1).[1] There are other parallels between what *Tosephto* and the Babylonian Talmud tell of Onḳelos and what the Jerusalem Talmud and the Midrash tell of Aquila. Both throw their idolatrous inheritance into the Dead Sea (*Tos.*, *Demai*, vi. 12; T. Y., *Demai*, vi. 10), and both have connections with Roman emperors, Onḳelos being sister's son of Titus (*Gittin*, 56*b*), and Aquila of Hadrian (*Midr. Tanḥ.*, *Mishpatim;* see, also, for Onḳelos, '*Ab. Z.*, 11*a*, and for Aquila's connection with Hadrian, T. Y., *Ḥag.*, ii. 1; *Shem. Rab.*, xxx.; Epiphanius, *De Mens. et Pond.*, xiv. *sq*.). From these facts some (see N. Adler, *Nethinah lagger*, in the Vilna Pent., 1874, Introd.) still argue that Onḳelos is but another name for Aquila, and that the Greek translator also wrote our Targum. This view was long ago refuted by R. 'Azaryah de' Rossi,[2] and is quite untenable. It is incredible that Aquila or any other Greek could have had the mastery of Aramaic and of traditional lore as well as of Hebrew which the Targum displays; and the phrase of T. Y., *Megil.*, i. 9, "an untutored person picked out for them Aramaic from the Greek," is quite inapplicable to Onḳelos, and ought to be taken as referring to the Peshito Syriac, which is admittedly dependent on the LXX. In a Jewish writing "for them"—set absolutely—means "for the Christians." The view now accepted by most critics is that the word Onḳelos is a Babylonian corruption of Akylas, but that the name "Targum Onḳelos" originally meant no more than "Targum in the style of Aquila," *i.e.*, bearing to the freer Palestinian Targums a similar relation to that of Aquila's version to the Septuagint.[3] On this view there never was a real person called Onḳelos. But how Akylas (עקילס; in *Ber. Rab.*, i. middle, אקילוס or אקילין, *i.e.*, אקילץ) could be corrupted into Onḳelos has not been satisfactorily explained; and, besides the traditions about Onḳelos which resemble what is known about Aquila, there are others, and these older than either *Gemara*, which have no such resemblance, and assign to him an earlier date, associating him with R. Gamliel the elder, the teacher of St. Paul (*Tosephto, Shab.*, vii. [viii.] 18; *Ḥag.*, iii. 2, 3; *Kel. Bab. Bath.*, ii. 4; *Miḳv.*, vi. 3; Talmud B., '*Ab. Zar.*, 11*a; Mas. Semaḥ.*, viii. init.). The *Zohar* (iii. leaf 73*a* of the small ed.) ascribes his being circumcised to Hillel (R. Gamliel's grandfather) and Shammai. These notices, it is true, do not speak of Onḳelos as a targumist; and, indeed, the Targum being a representative piece of the oral law was certainly not written down, private notes (*megilloth setharim*) excepted, before the *Mishnah, Tosephto*, etc., *i.e.*, till about the end of the 6th or the beginning of the 7th century. But in the opinion of the present writer this need not prevent us from recognizing Onḳelos as a corrector and compiler of oral Targum in the 1st century. As regards the name, it may be suggested that Onḳelos is a deliberate perversion of Evangelus, a Greek proper name which exactly translates the Jewish (and especially Babylonian-Jewish) name Mebasser. As the Christian writings are called *Aven* (iniquity, idolatry), and as the pre-Mishnic teacher R. Meir calls the gospel (*evangelion*) *ongillayon* (iniquity of the roll; T. B., *Shab.*, leaf 116, Amst. ed. of 1645), or, by inversion, *gilyon-aven* (roll of iniquity), the name Evangelus, which suggested associations with the gospel, might be perverted into Onḳelos *quasi* On-ḳeles (iniquity of disgrace). And, while a Babylonian Jew coming to Palestine might find it convenient to translate his Hebrew name into Evangelus, this good Greek name was enough to suggest in after times that he was of heathen origin and so to facilitate the confusion with Aquila. The idiom of the Targum Onḳelos, which is held to be Palestinian with some Babylonian features, points to Babylonia as the country of its final redactor, if to Palestine as its source. It must be remembered that Hillel and other great fountains of Palestinian learning were of Babylonian origin.[4]

(*β*) Certain Targumic fragments on the Pentateuch go under the name of *Targum Yerushalmi*, or, rather, *Palestinian Targum.* These are the remains of a much larger *Jerusalem Targum*, once current in Palestine. But, the Palestinian rabbis not having approved of it, perhaps because it accorded in various of its interpretations and phrases with interpretations and phrases to be found in the Gospels,[5] it gradually lost its authority and the greater portion of its original matter, and is now in our hands what it is. It certainly never was part of the *T. Onḳelos*, nor was the *T. Onḳelos* part of it, though the two are closely related. As regards its age, several of the pieces formerly found in it (now in *T. Yonathan*) were in the 2d and 3d centuries distinctly quoted[6] with disapprobation. But like *Onḳelos* it cannot have been written down before the *Mishnah* and other parts of the oral Law.[7]

(*γ*) The *Targum Yonathan*, or *T. of Jonathan, on the Pentateuch* is also Palestinian. This Targum was no doubt undertaken, as Dr. Bacher has shown (*Z.D.M.G.*, xxviii. p. 69), to combine the finest parts of what early *T. Onḳelos* and *T. Yerushalmi* contained. This attempt could not have been made without both these Targums lying in writing before the compiler of the third Targum. The *Targum Yonathan* on the Pentateuch is a product, at the earliest, of the 7th century, to which conclusion internal evidence also points.[8] The author is, of course, not the Yonathan b. 'Uzziel, principal of the eighty disciples of Hillel (T. B.,

---

[1] For the connection of Aquila with R. Eli'ezer and R. Yehoshua', see also *Beresh. Rab.*, lxx.; *Bemidb. Rab.*, viii. end; *Kohel. Rab.*, vii. 8.

[2] *I.e.*, "min Haadummim." The Adummim are supposed to be one of the four noble families carried to Rome by Titus.

[3] The Jerusalem Talmud repeatedly cites Aquila's renderings and never names Onḳelos. But it does show acquaintance with renderings found in Onḳelos (*e.g.*, *Megil.*, iv. 11; *cf.* Onḳ. on Exod. xxxii. 35). In the *Midrash Rabbah*, besides many citations from Aquila, we find one of Onḳelos by name (in *Bem. R.*, ix. *in fine;* Onḳ. on Deut. xxxii. 24) and various allusions (without name) to renderings found in him. He is also cited by name in the Palestinian Pireḳe de-R. Eli'ezer, xxxviii.

[4] *Bibliography of the Targum* אונקלוס.—(A) There are very fine MSS. of this Targum at Parma, Oxford, Cambridge (Dd. 11, 26, Add. 446, 1053), the British Museum, Kissingen (Rabbin Bamberger), etc. (B) A Massoreth on our Targum by an anonymous author, who must have lived in or before the 12th century, has been published—(1) by Luzzatto (*Oṣar Neḥmad*, iv.); (2) by Adler (Vilna edition of the Pentateuch of 1874); and (3) by Berliner (with a German translation, etc., Leipsic, 1877, 8vo). (C) Leading editions: (1) Bologna, 1482, *editio princeps*, without vowel-points; (2) the Complutensian polyglott; (3) the Bomberg Rabbinic Bible of 1517; (4) Sabbioneta, 1557, 16mo (reprinted, not without mistakes, at Berlin, 1884, imp. 8vo); and (5) Vilna edition of the Pentateuch of 1874, the Targum being pointed according to a Bodleian MS. (Canon. Orient. 91). (D) Translations: (*a*) into Latin—(1) by Alphonsus Zamorensis (*Polygl.*, 1517, etc.); (2) by P. Fagius (Strasburg, 1546, folio); (*b*) into English by Etheridge (*Targums*, London, 1862–65, 8vo). (E) Commentaries, all in Hebrew: (1) *Pathshegen*, by an anonymous Provençal rabbi of the 12th century (see MAḤZOR), in the Vilna Pentateuch of 1874; (2) by R. Mordekhai b. Naphtali (Amsterdam, 1671–77, fol.); (3) *Leḥem Vesimlah* (double commentary) by R. Bensiyyon Berkowitz (Vilna, 1846–56); (4) by Dr. Nathan M. Adler (Vilna Pentateuch of 1874, *ut supra*). (F) Other literature (also for the other Targums): (*a*) in Hebrew—*Meor 'Enayim*, by R. 'Azaryah m. Haadummim (cheapest and best edition, Vilna, 1863; *Mine Targumo*, by R. Y. Berlin or Pick (Breslau, 1851, 4to); *Oheb Ger*, by S. D. Luzzatto (Vienna, 1830); '*Oteh Or*, by the before-named B. Berkowitz (Vilna, 1843); *Iggereth Biḳḳoreth*, by R. Z H. Ḥayyuth (Chajes), ed. Brüll, Presburg (1853, 8vo); Rapoport, '*Erekh Millin* (Prague, 1852, 4to); Löwy, *Biḳḳoreth Hattalmud*, i. (Vienna, 1863, 8vo); (*b*) in Latin—Morinus, *Exercitationes*, ii. viii. 6 (Paris, 1660); Winer, *De Onkeloso* (Leipsic, 1820, 4to); R. Anger, *De Onkelo* (Leipsic, 1845–46); (*c*) in German—Zunz, *Gottesd. Vorträge* (Berlin, 1832); Geiger, *Urschrift* (Breslau, 1857); Hamburger, *Real-Encyklopädie; Targum Onkelos*, by Dr. A. Berliner (Berlin, 1884, imp. 8vo). On this work, see Nöldeke, in Zarncke's *Centralbl.*, 1884, No. 39, and Lagarde in *Gött. Gel. Anzeig.*, November, 1886 (No. 22); (*d*) in English: E. Deutsch, in his *Literary Remains*—to be used with caution. (G) Lexicons to this and other Targums: (1) as for the Talmuds and Midrashim, so also for the Targum, R. Nathan b. Yehiel's '*Arukh* (see TALMUD, p. 37, note 7) stands first; (2) next to it is Elias Levita's *Methurgeman* (Isny, 1541, fol.); (3) Buxtorf's *Lexicon Chaldaicum, Talmudicum, et Rabbinicum* (cheap and new, though by no means best, edition, Leipsic, 1869–75); (4) Levy's *Chald. Wörterb.* (1866–68); (5) Jastrow's *Dictionary*, i., ii. (New York, 1886). (H) Grammars: (1) Juda Jeitteles's *Mebo Hallashon* (Prague, 1813, 4to); (2) Blücher's *Marpe Leshon Arammi* (Vienna, 1838); (3) Fürst's *Lehrgeb. d. Aram. Idiome* (Leipsic, 1855); (4) Lerner's *Diḳduḳ Lashon Arammith* (Warsaw, 1875); all in 8vo.

[5] See T. Yer., *Berakhoth*, v. 3, and compare with it Luke vi. 36. Compare Berliner, *ut supra*, pp. 85, 86.

[6] Compare last note.

[7] *Bibliography of the Targum Yerushalmi on the Pentateuch.*—(A) There is a MS. of this Targum preserved in the Vatican library (ccccxl.). (B) The first edition of this Targum is in the so-called Christian Rabbinic Bible of 1517. It is to be found also in most polyglott and Rabbinic Bibles, including the Polish editions (Warsaw, etc.). (C) Translations: (*a*) Latin—(1) by Taylerus (London, 1649, 4to); (2) by Chevalier (in the *Polyglott*, London, 1653–57). (*b*) In English by Etheridge (*Targums*, London, 1862–65, 8vo). (D) There are two commentaries on this Targum in Hebrew: (1) by R. David b. Ya'aḳob (Prague, 1609, 4to); (2) by R. Mordekhai b. Naphtali (Amsterdam, 1671–77, fol.).

[8] See our Targum on Gen. xxi. 21, where Mohammed's first wife (Khadīdja) and their youngest daughter (Fātima) are mentioned by name.

Sukkah, 28*a*), who, according to T. Bab., *Megill.*, 3*a*, composed a Targum on the Prophets from the traditions of Haggai, Zechariah, and Malachi.[1]

II. *Targum Yonathan on the Prophets.*—It has been known from early quotations, as from RASHI (*q.v.*) and others, but notably from ḲIMḤI (*q.v.*), that, in addition to the complete extant Targum on the Prophets, there existed other Targums or fragments of them. These are now known from the marginal additions to the Reuchlinian Codex of the Targum on the Prophets published by Lagarde (Leipsic, 1872), and have been discussed by Bacher (*ut sup.*). As regards the complete Targum on the Prophets, no mistake can be greater than to believe that Rab Yoseph, a teacher of the 3d and 4th centuries, and head of the academy of Pumbaditha (see RABBAH), was the author of this Targum in whole or in part. This mistake has its origin in the repeated phrase of the Babylonian Talmud, כדמתרגם רב יוסף ("as Rab Yoseph targumizes"); but then a similar phrase exists with regard to Rab Shesheth, כדמתרגם רב ששת ("as Rab Shesheth[2] targumizes"). And in like manner the expression כדמתרגמינן ("as we targumize") is of frequent occurrence. In this last instance the words mean "as we are in the habit of translating certain passages in Holy Writ according to a Targum we have received." As applied to Rab Yoseph and Rab Shesheth the phrase may certainly mean more and yet not imply that these teachers were in any way authors of the Targum on the Law, the Prophets, or Hagiographa. Rab Yoseph and Rab Shesheth were both blind, and as such were not allowed to quote *in extenso* the written word of the Law, which it was forbidden to recite orally. They therefore committed to memory the oral Targum, and so were, of course, appealed to as Targumic authorities, etc.[3] That Rab Yoseph was not the author of the Targum on the Prophets will be clearly seen from the following Talmudic passage (B., *Megillah*, 3*a*; *Mo'ed Katan*, 28*b*): "Were it not for the Targum of that verse [Zechar. xii. 11] I should not know the meaning of the prophet." This verse is from the last but one of all the Prophets;[4] and we see that Rab Yoseph must have had the Targum on the Prophets before him. In the opinion of the present writer this Targum was composed by Yonathan; and, not being on books of the Law, there was no reason why it should not have been there and then written down.[5] Although the traditions it embodies came originally from Babylonia and returned to Babylonia, its language has yet a more marked coloring of the Palestinian idiom than that of Onkelos, because it was not studied so much and therefore not so much modified and interpolated. Some of the Agadoth occurring in this Targum are ascribed in the Talmud and Midrash to later men, but this is no conclusive argument against an early date. It can be shown that many laws and sayings supposed to be of the 2d, 3d, and 4th centuries of the Christian era are actually of pre-Christian times, and, indeed, certain explanations, figures of speech, etc., had been, so to say, floating in the air for centuries. Certain passages in the Septuagint contain Agadoth which reappear, seemingly for the first time, in the Talmudic literature. The Prophets themselves knew Agadoth which only reappear in what are believed to be late Midrashim (comp., *e g.*, Isaiah xxix. 22 with T. B., *Synh.*, 19*b*; Isa. xxx. 26 with Targum on Judges v. 31, *Ber. Rab.*, xii.; Ezek. xxii. 24, etc., with *Ber. Rab.*, xxxiii.).[6]

III. *Targum on the Hagiographa.*—No author's name is attached to this Targum in whole or in part. The Psalms must have had one[7] or two[8] Targums; the book of Proverbs at least two;[9] the book of Job at least three.[10] There must have been two Targums on Canticles,[11] Ruth,[12] Ecclesiastes,[13] and Esther,[14] and probably three on Lamentations,[15] the earliest of which was, no doubt, simultaneously coming into existence with the earliest on the book of Job. For Ezra-Nehemiah no Targum exists. Daniel only in part wanted a Targum, and it is supposed to have had one;[16] and the books (or rather the book) of Chronicles have a by no means late one,[17] although it is not by Rab Yoseph, of the 4th century.[18]

State of Text.—The Targum text is, taken as a whole, in a very corrupt state. The causes of this corruption are many, but chiefly the following: (1) mistakes ordinarily made by scribes through carelessness, or ignorance, or both; (2) the Targums had passed from century to century and from country to country without having been written down; (3) when written down they were probably not provided with vowel-points at once; (4) when provided with vowel-points most of them were first provided with Babylonian (or Assyrian), which afterwards were changed into Palestinian ones; this change was a fertile source of fresh mistakes; (5) the loss of the general knowledge of the Targumic idiom contingent on the decline and final fall of the institution of publicly reciting the Targum was an additional source from which mistakes arose; (6) conjectural emendations contributed their quota to the corruption of the text; (7) Buxtorf's emendations founded on the diction of the Biblical Targum (as suggested in the *Methurgeman*) are a gross mistake, inasmuch as they lack the criticism of history; (8) printers' mistakes, increasing in every new edition, have all but ruined the text. The remedies for this corruption are: (1) good Targum MSS. in private hands and public libraries, notably in Italy, Germany, and England; (2) Targum MSS., according to the Babylonico-Assyrian system of punctuation, chiefly preserved in South Arabia, Russia, and England; (3) some early and comparatively good printed editions; (4) the *Massoreth* of the Targum.

---

[1] *Bibliography.*—(A) There certainly exists, somewhere in Italy, a MS. of this Targum, although the owner is at present unknown. (B) This Targum appeared for the first time in the Pentateuch edition of Venice (1590–91, 8vo). (C) Translations: (*a*) Latin by Chevalier (London, 1653–57); (*b*) in English by Etheridge (*op. cit.*). (D) Commentaries: (1) by R. David b. Ya'akob (Prague, 1609, 4to); (2) by R. Mordekhai b. Naphtali (Amst., 1671–77, fol.); (3) by an anonymous author in the Warsaw edition.

[2] In the editions before us (T. B., *Sotah*, 48*b*) *Yoseph* stands on the margin instead of *Shesheth*; but in the edition before R. 'Azaryah m. Haadummim the reading was absolutely *Shesheth*; see *Meor 'Enayim*, cap. xlv.

[3] See *Tosaphoth* on *B. Ḳam.*, leaf 3*a*, catchword כדכתרגם.

[4] This is by no means an isolated phrase; in T. B., *Synhedrin*, 94*b*, a similar one occurs, referring to Isa. viii. 6.

[5] See, however, vol. xxi. p. 680.

[6] *Bibliography.*—(A) There are MSS. of the Targum on the Prophets in the Bodleian (Opp. Add., 4to, 75 and 76, Uri 4 and Kennicott 5). (B) The earliest edition is in the Rabbinic Bible of 1517. (C) Translations: (*a*) in Latin—(1) by Alphonsus Zamorensis (revised by Arias Montanus and afterwards by Clericus); (2) Jeremiah, by Ghislerus, 1623; (3) Minor Prophets, by Mercerus, 1559, Tremellius, 1567, and Figueiro, 1615; (4) Hosea, Joel, and Amos, by Quinquarboreus, 1556; (5) Obadiah, by Bedwell, 1601, and Leusden, 1656; (*b*) in English—Isaiah, by Pauli (London, 1871, 8vo). (D) Besides the general literature mentioned under "*Onkelos*" (*in fine*), we must mention Frankel, *Zum Targum der Propheten* (Breslau, 1872, 4to), which must be used with caution.

[7] See T. B., *Megillah*, 21*a*, and also Rashi on T. B., *Ta'anith*, leaf 18*a*. Zunz is greatly mistaken when he says (*Gott. Vortr.*, p. 64) that the Targums on Psalms, Job, and Proverbs have one and the same linguistic character. The Targum on Proverbs is almost pure Syriac.

[8] See the Targum itself on Psalm lxxvi. 11.

[9] There, no doubt, existed another Targum on this book, older than that now in our hands; see *Ber. Rab.*, xciii.

[10] See the extant Targum on Job xxiv. 19, and comp. note 19 *infra*.

[11] See R. Nathan b. Yeḥiel's *'Arukh*, s.v. פלטיא. A "Yerushalmi Targum" presupposes at least one other.

[12] The Targum on the Five Megilloth has all one character, and is therefore wholly Yerushalmi.

[13] The Targum itself repeatedly quotes another Targum.

[14] See Rashi on T. B., *Megillah*, leaf 13*b*, catchword זכה. We have still two Targums on Esther. It ought to be mentioned here that in the post-Talmudic *Massekheth Sopherim*, xiii. 6, an Aramaic translation of Esther iii. 1 is given, with the introductory words: רב יוסף תרגם ("Rab Yoseph targumized"). This somewhat lengthy translation is found (the quotation from the Targum on Proverbs excepted) almost verbatim in the *Targum Sheni in loc.*

[15] The book of Lamentations, and consequently a Targum thereon, was no doubt used along with the book of Job and the Targum thereon, by mourners. See Schiller-Szinessy, *Catalogue*, i, p. 27.

[16] See Munk, "Notice sur Saadia" (Cahen, *La Bible: Isaie*, Paris, 1838), p. 159. His ingenious remarks are scarcely borne out by fact.

[17] From a late name occurring in a book no conclusions must be drawn, as isolated words may be a mere interpolation. The internal character of a work must decide the age in which it was composed.

[18] *Bibliography.*—(A) There are MSS. of the Targum—(1) on the Psalms, in Parma (De-Rossi, 31, 32, 732) and Paris (110); (2) on Proverbs, in Parma (31, 32) and Paris (as before); (3) on Job, in Parma (31, 32) and Paris (as before); (4) on the Five Megilloth, in the Court Library of Vienna (xxix.), Parma (31, 32), the Bodleian (Uri 1, 44), Cambridge (Add., 436); and (5) on Chronicles in the Vatican (Urb. i.), the Erfurt ministerial library, Cambridge (E 5, 9), and the Bodleian (Uri 35, 36). (B) The earliest editions of the Targum on the Hagiographa (except on Daniel, Ezra-Nehemiah, and Chronicles) are the Rabbinic Bibles, and on Chronicles those of 1680–83 by Beck and 1715 by Wilkins. (C) Translations:—(*a*) in Hebrew—the *Targum Sheni*—(1) *Leshon Zahab* (Const., 1732), and (2) *Pathshegen hakkethab* (Amst., 1770, repr. at Czernowitz, 1838),—all 8vo; (*b*) in Latin—(1) on the Psalms, by Aug Justinianus, and again by Arias Montanus; (2) on Proverbs, by Alphonsus Zamorensis; (3) on Job, by the same; (4) on Canticles, by the same, and again by Schreckenfuchs (Basel, 1553, 8vo); (5) on Ruth, by Arias Montanus, Quinquarboreus (Paris, 1556, 4to), Mercerus (Paris, 1564–65, revised 1657); (6) on Lamentations, by Alph. Zam., by Quinquarboreus (Paris, 1549, 4to), by Ghislerus (Leyd., 1623, fol.), and again by Taylerus (Lond. 1651, 4to); on Ecclesiastes, by Ar. Mont., by Schreckenfuchs (Basel, 1555, 8vo), and again by Costus (Leyden, 1554, 4to); (7) on Esther, by Ar. Mont. (1572, folio); (8) Chronicles by Beck from the Erfurt MS. (imperfect, Augsb., 1680–83), and by Wilkins from the Cambridge MS. (Amst. 1715); (*c*) in German—(1) on the Five Megilloth, by R. Ya'akob b. Shemuel (Breisgau, 1584, 4to); (2) on the *Targum Sheni*, by David Ottensosser (Sulzbach, 1820, 8vo). (D) Commentaries: (*a*) in Hebrew—(1) on the Targum of the Five Megilloth, by R. Elyaḳim Rothenburg (Prague, 1618); (2) on Esther alone, by R. Shemuel Makshan (Prague, 1601, 4to); (3) on the same Targum, by R. David b. Yehudah Melammed (Cracow, 1644, 4to); on the *Targum Sheni*, by R. David b. Ya'aḳob (Prague, 1609, 4to); (*b*) in Spanish—on Canticles, by R. Mosheh Laniado (Venice, 1619, 4to).

Value of the Targums.—The idea so long entertained, even by the learned, that these old versions were valuable chiefly as guides to the original readings of the sacred text must be given up. All of them contain more or less, whether visible at first sight or not, certain paraphrastic elements, which give no absolute security for the exact reading of the pristine Hebrew text. But besides their importance as linguistic monuments they have the highest value as historical records—(1) of the exegesis which obtained at the time of their composition, and (2) of the then current manners, thoughts, and aspirations both of the Jews and of the surrounding nations.[1] (S. M. S.-S.)

TARIFA, a seaport of Spain, in the province of Cadiz, at the extreme south point of the Peninsula, 59 miles southeast from Cadiz and (by land) 21 miles west-southwest from Gibraltar. The town is nearly quadrangular, with narrow crooked streets, and is still surrounded by its old Moorish walls. On its east side, just within these, stands the alcazar. The rocky island in front of the town, connected with the mainland by a causeway, is strongly fortified, and in some sense commands the Strait of Gibraltar. It has a lighthouse, 135 feet high, which has a range of 30 miles. The population within the municipal limits was 12,234 in 1877. Anchovy and tunny fishing is carried on, and there is some coasting trade. The manufactures (leather and earthenware) are unimportant. The oranges of Tarifa are famed for their sweetness.

Tarifa is the *Julia Joza* of Strabo, between Gades and Belon, which, according to that writer, was colonized by Romans and the removed inhabitants of Zelis in Mauretania Tingitana. The *Julia Transducta* or *Traducta* of coins and of Ptolemy appears to be the same place. Its present name (Arabic *Jazírat Ṭaríf*) is derived from Ṭaríf, the forerunner of Ṭaríḳ (see vol. xvi. p. 596). After a long siege it was taken from the Moors in 1292 by Sancho IV. of Castile, who entrusted it to the keeping of Alonzo Perez de Guzman; the heroic defence by the latter, commemorated in the *Romancero*, earned for him the name of Guzman "el Bueno." It was in the defence of Tarifa that Alfonso XI. gained the battle of Salado, a short distance to the westward, in 1340. The place was successfully defended against the French by Gough in 1812.

TARN, a department of southern France, formed in 1790 of the three dioceses of Albi, Castres, and Lavaur, all belonging to the province of Languedoc, lies between 42° 23′ and 44° 12′ N. lat. and 1° 32′ and 2° 56′ E. long. It is bounded N. and E. by Aveyron, S.E. by Hérault, S. by Aude, S.W. and W. by Haute-Garonne, N.W. by Tarn-et-Garonne. The slope of the department is from east to west, and its general character is mountainous or hilly; its three principal ranges, the Mountains of Lacaune (peak of Montalet, 4154 feet), the Sidobre, and the Montagne Noire, belonging to the Cevennes, lie on the southeast. The stony and wind-blown slopes of the first-named are used for pasturage. The highest point of the range and of the department is the Pic de Montalet (4154 feet); several other summits are not much short of this. The granite-strewn plateaus of the Sidobre, from 1600 to 2000 feet high, separate the valley of the Agoût from that of the Thoré. The Montagne Noire derives its name from the forests on its northern slope, and some of its peaks are from 3000 to 3500 feet high. The limestone and sandstone foot-hills are clothed with vines and fruit trees, and are broken by deep alluvial valleys of extraordinary fertility. With the exception of a small portion of the Montagne Noire, which drains into the Aude, the whole department belongs to the basin of the Garonne,—indeed, if the rivulet Giron be excepted, to that of the Tarn, which flows in a westerly direction past Albi, Gaillac, Lisle, and Rabastens, receiving on the left the Agoût at St. Sulpice. Northern Tarn is drained by the Aveyron and its tributary the Viaur. The eastern portion of the department has the climate of Auvergne, the severest in France, but that of the plain is Girondin. At Albi the mean temperature is 55°, and the rainfall 29.5 inches. The population of the department in 1886 was 358,757.

Of the total area of 2217 square miles, or, 1,418,969 acres, there are 887,709 acres of arable land, 118,071 of meadows, 118,934 of vineyards, 186,594 under wood, and 52,408 of moorland. By last returns there were 11,360 horses, 3280 mules, 5430 asses, 20,550 bulls and oxen, 53,900 cows and heifers, 13,240 calves, 455,500 sheep (wool-clip in 1878 1209 tons), 87,700 pigs, 5350 goats, and 17,190 bee-hives. In 1878 37 tons 14 cwt. of silk cocoons were produced. Oxen and sheep are fattened; ewes' milk cheese like that of Roquefort is made; and geese and turkeys are reared. The crops in 1881 were: wheat, 3,429,112 bushels; meslin, 53,113; rye, 1,371,040; barley, 37,730; buckwheat, 8448; maize and millet, 1,566,873; oats, 538,422; potatoes, 2,554,860; dry vegetables, 374,715; chestnuts, 268,125; beetroot, 196,625; 782 tons of hemp; 476 of flax; 9,676,476 gallons of wine (only half the quantity of the previous year, owing to the phylloxera). Both common and good table wines are produced.

The mineral products include marble, porphyry, granite, lime, manganese, sulphate of baryta, alum, iron, lignite, and tourmaline. In 1881, 335,430 tons of coal were taken from seven pits, and other mines are about to be opened. There are iron, alkaline, thermal, and carbonate of lime springs. The chief centre for the manufacture of woollen stuffs (in 1875, 287 mills, 6457 workmen, and 98,615 spindles) and for wool-spinning and weaving (4893 machine and hand looms) is at MAZAMET (*q.v.*), but all sorts of woollen and cotton stuffs are produced in other localities. Other industrial products are woollen hosiery, cotton, silk, and linen thread, morocco, hats, earthenware, glass, soap; and there are tanneries, distilleries, flour-mills, breweries, dye-works, sawmills, printing-works, and numerous limekilns. In 1881 929 tons of steel and 1947 tons of iron of various kinds were produced. The Tarn is navigable for 43 miles; there are 208 miles of national roads, 4274 of other roads, and 120 of railway. The department forms the diocese of Albi, and belongs to the 16th corps d'armée (Montpellier), and the court of appeal is at Toulouse. The chef-lieu is Albi. There are 4 arrondissements (Albi, Castres, Gaillac, Lavaur), 35 cantons, and 318 communes.

TARN-ET-GARONNE, a department of southwestern France, was formed in 1808 of districts formerly belonging to Guienne and Gascony (Quercy, Lomagne, Armagnac, Rouergue, Agenais), with the addition of a small piece of Languedoc. From 1790 to 1808 it was divided between the departments of Lot, Haute-Garonne, Tarn, Aveyron, Gers, and Lot-et-Garonne. Lying between 43° 47′ and 44° 25′ N. lat. and 0° 55′ and 1° 58′ E. long., it is bounded on the N. by Lot, on the E. by Aveyron, on the S. by Tarn and Haute-Garonne, and on the W. by Gers and Lot-et-Garonne. The Garonne and its tributary the Tarn, unite a few miles below Moissac, and separate the elevated lands to the north, which belong to the Cevennes and the Central plateau, from those to the south, which are a continuation of the plateau of Lannemezan. The principal tributary of the Tarn on the right is the Aveyron, the affluents of which run through remarkably parallel valleys from northeast to southwest. The general slope of the department is from east to west; the highest point (1634 feet) is on the border of Aveyron, the lowest (164 feet) where the Garonne leaves it. The winter temperature is 37° F., that of spring and autumn 54° F., and that of summer 72° F. Rain falls seldom, but heavily, especially in spring, the annual rainfall being 28.9 inches.

Of a total area of about 1436 square miles, or 919,265 acres, arable land occupies 552,703 acres, meadows and grass 45,073, vineyards 102,849, woods 115,429, moorland and pasturage 41,819. The returns in 1883 showed 2,167,000 bushels of wheat, 35,062 of meslin, 62,975 of rye, 77,000 of barley, 2,722,500 of oats, 759,000 of maize, 1,867,250 of potatoes, 35,468 tons of beetroot, 172 tons 8 cwt. of colza seed, 399 tons of hemp, 394 tons of flax, 250,788 tons of fodder, 12 tons 15 cwt. of silk cocoons, 20,048,380 gallons of wine. The live stock in 1881 included 14,336 horses, 1680 mules, 2120 asses, 89,295 cattle of various descriptions, 116,349 sheep, 1358 goats, 32,375 pigs; 6347 beehives gave 25 tons 13 cwt. of honey and 8 tons 2 cwt. of wax. There are 57 quarries, employing 426 workmen, where phosphates of lime, lithographic stone, freestone, potters' clay, gypsum and schist for slating are worked, as are also iron and copper. The manufacturing industry is represented by flour-mills, various kinds of silk-mills (1317 workmen), and manufactories of linen, wool and paper. Much fruit is grown, and the principal exports are fresh fruit, wine, flour, phosphates, lithographic stone. There are 83 miles of waterway, including 48 of canal, 156 miles of national roads, 3515 of other roads, 127 of railway lines, the centre of which is Montauban. Tarn-et-Garonne is one of the least densely peopled departments of France: in 1886 there were 214,046 inhabitants, and their number is decreasing. Except some 10,000 Calvinists, all are Roman Catholics. The department forms the diocese of Montauban, and belongs to the jurisdiction of the Toulouse court of appeal and to the district of the 17th corps d'armée (Toulouse). It has 3 arrondissements (Montauban, Moissac and Castel-Sarrasin), 24 cantons and 194 communes.

---

[1] R. Yehudah Ibn Ḳoreish fully understood the value of the Targums. See his interesting epistle, addressed to the Jewish community of Fez, published at Paris (1857, 8vo), under the name of *Epistola de Studii Targum Utilitate*. A translation of the introductory part (by Wetzstein) is given in the *L. B. O.*, iii. col. 22 (reprinted by Dr. Berliner, *T. O.*, p. 168 *sq.*). Ibn Ḳoreish belonged to the 9th century, and not, as Berliner says, to the 10th or 11th; nor was he a Ḳaraite as Graetz (v. p. 293) half believes.

TARNOPOL, a market town in Galicia, Austria, on the Sereth. It was formerly a fortress, and rendered valuable services to Polish kings, who, in their turn, conferred upon it important privileges. The town enjoys a brisk trade in grain and wine, and has some sugar factories. Its yearly horse fairs are famous throughout the country. The population in 1885 was 27,000, about half of them Jews.

TARPAULIN is a waterproof sheeting consisting of a stout canvas cloth impregnated and coated with tar. It is employed for covering hatchways and other openings into the holds of vessels, for making covers for railway and other wagons and farm ricks, and generally for protecting bulky goods and structures from weather and damp. Many waterproof compositions other than tar are used for similar purposes, the principal ingredients being solutions of india-rubber, gutta-percha, and various resinous bodies combined with pigments. See Waterproofing.

TARQUINII. See Etruria, vol. viii., p. 557.

TARQUINIUS PRISCUS, Lucius, fifth legendary king of Rome, is represented as the son of a Greek refugee who removed from Tarquinii in Etruria to Rome, by the advice of his wife, the prophetess Tanaquil. Appointed guardian to the sons of Ancus Marcius, he succeeded in supplanting them on the throne on their father's death. It was he who first established the Circus Maximus, built the great cloacæ, and founded the triple temple on the Capitol,—the expense of these vast works being defrayed by plunder seized from the Latins and Sabines. Many of the ensigns both of war and of civil office are assigned to his reign, and he was the first to celebrate a Roman triumph, after the Etruscan fashion, in a robe of purple and gold, and borne on a chariot drawn by four horses. After a reign of thirty-eight years he was assassinated by the contrivance of the sons of Ancus Marcius, but Tanaquil had influence enough to secure the succession to Servius Tullius, his son-in-law. See vol. xx., p. 753.

TARQUINIUS SUPERBUS, Lucius, son of the preceding, and son-in-law of Servius Tullius, immediately succeeded the latter without any of the forms of election, and proceeded at once to repeal the recent reforms in the constitution, seeking to establish a pure despotism in their place. Wars were waged with the Latins and Etruscans, but the lower classes were deprived of their arms, and employed in erecting monuments of regal magnificence, while the sovereign recruited his armies from his own retainers and from the forces of foreign allies. The completion of the fortress temple on the Capitoline confirmed his authority over the city, and a fortunate marriage of his son to the daughter of Octavius Manilius of Tusculum secured him powerful assistance in the field. His reign was characterized by bloodshed and violence; the outrage of his son Sextus upon Lucretia precipitated a revolt, which led to the expulsion of the entire family, after Tarquin had reigned twenty-five years. All efforts to force his way back to the throne were vain, and he died a lonely and childless old man at Cumæ. See vol. xx., p. 754.

TARRAGONA, a maritime province in the northeast of Spain, with an area of 2451 square miles and a population in 1877 of 330,105, was formerly part of the province of Catalonia. It is bounded on the S.E. by the Mediterranean, on the N.E. by Barcelona, on the N. by Lerida (the Sierra de Almenar), on the W. by Saragossa and Teruel, and on the S.W. by Castellon-de-la-Plana. The Ebro flows through the southern portion of the province, and the other chief streams are the Gaya and the Francoli. The district, although mountainous, is the richest in Catalonia. The hills are clothed with vineyards, which produce excellent wines, and in the valleys are cultivated all kinds of grain, vegetables, rice, hemp, flax and silk. Olive, orange, filbert and almond trees reach great perfection, and the mountains yield rich pastures and timber trees of various kinds. Manufactures are well advanced, and comprise all textile fabrics, soap, leather and spirits. There are also several potteries and cooperages, and flour, paper and oil mills. Silver, copper, lead and barytes are plentiful, and quarries of marble and jasper are worked in the hills. The military government of the province is dependent on the captaincy-general of Catalonia. For administrative purposes the district is divided into eight partidos judicales, containing 186 ayuntamientos, and returns three senators and eight deputies to the cortes. Besides the capital, the towns in the province with more than 10,000 inhabitants are Reus (27,691), Tortosa (23,808) and Valls (13,256).

TARRAGONA, the capital of the above province, is a flourishing seaport, the seat of an archbishopric, at the mouth of the Francoli, 63 miles by rail west-southwest of Barcelona, in 41° 10′ N. lat. and 0° 20′ E. long., with a population of 23,046 in 1877. The picturesque but badly built older portion of the town stands on the steep slope of a hill 760 feet high, and is still surrounded by walls of Roman (in parts Cyclopean) origin. Below the walls a broad street, the Rambla, divides the upper from the lower town, which has been more regularly built in modern times along the low promontory which stretches out into the Mediterranean. The city is most beautifully situated, and gains considerably in effect from its magnificent cathedral, one of the noblest examples of early Spanish art. It is 300 feet in length and 100 feet in breadth, and consisted originally of a nave, aisles, transepts with an octagonal lantern at the crossing, and an apsidal chancel. Several exterior chapels have been added in later times, and on the southeast stands a 14th-century steeple raised on a Romanesque tower. The east end was probably begun in 1131 on the ruins of an earlier church, but the main body of the building dates from the end of the 12th century and the first half of the 13th, and is of transitional character,—the exuberant richness of the sculptured capitals being admirably kept in subordination by the Romanesque simplicity of the masses. Considerable changes were introduced at a later date; and the present west end of the nave cannot have been completed till late in the 14th century. On the northeast side is a cloister contemporary with the church, with which it communicates by a very fine doorway. The cloister contains much remarkable work, and the tracery of the windows bears interesting marks of Moorish influence. Two other noteworthy churches in the city are San Pablo and Santa Tecla la Vieja, both of the 12th century. The mole, begun in 1491, was chiefly constructed out of the Roman amphitheatre, of which a few rows of seats can still be seen on the sea-shore. The remains of a Roman aqueduct form a picturesque feature in the landscape. The Carcel de Pilatos is said to have been the palace of Augustus Cæsar; it was partly destroyed by Suchet, and now serves as a prison. The museum contains a collection of the Roman antiquities which are continually being discovered during excavations.

The trade is steadily increasing. During 1885 the vessels cleared amounted to 377,250 tons (45,795 tons British, 47,181 French, and 42,617 Swedish and Norwegian). The exports were valued at £1,289,533 [$6,267,130.38] (wine £1,023,847) [$4,975,896.42], and the imports at £1,237,012 [$6,173,878.32]. The exports were mostly to France, Great Britain, and the River Plate; the imports were chiefly from Germany, Russia, France, and Sweden. There is communication by rail with Barcelona, Valencia, and Lerida, and by steamer with other ports of Spain.

Tarraco was one of the earliest strongholds of the Romans in Spain, and became a colony (of Julius Cæsar), the capital of Hispania Citerior, and the richest town on the coast. To the Romans the Visigoths under Euric succeeded in 467, but on their expulsion by the Moors in 710 the city was razed to the ground. It was long before the ruins were again inhabited, but by 1089, when the Moors were driven out by Raymond IV. of Barcelona, there must have been a certain revival of prosperity, for the primacy, which had been removed to Vich, was in that year restored to Tarragona. In 1118 a grant of the fief was made to the Norman Robert Burdet, who converted the town into a frontier fortress against the Moors. In 1705 the city was taken and burned by the English, and a century later, after being partly fortified by them, it was captured and sacked by the French in 1811 under Suchet.

TARSHISH. See Phœnicia, vol. xviii, p. 819.

TARSUS, now Ṭarsús, an ancient city in the fertile plain of Cilicia, lay on both sides of the Cydnus, whose cool and swift waters were the pride of the city (Dio Chrys., vol. ii. p. 2, Reiske's ed.; *Vita Apollon.*, i. 7), and bore traffic to and from the port of Rhegma. In the time of Xenophon (*Anab.*, i. 2. 23) Tarsus was already great and flourishing and was the residence of the vassal king of Cilicia. Its civilization at this time seems to have been mainly Semitic, as was to be expected from the geographical relations of Cilicia, which have generally associated its history with that of Syria. We have coins of Tarsus (תרז) of the Persian period, bearing Aramaic inscriptions; and the deities of the town, known in later times as Heracles, Perseus, Apollo, Athena (Dio Chr., ii. 22), seem to have been akin to those of the Phœnicians and Syrians (see below). The Semitic influence was doubtless very ancient; indeed, the Assyrians invaded Cilicia in the 9th century B.C., at which date Tarsus is perhaps mentioned on the monuments under the name of Tarzi (Schrader, *Keilinschr. und Gesch.*, 1878, p. 240; the reading is not certain). After Tarsus was Hellenized the citizens learned to boast that they were Argives sprung from the companions of Triptolemus (Strabo, xiv. 5. 12; Dio Chr., ii. 20), and the town became the seat of a famous school of philosophy which was frequented almost exclusively by natives, but sent forth teachers as far as Rome itself.[1] More than one of these philosophers, notably Athenodorus the teacher of Augustus, and Nestor the teacher of Marcellus, held the chief magistracy of the city. Athenodorus and his predecessors were Stoics, but Nestor was an Academic (Strabo, xiv. 5. 14)[2] so that the Platonic philosophy is that with which Paul would probably have come in contact if he gave heed to the Greek wisdom of his native city. Presumably, however, he formed no higher opinion of the culture of Tarsus than did his contemporary Apollonius of Tyana, whose testimony as to the character of the citizens (*Vit. Ap.*, i. 7) is confirmed by Dio Chrysostom. Tarsus had made rapid material progress since Cilicia became Roman (66 B.C.). It was the capital of a rich province, and had received freedom from Antony, and from Augustus the dignity of a metropolis and important immunities for its commerce (Dio Chr., ii. 36). The inhabitants were vain, effeminate, and luxurious, more like Phœnicians than Greeks. Their sensuous Eastern religion in these golden days of affluence had more attraction for them than the grave philosophy of the Porch; and the legend supposed to be graven on the statue of Sardanapalus, at the neighbor city of Anchiale, "let us eat and drink, for to-morrow we die," which Paul quotes in 1 Cor. xv. 32, might have been the motto of the mass of the townsmen.[3] At Tarsus the emperor Tacitus died, and Julian was buried. The city was deserted and lay waste during the frontier wars of Greeks and Arabs in the first century of Islam; a Moslem general, who saw the ruins, estimated its former population at 100,000 (Beladhorí, p. 169). It was rebuilt and settled as a military colony and frontier post by Hárún al-Rashíd in 787 A.D., and became a starting point of forays against the Christians. On such a campaign the caliph Ma'mún died, and was buried at Tarsus (833), having caught a fever, like Alexander the Great, by bathing in the cold Cilician waters. Tarsus was temporarily recovered to Christendom by Nicephorus Phocas, and again by the crusaders under Baldwin. Finally it remained in the hands of the Turks.

The Heracles of Tarsus was the Cilician god Sandan. Dio Chrysostom calls him the ἀρχηγός of the Tarsians (ii. 23), and he may be identified with the Baal of Tarsus named on the coins already spoken of. He was worshipped by the periodical erection of "a very fair pyre" (*ibid.*), a rite presumably analogous to that described in the *De Dea Syria*, ch. 49; and the remarkable ruin of Dönük-tash, a vast court with massive walls enclosing two lofty platforms of concrete, probably marks the site of his sanctuary (see Perrot and Chipiez, *Hist. de l'Art*, iv. 536 *sq.*, and Langlois, *Voyage dans la Cilicie*, p. 265 *sq.*). A tradition making Sandan the founder of Tarsus is given by Ammianus (xiv. 8. 3); and, as the Greeks appear to have taken elements of the myth of Sandan (including the pyre) into their legend of Sardanapalus, this explains the current story that Sardanapalus founded Anchiale and Tarsus in one day (Arrian, ii, 5, 2; Athen., xii. p, 529 *sq.*). On Sandan, see K. O. Müller, in *Rhein. Mus.*, 1829, and E. Meyer, in *Z. D. M. G.*, 1877, p. 736 *sq.* Another account in Ammianus makes Perseus the founder of Tarsus, and it appears from Dio Chr. that he was almost or quite as much honored. The footprint of Pegasus was shown at Tarsus (Avienus, 1031 *sq.*; comp. Dio, ii. 24), and his ταρσός (wing ?) was said to have fallen there (Alex. Polyh. in Steph. Byz., *s.v.*). This worship reappears at Joppa. Apollo "with the trident" had a sacred sword at Tarsus, which could be cleansed only by the water of the Cydnus (Plut., *Def. Orac.*, 41), and is probably the same as the *harpe* shown on coins of Hadrian's time; if so, he is presumably a differentiated form of Perseus. The worship of Athena may be connected with the statement of Athenodorus (the famous philosopher of Tarsus) that the ancient name of the city was Parthenia (*Fr. Hist. Gr.*, iii. 487). Abydenus in Eusb., (*Chron.*, p. 35, ed. Schöne) ascribes the foundation of her temple with its brazen columns and of the city itself to Sennacherib. Thus with the Baal of Tyre there was worshipped an unmarried goddess, as in so many shrines of Syria and Asia Minor. Dio Chr., ii. 2, speaks also of Titans as lords of the city. The reference is to Japetus (Japhet ?), grandfather of Cydnus (Athenodorus, *ut sup.*).

TARTAGLIA, Niccolò (*c.* 1500–1557), a self-taught mathematician, was born at Brescia about 1500. His father, Michele Fontana, was a postal messenger between Brescia and the neighboring towns, who, dying in 1506, left two sons and a daughter to the care of their penniless mother. Niccolò's childhood was accordingly passed under the stress of dire poverty, and was marked by a cruel misfortune. During the sack of Brescia in 1512 he was, in the cathedral where he had vainly sought a refuge, horribly mutilated by some infuriated French soldiers. His skull was laid open in three places, his palate cloven, both jawbones fractured. Yet he recovered with no further assistance than his mother's patient care. He, however, long continued to stammer in his speech, whence the nickname, adopted by himself, of "Tartaglia." His education remains a mystery. Save for the barest rudiments of reading and writing, he tells us that he had no master; yet we find him at Verona in 1521 an esteemed teacher of mathematics. In 1534 he transferred his residence to Venice, and was there met by Antonio del Fiore with a challenge to one of the intellectual duels then customary. Del Fiore relied on his possession of an undivulged formula by Scipione del Ferro for the solution of a particular case of cubic equations. But Tartaglia had attained in 1530 a similar result, which he now, in February, 1535, greatly extended. His consequent triumph over his adversary gave him a high reputation, and his house became the resort of the learned of all grades and nations. The mystery in which he chose to shroud his method of dealing with cubic equations promised him a highly effective weapon in future contests, as well as leisure to perfect, before publishing, the coveted rules. But in 1539 Cardan enticed him to Milan, and there, by unremitting solicitations, procured from him the rude verses in which he had enshrined his discovery (see ALGEBRA, vol. i. p. 453). The Milanese physician's breach of his oath of secrecy gave rise to a bitter and lifelong quarrel, the most conspicuous incident in which was a public disputation at Milan, August 10, 1548, at which Cardan shrank from appearing. In 1548 Tartaglia accepted a situation as professor of Euclid at Brescia, but returned to Venice at the end of eighteen months. He died at Venice December 13, 1557. Acrid and emulous in disposition, he incurred abundant enmities; yet his honesty, uprightness, and the morality of his life remain unimpeached. He was keen-witted, diligent and ingenious, and by his discoveries in the solution of equations helped to initiate the rapid progress of modern mathematics.

---

[1] To Strabo's list must be added Zeno, the successor of Chrysippus.

[2] Lucian, *Macrob.*, 21, makes him a Stoic and teacher of Tiberius.

[3] Athenæus, v. p. 215, tells of an Epicurean philosopher, Lysias, who, becoming priest of Heracles, became tyrant of the city, taxing the rich to provide largesses for the poor. The fact is probable, the date quite uncertain.

Tartaglia's first printed work, entitled *Nova Scientia* (Venice, 1537), dealt with the theory and practice of gunnery, to which his attention had been drawn in 1531 by the question of a bombardier at Verona as to the elevation giving the greatest range. He easily found it to be 45° (true only *in vacuo*), but failed to demonstrate the correctness of his intuition. Indeed, he never shook off the erroneous ideas of his time regarding the paths of projectiles, further than to see that no part of them could be a straight line. He nevertheless inaugurated the scientific treatment of the subject, and his propositions reappeared in most ballistical treatises down to Blondel's in 1683. The publication of the *Nova Scientia* was determined by the menacing attitude of Soliman II. Unless in the interest of Christendom, Tartaglia regarded it as a crime to promote arts of destruction. Inquiries rendered lawful by necessity were, however, resumed in his *Quesiti et Invenzioni Diverse*, a collection of the author's replies to questions addressed to him by persons of the most varied conditions, published in 1546, with a dedication to Henry VIII. of England. Problems in artillery occupy two out of nine books; the sixth treats of fortification; the ninth gives several examples of the solution of equations of the third degree. His last years were full of activity. He published in 1551 *Regola Generale per sollevare ogni affondata Nave, intitolata la Travagliata Invenzione* (an allusion to his personal troubles at Brescia), setting forth a method for raising sunken ships, and describing the diving-bell, then little known in western Europe. He pursued the subject in *Ragionamenti sopra la Travagliata Invenzione* (May, 1551), adding a table of specific gravities. Of his largest work, entitled *Generale Trattato di Numerie Misure*, two parts appeared at Venice in 1556, the remaining four posthumously in 1560. This is a comprehensive mathematical treatise, including arithmetic, geometry, mensuration, and algebra as far as quadratic equations. He designed to embody the results of his original investigations in a separate form; but his *Algebra Nova* remained unwritten. He published the first Italian translation of Euclid (1543) and the earliest version from the Greek of some of the principal works of Archimedes (1543). These included the tract *De Insidentibus Aquæ*, of which his Latin now holds the place of the lost Greek text. An Italian version of it is appended to his *Ragionamenti*. Tartaglia was the first Italian writer on fortification, and claimed the invention of the gunner's quadrant.

Tartaglia's own account of his early life is contained in his *Quesiti*, lib. vi. p. 74. See also Bittanti's *Discorso di Niccolò Tartaglia*, Brescia, 1871; Buoncompagni, *Intorno ad un Testamento inedito di N. Tartaglia*, Milan, 1881; Libri, *Hist. des Sciences Mathématiques*, t. iii. p. 149; Montucla, *Hist. des Math.*, vol. i. p. 567; Marie, *Hist. des Sciences*, t. ii. p 242; Hankel, *Zur Gesch. d. Math.*, 1874, p. 360; Rossi, *Elogi di Bresciani Illustri*, p. 386. Tartaglia's writings on gunnery were translated into English by Lucar in 1588, and into French by Rieffel in 1845. Thos. Salusbury published (London, 1564) an English version of his *Travagliata Invenzione*, and a selection from his writings appeared at Venice in 1606 with the title *Opere del Famosissimo Niccolò Tartaglia*, 1 vol. 8vo.

TARTAN is a worsted cloth woven with alternate stripes or bands of colored warp and weft, so as to form a chequered pattern in which the colors alternate in "sets" of definite width and sequence. The weaving of particolored and striped cloth cannot be claimed as peculiar to any special race or country, for indeed such checks are the simplest ornamental form into which dyed yarns can be combined in the loom. But the term tartan is specially applied to the variegated cloth used for the principal portions of the distinctive costume of the Highlanders of Scotland. For this costume, and the tartan of which it is composed, great antiquity is claimed, and it is asserted that the numerous clans into which the Highland population were divided had each from time to time a special tartan by which it was distinguished. After the rebellion of 1745 various Acts of Parliament were passed for disarming the Scottish Highlanders and for prohibiting the use of the Highland dress in Scotland, under severe penalties. These Acts remained nominally in force till 1782, when they were formally repealed, and since that time clan tartan has, with varying fluctuations of fashion, been a highly popular article of dress, by no means confined in its use to Scotland alone; and many new and imaginary "sets" have been invented by manufacturers, with the result of introducing confusion in the heraldry of tartans, and of throwing doubt on the reality of the distinctive "sets" which at one time undoubtedly were more or less recognized as the badge of various clans. The manufacture has long been carried on at Bannockburn, in the neighborhood of Stirling, and it still continues to be a feature of the local industries there.

Undoubtedly the term tartan was known, and the material was woven, "of one or two colors for the poor and more varied for the rich," as early as the middle of the 15th century. In the accounts of John, bishop of Glasgow, treasurer to King James III. in 1471, there occurs, with other mention of the material, the following: "Ane elne and ane halve of blue Tartane to lyne his gowne of cloth of Gold." It is here obvious that the term is not restricted to particolored chequered textures.[1] In 1538 accounts were incurred for a Highland dress for King James V., on the occasion of a hunting excursion in the Highlands, in which there are charges for "varient cullorit velvet," for "ane schort Heland coit," and for "Heland tartane to be hose to the kinge's grace." Bishop Lesley, in his *De Origine, Moribus, et Rebus Gestes Scotorum*, published in 1578, says of the ancient and still-used dress of the Highlanders and islanders, "all, both noble and common people, wore mantles of one sort (except that the nobles preferred those of several colors)." George Buchanan, in his *Rerum Scoticarum Historia* (1582), as translated by Monypenny (1612), says of the Highlanders, "they delight in marled clothes, especially that have any long stripes of sundry colors; they love chiefly purple and blue. Their predecessors used short mantles or plaids of divers colors sundry ways divided; and amongst some the same custom is observed to this day." A hint of clan tartan distinctions is given by Martin in his *Western Isles of Scotland* (1703), which work also contains a minute description of the dress of the Highlanders and the manufacture of tartan. "Every isle," he observes, "differs from each other in their fancy of making plaids, as to the stripes in breadth and colors. This humor is as different through the mainland of the Highlands, in so far that they who have seen those places is able at the first view of a man's plaid to guess the place of his residence."

See W. and A. Smith, *Tartans of the Clans of Scotland*, 1850; J. Sobieski Stuart, *Vestiarium Scoticum*, 1842; R. R. M'Ian, *Clans of the Scottish Highlands*, 1845–46; J. Grant, *Tartans of the Clans of Scotland*, Edinburgh, 1885.

---

[1] Neither so is it in the French *tiretaine* or in the Spanish *tiritaña*.

TARTARIC ACID, in its ordinary acceptation, refers to one acid, $(C_4H_4O_6)H_2$, which occurs in most acid fruit juices, in association generally with malic or citric, or both. Grape-juice owes its sourness almost entirely to acid tartrate of potash. While the juice ferments into wine, the greater part of the acid tartrate separates out, along with tartrate of lime, coloring matter, and other impurities, as a hard crust adhering to the sides of the cask. Such impure acid tartrate of potash is known commercially as "argol." It was known to the Greeks as τρύξ, to the Romans as *fæx vini*. The alchemists from the 11th century called it *tartarus*, which name has survived in familiar chemical parlance to this day. The true constitution of *tartarus vini* was discovered by Scheele in 1769. He was the first to isolate the acid from its acid potash salt by a method which is still used for its industrial extraction.

Manufacture.—Crude tartar (10 to 14 cwts.) is placed in a tank, and dissolved in sufficient water with the help of steam. The surplus acid is then neutralized by addition of powdered chalk, and precipitated as lime salt :

$$2(C_4H_4O_6)KH = \underset{\text{normal salt.}}{(C_4H_4O_6)K_2} + \underset{\text{acid.}}{(C_4H_4O_6)H_2};$$

$$(C_4H_4O_6)H_2 + Ca\,CO_3 = (C_4H_4O_6)Ca + H_2O + CO_2.$$

The other half of the tartaric acid which remains dissolved as normal potash salt is then precipitated in the same form by addition of chloride of calcium :

$$(C_4H_4O_6)K_2 + CaCl_2 = 2KCl + (C_4H_4O_6)Ca.$$

The tartrate of lime precipitate is collected, washed, and decomposed by an excess of sulphuric acid at 75° C.:

$$(C_4H_4O_6)Ca + H_2SO_4 = CaSO_4 + (C_4H_4O_6)H_2.$$

The sulphate of lime is removed by decanting and filtering, and the acid solution evaporated in leaden pans to a sufficient degree to deposit crystals on standing in the cold. The crystals are purified by redissolving them in hot water, decolorizing the solution with animal charcoal, and causing the acid to crystallize a second time after addition of sulphuric acid, which promotes the formation of large crystals. The crystals contain a little sulphuric acid and a trace of lead; if intended for internal use, they must be recrystallized from pure water.

Tartaric acid forms hard colorless transparent monoclinic prisms of 1.764 spec. grav., easily soluble in cold and abundantly in hot water. It has a strong but agreeable sour taste. At 15° C. [59° F.] 100 parts of water dissolve 138 parts of the acid, 100 of alcohol (absolute) 20.4, and 100 of ether 0.39. It fuses at 135° C. [275° F.], and passes into an amorphous modification known as meta-tartaric acid; when heated more strongly it loses water, and passes into the forms of anhydrides. At high temperatures it is decomposed with formation of charcoal and volatile products, which smell pretty much like those formed from sugar in the same circumstances. Most oxidizing agents produce formic from the aqueous acid. Boiling with oxide of silver and excess of caustic alkali produces oxalate.

Tartaric acid is used largely in calico printing as a discharge. In pharmacy and households it serves, conjointly with bicarbonate of soda or potash, for the extemporaneous preparation of effervescing drinks. The so-called German effervescing powders are a combination of weighed-out doses of tartaric acid and of bicarbonate of soda. In the so-called "seltzogènes" (glass apparatus in which carbonic acid is produced in one compartment, to be forced by its own pressure into a mass of water, wine, etc., in the other) the gas is similarly produced.

Tartrates.—The *acid potash salt*, $(C_4H_4O_6)HK$, "cream of tartar," is prepared from crude tartar (argol) by dissolving it in hot water, filtering off what remains of tartrate of lime and other impurities, and allowing the filtrate to crystallize. The crystals are generally contaminated with a little of the lime-salt, for the removal of which the best method is to treat the powdered crystals with cold dilute hydrochloric acid and then wash them with cold water by displacement. The lime passes into the filtrate. Cream of tartar forms small colorless hard crystals which dissolve in about 200 parts of cold and in 15 parts of boiling water. In alcohol the salt is even less soluble than in water.

The *normal* (neutral) *potash salt* $(C_4H_4O_6)K_2 + \frac{1}{2}H_2O$, is prepared by dissolving powdered cream of tartar in hot solution of carbonate of potash until a neutral or slightly alkaline solution is produced. The salt, being extremely soluble in water, does not crystallize very readily. In former times the carbonate of potash required used to be made by igniting one half of the cream of tartar to be operated upon in a crucible. Hence the name of *tartarus tartarisatus*, which is still familiar in pharmacy. The salt is used medicinally, and also for removing free acid from excessively sour wine by formation of relatively insoluble bitartrate (Liebig's method).

Rochelle salt, $(C_4H_4O_6)KNa + 4H_2O$, is prepared by not quite neutralizing hot solution of carbonate of soda with powdered cream of tartar. The (filtered) hot solution deposits on cooling magnificent crystals, readily soluble in water, though less so than the unmixed potash salt. Rochelle salt is used as a mild purgative. The so-called Seidlitz powders are effervescing powders with a considerable addition of Rochelle salt to the bicarbonate.

The normal tartrates of lime, baryta, etc., are insoluble precipitates producible by double decompositions.

Tartar emetic, $(C_4H_4O_6)K(SbO) + \frac{1}{2}H_2O$, is produced by boiling 4 parts of oxide of antimony, Sb_2O_3, and 5 of powdered cream of tartar with 50 of water for about an hour. The filtered solution, on cooling, deposits crystals of the above composition soluble in 15 parts of cold and 2.8 of boiling hot water. The crystals generally exhibit the appearance of tetrahedra ; yet they are rhombic prisms combined with pyramids. The process going on in the formation of the salt is easily understood if we remember that Sb_2O_3, often acts on aqueous acids as if it were the monoxide, $(SbO)_2O$, of a radical (SbO) antimonyl. $(SbO)_2O + H_2O$ is equivalent to $2(SbO)OH$, and

$$(C_4H_4O_6)KH + OH(SbO) = H_2O + (C_4H_4O_6)K(SbO).$$

Tartar emetic has long had a standing in medicine. In doses of 1–3 grains it acts as a powerful emetic; very small doses ($\frac{1}{80}$ to $\frac{1}{10}$ grain) induce perspiration. Large doses produce poisonous effects.

Analysis.—Tartaric acid is characterized chiefly by the relative insolubility of its acid potash salt. To produce it from a solution of a neutral tartrate, add acetic acid and acetate of potash, and stir vigorously; the salt gradually separates out as a crystalline precipitate. Neutral tartrate solutions, with chloride of calcium, give a precipitate of tartrate of lime, which is at first amorphous, and in this condition dissolves pretty readily in excess of reagent or tartrate, but in general re-separates in the crystalline form (the undissolved tartrate likewise becomes crystalline) on standing.

Anhydrides.—Tartaric acid, when kept at 135° [275° F.], fuses and becomes meta-tartaric acid without change of weight, and on continued application of 140–150° C. [284°–302° F.], ditartrylic acid, $C_8H_{10}O_{11} = 2C_4H_6O_6 - H_2O$; and at 180° [356° F.] tartrelic acid, $C_8H_8O_{10} = 2C_4H_6O_6 - 2H_2O$, is produced. All these three acids form salts of their own, which, however, tend to become tartrates in the presence of water. At 180° [356° F.] real tartaric anhydride (like tartrelic, $C_8H_8O_{10} = 2C_4H_4O_5$) is produced, in addition to tartrelic acid, as an infusible yellowish mass, insoluble in water and in ether. By continued contact with water it is converted finally into tartaric acid solution.

Isomeric Modifications.—Among these *racemic acid* has long been known as an occasional bye-product in the manufacture of tartaric acid. It used to be believed that racemic acid is present ready formed in certain grape-juices, and thus comes to make its appearance occasionally; but it is well known now that the bulk of it at any rate is produced from what was originally tartaric acid, by the continued action of high temperatures and water. Racemic acid is almost identical with tartaric acid; the only purely chemical point of difference is that corresponding salts of the two acids often crystallize with different proportions of water. The two acids, however, are easily distinguished by their action on polarized light (see POLARITY, vol. xix. p. 326). A solution of tartaric acid turns the plane of polarization to the right; racemic acid is, in this sense, optically inactive. These long-known facts led Pasteur to the discovery of the true relations of the two acids. If the double racemate, $(C_4H_4O_6)Na(NH_4)$, is allowed to crystallize slowly, two kinds of crystals are produced, both bearing hemiedric faces, but differing from each other in the situation of these, exactly as the right hand differs from the left. Pasteur separated the two kinds of crystals, and found that one kind is identical with the ordinary (dextro-) tartrate of soda and ammonia, while the other contains a new kind of tartaric acid, which he called lævo-tartaric acid, because it turns the plane of polarization to the left. Equal weights of the two acids, when dissolved separately in water and mixed, unite, with perceptible evolution of heat, into optically neutral racemic acid. Racemic acid, then, is lævo- and dextro-tartaric united (loosely) into one molecule. There are a number of optically inactive tartaric acids, not susceptible of decomposition in the sense in which racemic acid is. (W. D.)

TARTARS (more correctly TATARS, but Tartars is the form generally current), a name given to nearly three million inhabitants of the Russian empire, chiefly Moslem and of Turkish origin. The majority—in European Russia—are remnants of the Mongol invasion of the 13th century (see MONGOLS), while those who inhabit Siberia are survivals of the once much more numerous Turkish population of the Ural-Altaic region, mixed to some extent with Finnish and Samoyedic stems, as also with Mongols. The name is derived from that of the Ta-ta Mongols, who in the 5th century inhabited the northeastern Gobi, and, after subjugation in the 9th century by the Tungus Kidañs, migrated southward, there founding the Mongolian empire under JENGHIZ KHAN (*q.v.*). Under the leadership of his grandson (Batu) they moved westwards, driving with them many stems of the Turkish Ural-Altaians towards the plains of Russia. The ethnographical features of the present Tartar inhabitants of European Russia, as well as their language, show that they contain no admixture (or very little) of Mongolian blood, but belong to the Turkish branch of the Ural-Altaic stock, necessitating the conclusion that only Batu, his warriors, and a limited number of his followers were Mongolians, while the great bulk of the 13th-century invaders were Turks. On the Volga they mingled with remnants of the old Bulgarian Turkish empire, and elsewhere with Finnish stems, as well as with remnants of the ancient Italian and Greek colonies in Crimea and Caucasians in Caucasus. The name of Tatars, or Tartars, given to the invaders, was afterwards extended so as to include different stems of the same Turkish branch in Siberia, and even the bulk of the then little known inhabitants of the high plateau of Asia and its northwestern slopes, which was described under the general name of Tartary. This last name has almost disappeared from geographical literature, but the name Tartars, in the above limited sense, remains in full use.

The present Tartar inhabitants of the Russian empire form three large groups,—those of European Russia and Poland, those of Caucasus, and those of Siberia. The discrimination of the separate stems included under the name is still far from completion. The following subdivisions, however, may be régarded as established: (1) The Kazañ Tartars, descendants of the Kiptchaks settled on the Volga in the 13th century, where they mingled with survivors of the Bulgar Turks and partly with Finnish stems. They number about half a million in the government of Kazañ, about 100,000 in each of the governments of Ufa, Samára, and Simbirsk, and about 300,000 in Vyatka, Saratoff, Tamboff, Penza, Nijni-Novgorod, Perm, and Orenburg; some 15,000 belonging to the same stem have migrated to Ryazañ, or have been settled as prisoners in the 16th and 17th centuries in Lithuania (Vilna, Grodno, and Podolia); and there are some 2000 in St. Petersburg. In Poland they constitute 1 per cent. of the population of the district of Płock. The Kazañ Tartars speak a pure Turkish dialect; they are middle-sized, broad-shouldered, and strong, and mostly have black eyes, a straight nose, and salient cheek bones. They are Mohammedans; polygamy is practiced only by the wealthier classes and is a waning institution. Excellent agriculturists and gardeners, very laborious, and having a good reputation for honesty, they live on the best terms with their Russian peasant neighbors. It may be added that, according to M. Yuféroff (*Étude éthn. sur les Bachkirs*, 1881), those Bashkirs who live between the Kama, Ural, and Volga are not of Finnish origin, but in virtue of their history, language, anthropological features, and customs must be regarded as Tartars. (2) The Astrakhan Tartars about 10,000 are, with the Mongol Kalmucks, all that now remains of the once so powerful Astrakhan empire. They also are agriculturists and gardeners; while some 12,000 Kundrovsk Tartars still continue the nomadic life of their ancestors. (3) The Crimean Tartars, who occupied the Crimea in the 13th century, have preserved the name of their leader, Nogai. During the 15th, 16th, and 17th centuries they constituted a rich empire, which prospered until it fell under Turkish rule, when it had to suffer much from the wars fought between Turkey and Russia for the possession of the peninsula. The war of 1853 and the laws of 1860-63 and 1874 caused an exodus of the Crimean Tartars; they abandoned their admirably irrigated fields and gardens and moved to Turkey, so that now their number falls below 100,000. Those of the south coast, mixed with Greeks and Italians, are well known for their skill in gardening, their honesty, and their laborious habits, as well as for their fine features, presenting the Tartar type at its best. The mountain Tartars closely resemble those of Caucasus, while those of the steppes—the Nogais—are decidedly of a mixed origin from Turks and Mongolians.

The Tartars of Caucasus, who inhabit the upper Kubañ, the steppes of the lower Kuma and the Kura, and the Araxes, number about 1,350,000. Of these (4) the Nogais on the Kuma show traces of an intimate mixture with Kalmucks. They are nomads, supporting themselves by cattle-breeding and fishing; few are agriculturists. (5) The Karatchais (18,500) in the upper valleys about Elburz live by agriculture. (6) The mountain Tartars (about 850,000), divided into many tribes and of an origin still undetermined, are scattered throughout the provinces of Baku, Erivan, Tiflis, Kutais, Daghestan, and partly also of Batum. They are certainly of a mixed origin, and present a variety of ethnological types, all the more so as all who are neither Armenians nor Russians, nor belong to any distinct Caucasian tribe, are often called Tartars. As a rule they are well built and little behind their Caucasian brethren. They are celebrated for their excellence as gardeners, agriculturists, cattle-tenders, and artisans. Although most fervent Shi'ites, they are on very good terms both with their Sunnite and with their Russian neighbors. Polygamy is rare with them, and their women go to work unveiled.

The Siberian Tartars, mostly mixed with Finnish stems, are the most difficult to classify. They occupy three distinct regions,—a strip running west to east from Tobolsk to Tomsk, the Altai and its spurs, and South Yeniseisk. They originated in the agglomerations of Turkish stems which in the region north of the Altai succeeded the Ugro-Samoyedic civilization (see SIBERIA), and reached a relatively high degree of culture between the 4th and the 8th centuries, but were subdued and enslaved by the Mongols. In the meantime the following subdivisions of the Siberian Tartars may be accepted; (7) The Baraba Tartars, who take their name from one of their stems (Barama), number about 50,000 in the government of Tobolsk and about 5000 in Tomsk. After a strenuous resistance to Russian conquest, and much suffering at a later period from Kirghiz and Kalmuck raids, they now live by agriculture, either in separate villages or along with Russians. (8) The Tcholym or Tchulym Tartars on the Tcholym and both the rivers Yus speak a Turkish language with many Mongolian and Yakut words, and are more like Mongols than Turks. In last century they paid a tribute for 2550 arbaletes, but they now are rapidly becoming fused with Russians. (9) The Abakan or Minusinsk Tartars occupied the steppes on the Abakan and Yus in the 17th century, after the withdrawal of the Kirghizes, and represent a mixture with Koibals (whom Castrén considers as partly of Ostiak and partly Samoyedic origin) and Beltirs—also of Finnish origin. Their language is also mixed. They are known under the name of Sagais, who numbered 11,720 in 1864, and are the purer Turkish stem of the Minusinsk Tartars, Koibals, and Kyzyl or Red Tartars. Formerly Shamanists, they now are, nominally at least, adherents of the Greek Orthodox Church, and support themselves mostly by cattle-breeding. Agriculture is spreading but slowly among them; they still prefer to plunder the stores of bulbs of *Lilium Martagon*, *Pæonia*, and *Erythronium Dens canis* laid up by the steppe mouse (*Mus socialis*). The Soyotes, or Soyons, of the Sayan Mountains, who are Finns mixed with Turks, the Uryankhes of northwest Mongolia, who are of Turkish origin but follow Buddhism, and the Karagasses, also of Turkish origin but much like the Kirghizes, and reduced now to a few hundreds, are akin to the above. (10) The Tartars of the northern slopes of the Altai (nearly 20,000 in number) are of Finnish origin. They comprise some hundreds of Kumandintses, the Lebed

Tartars, the Tchernevyie or Black-Forest Tartars, and the Shors (11,000), descendants of the Kuznetsk or Iron-Smith Tartars. They are chiefly hunters, passionately loving their *taiga*, or wild forests, and have maintained their Shaman religion and tribal organization into *suoks*. They live partly also on cedar-nuts and honey collected in the forests. Their dress is that of their former rulers, the Kalmucks, and their language contains many Mongolian words. (11) The Altai Tartars, or "Altaians," comprise—(*a*) the Mountain Kalmucks (12,000), to whom this name has been given by mistake, and who have nothing in common with the Kalmucks except their dress and mode of life, while they speak a Turkish dialect, and (*b*) the Teleutes, or Telenghites (5800), a remainder of a formerly numerous and warlike nation who have migrated from the mountains to the lowlands, where they now live along with Russian peasants.

Finally, there are a number of Tartars in Turkestan and Central Asia. Without including under this name the Sarts and the Kuramintses of Turkestan, still less the Kirghiz-Kazaks, it may be reckoned that there are still nearly 30,000 survivors of the Uigurs in the valley of the Ili, about Kuldja, and in the Khami oasis.

As is evident from the above, although the name Tartars originated in an indiscriminate application of the word to the Turkish and Mongolian stems which invaded Europe six centuries ago, and its gradual extension to the Turkish stems mixed with Mongolian or Finnish blood in Siberia, it still represents an aggregate of characters which warrant at least a provisional use of this genetic name, if those to whom it is given are properly subdivided. It embodies stems which, although widely distinct, still have some common ethnographical and philological features, besides being to some extent of like origin and history.

The literature of the subject is very extensive, and bibliographical indexes may be found in the *Geographical Dictionary* of P. Semenoff, appended to the articles devoted respectively to the names given above, as also in the yearly *Indexes* by M. Mezhoff. Besides the well-known works of Castrén, which are a very rich source of information on the subject, Schiefner (St. Petersburg academy of science), Donner, Ahlqvist, and other explorers of the Ural-Altaians, as also those of the Russian historians Solovieff, Kostomaroff, Bestuzheff-Riumin, Schapoff, and Ilovaiskiy, the following containing valuable information may be mentioned: the publications of the Russian Geographical Society and its branches; the Russian *Etnographicheskiy Sbornik;* the *Izvestia* of the Moscow society of the amateurs of natural science; the works of the Russian ethnographical congresses; Kostroff's researches on the Siberian Tartars in the memoirs of the Siberian branch of the geogr. soc.; Radloff's *Reise durch den Altai*, *Aus Sibirien;* "Picturesque Russia" (*Jivopisnaya Rossiya*); Semenoff's and Potanin's "Supplements" to Ritter's *Asien;* Harkavi's report to the congress at Kazañ; Hartakhai's "Hist. of Crimean Tatars," in *Vyestnik Evropy*, 1866 and 1867; "Katchinsk Tartars," in *Izvestia Russ. Geogr. Soc.*, xx, 1884. (P. A. K.)

TARTARUS, in the *Iliad* (viii. 13 *sq.*, 481), is a dark underground prison with iron gates, as far below Hades as earth is below heaven, whither Cronus and the Titans were thrust down by Zeus (vol. xxi. p. 336), and to which the sovereign of Olympus threatens to consign other gods who may disobey his behests. Later writers make Tartarus the place of punishment of the wicked after death. Æneas, in his visit to the abode of the shades, comes to a point where the road divides, the branch to the right leading to Elysium and that on the left to the prison-house of Tartarus, girt about by a triple wall, with the fiery Phlegethon as a moat, and guarded by the fury Tisiphone (*Æn.*, vi. 540 *sq.*). Tartarus is personified as the son of Æther and Ge, and father of the giants Typhoeus and Echidna.

TARTINI, Giuseppe (1692–1770), violinist, composer, and musical theorist, was born at Pirano, April 12, 1692, and in early life studied, with equal want of success, for the church, the law courts, and the profession of arms. His life as a young man was wild and irregular, and his temper extremely violent and impulsive. His unfitness for an ecclesiastical career was manifest; and, after failing in jurisprudence, he crowned his improprieties by clandestinely marrying the niece of Cardinal Cornaro, archbishop of Padua. Though the family of Tartini had been legally ennobled, the cardinal resented the marriage as a disgraceful mésalliance, and denounced it so violently that the unhappy bridegroom, thinking his life in danger, fled for safety to a monastery at Assisi, where, calmed by the soothing influence of the religious life, his character underwent a complete change. Docile and obedient, as he had before been passionate and headstrong, he studied the theory of music under Padre Boemo, the organist of the monastery, and, without any assistance whatever, taught himself to play the violin in so masterly a style that his performances in the church became the wonder of the neighborhood. For more than two years his identity remained undiscovered, but one day the wind blew aside a curtain behind which he was playing, and one of his hearers recognized him and betrayed his retreat to the cardinal, who, hearing of his changed character, readmitted him to favor and restored him to his wife.

Tartini next removed to Venice, where the fine violin-playing of Veracini excited his admiration and prompted him to repair, by the aid of good instruction, the shortcomings of his own self-taught method. After this he studied for some time at Ancona; and here, about 1714, he made the curious acoustical discovery on which his fame as a theorist chiefly rests. He observed that, when two notes are sounded together on the violin with sufficient intensity, a third sound, distinct from both, is simultaneously produced. For the production of this "third sound," as he called it, Tartini failed to account on strict mathematical principles. When the two primary notes form an impure consonance, the "third sound" of Tartini (now known as a difference tone of the first order) is accompanied by beats due to the presence of different tones of higher orders, the existence of which, unknown of course to Tartini, has been established by Helmholtz. Tartini made his observation the basis of a theoretical system which he set forth in his *Trattato di Musica, secondo la vera scienzia dell' Armonia* (Padua, 1754) and *Dei Principij dell' Armonia Musicale* (Padua, 1767). In 1721 he returned to Padua, where he was appointed solo violinist at the church of San Antonio. From 1723 to 1726 he acted as conductor of Count Kinsky's private band, but afterwards returned to his old post at Padua, where he died on February 16, 1770.

Tartini's compositions are very numerous, and faithfully illustrate his passionate and masterly style of execution, which surpassed in brilliancy and refined taste that of all his contemporaries. He frequently headed his pieces with an explanatory poetical motto, such as "Ombra cara," or "Volgete il riso in pianto o mie pupille." Concerning that known as *Il Trillo del Diavolo*, or *The Devil's Sonata*, he told a curious story to Lalande, in 1766. He dreamed that the devil had become his slave, and that he one day asked him if he could play the violin. The devil replied that he believed he could pick out a tune, and thereupon he played a sonata so exquisite that Tartini thought he had never heard any music to equal it. On awaking, he tried to note down the composition, but succeeded very imperfectly, though the resulting *Devil's Sonata* is one of his best and most celebrated productions.

Besides the theoretical works we have mentioned, Tartini wrote a *Trattato delle Appogiature*, posthumously printed in French, and an unpublished work, *Delle Ragioni e delle Proporzioni*, the MS. of which has been lost.

TARUDANT. See Morocco, vol. xvi. p. 856.

TASHKEND, or Tashkent, one of the largest and most important cities of Central Asia, now the capital of Russian Turkestan, is situated in the valley of the Tchirtchik, some 50 miles above its junction with the Syr-Daria, in 41° 20′ N. lat. and 69° 18′ E. long. The city, formerly enclosed by walls which are now ruinous, is surrounded by rich gardens, and its houses are buried among the fruit and other trees which grow all along the numberless ramifications of the irrigation canals. The buildings, which are of stone and sun-dried bricks, are mostly low, on account of the earthquakes which frequently disturb the region. Like all old cities of Asia, Tashkend is subdivided into sections (*yurts*), which are characterized by the special trades carried on in each. Asiatic Tashkend in 1871 had 78,130 inhabitants, mostly Sarts (75,176), with a few Uzbegs, Kirghizes, Jews, Russians, and Germans.

A depression in the southeast is occupied by Russian Tashkend, dating from 1865, which has clean, broad streets lined with poplars, the low nice-looking houses being surrounded by gardens. In 1875 its population, exclusive of the military, was 4860, mostly Russians. It has a public library containing a rich collection of works on Central Asia, an observatory, a museum, two gymnasia, a seminary, and the buildings occupied by the administration. A branch of the Russian Geographical Society has been opened at Tashkend, and its publications, as also those of the statistical committee and the *Turkestan Gazette*, contain most valuable information about Turkestan. According to the most recent estimates, the population of Tashkend, with its suburbs, is reckoned at 100,000. In consequence of the chequered history of the town (see TURKESTAN), few old buildings have been preserved, and only the madrasah Beklar Bek, with its fifty students, and the graves of Sheikh Zenedjin-baba and Zenghi-ata are worthy of mention. The former is four centuries old, and that of Zenghi-ata, a saint held in high veneration throughout Central Asia, yearly attracts thousands of pilgrims.

A variety of petty trades are carried on in numerous small workshops,—weaving and dyeing of cottons and the manufacture of small brass and iron wares, of harness, and especially of boots, being the chief. Most of the inhabitants are also engaged in raising corn, rice, oil plants, cotton, wine and lucerne, and in gardening. The trade of Tashkend has lost its former importance, but corn, cattle, silk, cotton, and fruits are still exported, and all kinds of manufactured wares are imported from the countries to the south.

TASMAN, ABEL JANSZEN (*c.* 1602–1659), a distinguished Dutch navigator, born at Hoorn, North Holland, probably in 1602 or 1603. He is known to have made two important voyages of discovery in the Pacific and Southern Oceans; only of the second of them have we a full account. In June, 1639, Tasman, along with Matthew Quast, was dispatched by Van Diemen, governor-general of the Dutch East Indies, on a voyage to the Western Pacific, which was first directed to the Philippine Islands; part of the coast of Luzon was explored. Sailing east and north Tasman and Quast touched at several of the Bonin Islands, which they were probably the first to discover. Sailing still farther north, in quest of what were then known as the "islands of gold and silver," they reached the latitude of 38° 40′ N., about 600 miles east of Japan, and continued east for other 300 miles on the parallel without discovering anything. On October 15 the navigators decided to return, and after touching at Japan, anchored at Taiwan-fu, Formosa, November 21. After this, Tasman was engaged in operations in the Indian seas until 1642, when he set out on his first great expedition.[1] Several Dutch navigators had already discovered various portions of the west coast of Australia, and the Dutch East India Company were anxious to obtain a more accurate and extended survey of that land. Sailing from Batavia on August 14, 1642, with two vessels the "Heemskirk" and "Zeehaan," Tasman on November 24 sighted the land to which he gave the name of Van Diemen, in honor of the governor-general, but which is now named Tasmania. He doubled the land, which he evidently did not know was an island, and running up Storm Bay, anchored on December 1 in the bay to which he gave the name of Frederick Henry. There he set up a post on which he hoisted the Dutch flag. Quitting Van Diemen's land on December 5, Tasman steered eastwards with a vague idea of reaching the Solomon Islands, and on December 13 he discovered a "high mountainous country," which he called "Staatenland" (New Zealand). Cruising along the west coast of the South Island, he anchored on the 18th in 40° 50′ S. lat., at the entrance of a "wide opening," which he took to be a "fine bay," but which was no doubt Cook's Strait. He gave the name of Moordenaars (Massacre) Bay to the bay, at which he attempted to land, and where several of his men were killed by the natives. Leaving New Zealand, and pursuing an irregularly north direction, but never coming in sight of Australia, he discovered, on January 21, 1643, two islands belonging to the Friendly group, to which he gave the names of Middelburg (Eova) and Amsterdam (Tongatabu). After discovering several other islands in the Friendly group and their neighborhood, Tasman steered north and west, reaching the neighborhood of New Britain on March 22. On the 24th he passed Morghen Islands, and, sailing round New Ireland and along the north coast of New Guinea, he cleared the straits between New Guinea and Jilolo, arriving at Batavia on June 15, after a ten months' voyage.[2] The materials for an account of Tasman's important second voyage in 1644 are extremely scanty; they consist of Tasman's own chart and some fragmentary notes by Burgomaster Witsen in his work (1705) on the migrations of the human race (translated in Dalrymple's collection). Further information as to authorities[3] will be found in Mr. R. H. Major's Hakluyt Society volume on *Early Voyages to Australia*, where also will be found the "Instructions" given to Tasman, for his voyage to New Guinea. He is instructed to obtain a thorough knowledge of Staten and Van Diemen's Land, and "whether New Guinea is a continent with the great Zuidland, or separated by channels and islands," and also "whether the new Van Diemen's Land is the same continent with these two great countries or with one of them." In this voyage Tasman had three vessels under his command. His discoveries were confined to the north and northwest coasts of Australia, and his chart gives the soundings for the whole of this line of coast. He discovered the Gulf of Carpentaria, and established the continuity of the northwest coast of the land designated generally "the great known south continent," as far south as about the 22d degree. The fullest details as to maps of the voyage and other authorities will be found in Mr. Major's Hakluyt Society volume referred to above. Tasman rightly ranks as one of the greatest navigators of the 17th century. He died at Batavia in October, 1659.

For personal details, see paper on Tasman by Ch. M. Dozy in *Bijdragen tot de Taal-, Land-, en Volkenkunde van Nederlandsch-Indië*, 5th series, vol. ii. p. 308.

TASMANIA, formerly **VAN DIEMEN'S LAND**, is a compact island, forming a British colony, which lies to the south of Australia, in the Southern Ocean. It has an area of 24,600 square miles (about three-fourths of the size of Ireland), and some fifty islets belong to it. Most of these lie between it and the southern shore of Victoria, in Bass's Strait. It is a land of mountain and flood, with picturesque scenery. The centre is a mass of hills, generally covered with forest, with large lakes nearly 4000 feet above the sea; and this high land is continued to the west and northwest, while southward are other elevations. Ben Lomond in the east rises to a height of 5020 feet; in the northwest are Dry's Bluff (4257 feet) and Quamby (4000); while westward are Cradle (5069), Hugel (4700), Frenchman's Cap (4760), and Bischoff (2500). Wellington, near Hobart, is 4170 feet. Among the rivers flowing northward to Bass's Strait are the Tamar,

Inglis, Cam, Emu, Blyth, Forth, Don, Mersey, Piper, and Ringarooma. The Macquarie, receiving the Elizabeth and Lake, falls into the South Esk, which unites with the North Esk to form the Tamar at Launceston. Westward, falling into the ocean, are the Hellyer, Arthur, and Pieman. The King and Gordon gain Macquarie Harbor; the Davey and Spring, Port Davey. The central and southern districts are drained by the Derwent from Lake St. Clair,—its tributaries being the Nive, Dee, Clyde, Ouse, and Jordan. The Huron falls into D'Entrecasteaux Channel. The chief mountain lakes are the Great Lake (50 miles in circuit), Sorell, St. Clair, Crescent, and Echo. The colony is divided into eighteen counties. The principal towns are Hobart, the capital, on the Derwent, with a population of 21,118 in 1881 (25,044 in 1886), and Launceston (12,752 in 1881; 19,379 in 1886), at the head of the Tamar. The rugged western half of the island has only a few small settlements, while the eastern country is increasing in population on account of the mines.

Climate.—This small colony has a far greater range of climate than can be experienced throughout the Australian continent. The eastern side is dry; the western is very wet. Tin and gold miners are partially arrested in their work during summer from want of water in the northeast. Dense forests and impracticable scrubs result in the west from deposition of a hundred or more inches of rain in the year, while other parts to the east occasionally suffer from drought. Tasmania does not escape the summer visit of an Australian hot wind. Hobart and Launceston, being near the sea, have greater equability of temperature, with rare frosts. The mean temperature of Hobart is 54°, of Waratah in the northwest 44°. Hobart averages 22 inches of rain, less than Melbourne, Sydney, and Brisbane. Inland, in the settled parts, cold is severe in winter, but only for a short period. The wooded northwest shore has no cold and no excessive heat, but plenty of showers. Up in the lake country the climate rather resembles the Highlands of Scotland. On the west and southern coasts the winds are usually strong, and often tempestuous.

Like New Zealand, Tasmania is very healthy. No miasma is retained in its forests. Rheumatism and colds may prevail, but little fever or dysentery occurs. Perhaps no part of the world can show relatively so many aged people. Children generally display the robustness of English village life. As a retreat for Australians, Tasmania in the summer has strong claims. Cool and strengthening airs, magnificent forest solitudes, and secluded fern-tree vales may be enjoyed along with all the comforts of modern civilization.

Geology.—The comparatively recent connection of Tasmania with Victoria is evidenced not less by rocks than by flora and fauna. The granitic islands of Bass's Strait are as so many stepping-stones across, a depression having converted the loftier districts into islands. The want of similarity, however, between the tufted-haired Tasmanians and their Australian neighbors would indicate that the disruption took place before the advent of the younger race on the northern side. While doubts exist as to the presence of rocks older than the Silurian, a Palæozoic floor exists north, east, south, and west, though often thrown up into irregular ranges, sometimes over 5000 feet, by igneous irruptions. Convulsions have distinguished the history of the little island from one end to the other. Not only is granite in all its varieties very prevalent, but there is an immense amount of metamorphism in different directions. Then, at another period, not merely porphyries, but basalts and greenstones, were widespread in their ravages. They consumed or deranged beds of coal, and overflowed enormous tracts. Earthquakes were busy, and tremendous deluges denuded great areas to depths of thousands of feet, leaving mountains of Primary rock, with peaked or plateau summits of basalt or greenstone. There are prismatic walls several hundreds of feet in height, and 4000 feet above the sea-level, as at Mount Wellington, looking down upon "ploughed fields" of greenstone blocks. Still, unlike Victoria, there are not the extinct craters to tell the tale of more modern lava flows. The lake district, up to over 4000 feet, is a tangled mass of granitic and metamorphic rocks. Quartz is so common a feature that the western storm-bound cliffs reflect a white light to passing ships; while mica, talcose, dolerite, and siliceous schists are common over the island. Contorted slate and the tesselated pavement of Tasman's Peninsula are effects of that transmuting period. Granite is strong at eastern and northern points, at western localities, in the interior, and in the straits. Greenstone is exhibited southward in enormous fields, as well as in the western and lake districts, and alternates often with basalt. Silicified trees are seen standing upright in the floor of igneous rock. The Primary rocks have more casts of former life than fossils in ordinary condition. The Hobart clay-slate abounds in *Fenestella* or lace coral, and trilobites occur in limestone. Slate is abundant on the northwest coast, the South Esk, and westward. New Red Sandstone near Hobart is marked by the presence of salt-beds. The Carboniferous formations are not much exhibited on the western half of the island, but are prominent along the Mersey and other northern rivers. The southern fields are torn by igneous invaders. Anthracite forms are conspicuous on Tasman's Peninsula. Inland, on the eastern side, the formations spread from near Hobart northward for scores of miles, and even to a thousand feet in thickness. The Fingal and Ben Lomond northeastern districts are remarkably favored with Carboniferous sandstones and crinoidal limestones, bearing excellent seams, and like strata are noticed in islands off the east coast. Carbonaceous non-coal-bearing beds by the Mersey are 500 feet thick. Tertiary rocks are not extensive, save in the breccia and coarse sandstone south of Launceston, over Norfolk plains, and along some river valleys. Alluvial gold deposits belong mainly to the Pliocene formations,—the ancient Primaries containing the auriferous quartz veins. Greenstone and basalt belong to various periods, the latter being specially apparent in the Tertiary epoch. Travertine, near Hobart and Richmond, is from freshwater action. The Pleistocene development was characterized by overwhelming denuding forces. Raised beaches are noticed along some of the larger rivers, and westerly moraines would imply a greater elevation of the country formerly. Caves and recent beds exhibit marsupial forms analogous to existing ones. Not far from Deloraine are limestone caves, with passages two miles in extent. The density and intricacy of the island scrubs have interfered with the investigation of its geology.

Minerals.—Tasmania has failed to take a very important position as a gold producer. Still, when the crushing of 1300 tons in one mine produced £11,528 [$56,026.08], adventurers may well be hopeful. From Beaconsfield mine, west of the Tamar, gold was obtained to the value of £615,330 [$2,990,503.80] from July, 1878, to January 1, 1887. In 1885 there were five districts under commissioners of mines. Westward, gold is found from Arthur river to Point Hibbs; northwestward, from Blyth river to Cape Grim. In the northeast are Scottsdale, Ringarooma, Mount Victoria, and Waterhouse fields; east, Fingal and St. George river. Arsenic and silver are found with gold in the northeast; and iron, arsenic, copper, and lead with it at Beaconsfield. For 1885 the gold export was 37,498 oz., worth £141,319 [$686,810.34]. Silver occurs at Penguin, Mount Ramsey, and Waratah (Mount Bischoff), combined with lead. Copper is met with at Mount Maurice, etc., but not in paying quantities. Bismuth at Mount Ramsey is rich, but the country is difficult to reach. Antimony, zinc, manganese, copper, plumbago, and galena are known west of the Tamar, where also asbestos in serpentine hills is plentiful. Tin is well distributed in Tasmanian granite. Mount Bischoff, in the scrubby, rocky, damp west, has the richest lodes; other mines are in the northeast and west. In ten years the product came to two and a half million pounds sterling [$12,150,000]. Bischoff district in 1885 gave

2871 tons of ore, much being found in huge blocks. Want of water in the northeast prevents much hydraulic working. Anthracite coal is pretty abundant at Port Arthur. Near Hobart are workings of poor quality. Around Ben Lomond are bituminous seams, but difficult of access. Fingal district has coal equal to that of Newcastle, with a seam of 14 feet, but carriage is difficult. Mersey river coal mines yielded 60,000 tons in the course of over a dozen years. Iron was worked near the Tamar, but did not pay, excess of chromium making it brittle; its steel was very malleable. All varieties of iron ores are known. Hobart freestone is largely exported to other colonies. Tasmanite or dysodile in the Mersey district is an inflammable resinous substance. During 1884 there were raised 41,240 oz. of gold, 5461 tons of tin, and 5334 tons of coal. The total export of gold and tin during the five years 1880 to 1885 was of the value of £2,591,320 [$12,593,815.20]—being £642,230 [$3,121,237.80] more than for the ten years preceding. The export of tin averaged 79,682 cwt.

Agriculture.—The island has not a large area fit for cultivation. A great part is very mountainous; and dense scrubs, with heavy forests, are impediments to the farmer. The west side is too wet, stormy, and sterile for settlement. Almost all the farms lie in the line between Hobart and Launceston and between Launceston and Circular Head. The climate being cooler and moister than in most parts of Australia, the productions are of an English character, hops, barley, and oats being freely raised. Cropping land for many successive years with wheat has lessened the produce of what was fertile country, as little manure had been used. In later times there has been a great improvement in agriculture. For some time Tasmanian growers did well, supplying Australia and New Zealand with flour, potatoes, and fruit; but, as their customers became in their turn producers, the old markets failed in all but apples and stone fruit. Fresh and preserved fruit, with jams, together with excellent hops, continue to afford the islanders a good trade. In 1885–86 there were 417,777 acres in cultivation; in crop, 144,761; in grasses, 181,203. Wheat occupied 30,266 acres, barley 6833, oats 29,247, pease 7147, potatoes 11,073, hay 41,693, turnips 3680, and gardens and orchards 8198.

So large a part of the island is covered with thicket, rock, and marsh that it appears less pastoral than eastern Australia. The total number of sheep in 1886 amounted to 1,648,627, the horses to 28,610, and the cattle to 138,642. Of 16,778,000 acres only 4,403,888 have been sold or granted.

Flora.—This differs but little from that of southeastern Australia, with which it was formerly connected. Over a thousand species are represented. The eucalypts are gums, stringy bark, box, peppermint, ironwood, etc. The celebrated blue gum (*Eucalyptus Globulus*), so eagerly sought for pestilential places in southern Europe, Africa, and America, flourishes best in the southern districts of the island. For shipbuilding purposes the timber, which grows to a large size, is much prized. Acacias are abundant, and manna trees are very productive. Sassafras (*Atherosperma moschata*) is a tall and handsome tree. Pines are numerous. The Huon pine (*Dacrydium cupressinum*), whose satin-like wood is so sought after, flourishes in Huon and Gordon river districts. The celery pine is a *Phyllocladus*, and the pencil cedar an *Athrotaxis.* The pepper tree is *Tasmania fragrans.* The *Myrtaceæ* are noble trees. The lakes cider tree is *Eucalyptus resinifera,* whose treacle-like sap was formerly made into a drink by bushmen. Xanthorrhœas or grass trees throw up a flowering spike. The charming red flowers of the Tasmanian tulip tree (*Telopea*) are seen from a great distance on the sides of mountains. The so-called rice plant, with rice-like grains on a stalk, is the grass *Richea.* Of *Boronia, Epacris,* and *Orchis* there are numerous species. The *Blandfordia,* a Liliaceous plant, has a head of brilliant crimson flowers. The *Casuarina, Exocarpus, Banksia,* and tree fern resemble those of Australia. Tasmanian evergreen forests are very aromatic. At one time the island had an extensive timber trade with Sydney, Melbourne, and Adelaide, and it still exports £50,000 [$243,000] to £80,000 [$388,800] worth annually of planks, shingles, paling, etc.

Fauna.—Animal life in Tasmania is similar to that in Australia. The dingo or dog of the latter is wanting; and the Tasmanian devil and tiger, or wolf, are peculiar to the island. The Marsupials include the *Macropus* or kangaroo, *Didelphys* or opossum, *Petaurus* or flying phalanger,[1] *Perameles* or bandicoot, *Hypsiprymnus* or kangaroo rat, *Phascolomys* or wombat; while of *Monotremata* there are the *Echidna* or porcupine anteater and the duck-billed platypus. The marsupial tiger or Tasmanian wolf (*Thylacinus cynocephalus*), 5 feet long, is yellowish brown, with several stripes across the back, having short stiff hair and very short legs (see vol. xv. p. 382–3). Very few of these nocturnal carnivores are now alive to trouble flocks. The tiger cat of the colonists, with weasel legs, white spots, and nocturnal habits, is a large species of the untameable native cats. The devil (*Dasyurus* or *Sarcophilus ursinus*) is black, with white bands on neck and haunches. The covering of this savage but cowardly little night-prowler is a sort of short hair, not fur. The tail is thick, and the bull-dog mouth is formidable. Among the birds of the island are the eagle, hawk, petrel, owl, finch, peewit, diamond bird, fire-tail, robin, emu-wren, crow, swallow, magpie, blackcap, goatsucker, quail, ground dove, jay, parrot, lark, mountain thrush, cuckoo, wattlebird, whistling duck, honeybird, Cape Barren goose, penguin duck, waterhen, snipe, albatross, and laughing jackass. Snakes are pretty plentiful in scrubs; the lizards are harmless. Insects, though similar to Australian ones, are far less troublesome; many are to be admired for their great beauty.

Fisheries.—In the early years of occupation the island was the resort of whalers from the United Kingdom, the United States, and France. Both sperm and black oil, with whalebone, were important articles of export till the retreat of the whales to other seas. Sealing was carried on successfully for many years in Bass's Strait, until the seals were utterly destroyed. There has recently been a revival of whaling, the product of the island fishery for 1885 being £12,600 [$61,236]. The bays contain some excellent fish, much esteemed in the neighboring colonies, particularly the trumpeter, found on the southern side of the island. Of nearly 200 sorts of fishes a third can be considered good for food. The outer fisheries extend to 16 miles from shore, being from 20 to 80 fathoms deep. The species include the trumpeter (*Latris,* found up to 60 ℔ weight), the "salmon" of the old settlers (*Arripis*), the flathead (*Platycephalus*), trevally (*Neptonemus*), garfish (*Hemirhamphus*), barracouta and kingfish (both *Thyrsites*). There are thirteen sorts of perch, and five of bream. The anchovy is migatory. English mackerel have been seen off the east coast; and some of the herrings are much like the English. Rock cod and bull-kelp cod are favorites. Mud oysters are nearly worked out; artificial oyster-beds are being formed. English trout (*Salmo fario*) are more certainly found than the true salmon (*Salmo salar*); the last are doubtful, though numbers have been raised in hatcheries on the Derwent. Among freshwater fish are a so-called freshwater herring (*Prototroctes*), various kinds of what the old settlers called trout (*Galaxias*), blackfish (*Gadopsis*), and fine perch.

Commerce.—Soon after the colony was founded there was a great trade in whale oil, as well as in the oil and skins of seals. When this declined, merchants did well in the exportation of breadstuffs, fruits, and vegetables to the neighboring and more recently established colonies, not less than to New South Wales. Timber was also freely sent to places less favored with forests or too busy with other employments. When the trade with England in oil fell off, the export in wool and then of metals succeeded. Tasmania has now an active commerce with Victoria, but has a competitor rather than a customer in New Zealand. The shipping during 1885 was 342,745 tons inward, 335,061 outward. The imports for that year came to £1,757,486 [$8,541,381.96]; the exports to £1,313,693 [$6,384,547.98]. Of the exports, £1,299,011 [$6,313,193.46] were of Tasmanian products and manufactures,—including wool, £260,480 [$1,265,932.80]; tin, £357,587 [$1,737,872.82]; gold, £141,319 [$686,810.34]; fruit, £105,363 [$512,064.18]. The banks of the colony at the end of 1885 showed assets £3,754,226 [$18,245,538.36], and liabilities, £3,814,631 [$18,539,106.66]. The savings banks early in 1886 declared £455,774 [$2,215,061.64] to the credit of depositors. Attempts have been recently made to draw Tasmania into closer commercial and fiscal relations with Victoria.

Manufactures.—Numerous industries are practiced, though not to the extent of exportation, excepting from the working of 28 tanneries, 62 sawmills, 13 breweries, 7 manufactories of jam, and a rising wool factory.

Roads and Railways.—No colony, for its area, was ever so favored with excellent roads as Tasmania has been. There are now about 5000 miles of good roads. The principal line of railway is that from Hobart to Launceston. Altogether, 260 miles[2] of railway were open in 1887.

Post-Office.—In early years letters were carried by runners on foot across the island. In 1885 there were 246 post-offices, and the telegraph had 1579 miles[2] of wire. A submarine line connects Tasmania with Victoria.

Administration.—The governor is appointed by the British crown. The legislative council has eighteen members, and the assembly thirty-six. The revenue for 1885–86 was £571,396 [$2,776,984.56], the expenditure £585,766 [$2,846,822.76]. The public debt,[1] contracted for public works, amounts to three and a third millions [$16,200,000]. The customs provided £276,100 [$1,341,846]. The official machinery is as extensive as for a colony with seven or eight times the population.

---

[1] [The *Didelphys* is American, but phalangers are called opossums by Australasian colonists. The *Petaurus* does not occur in Tasmania, but the Brown phalanger or *Ph. fuliginosa* does. See vol. xviii. p. 742.—AM. ED.]

[2] [For year 1886–7 there were 251 post stations, 2352 miles of telegraph wire, revenues of £568,924 [$2,764,970.64], expenditure £584,756 [$2,841,914.16], public debt £4,026,720 [$19,569,859], railways 303 miles, fruit exports over $722,000.—AM. ED.]

Education.—At first the state made grants in aid to schools established by private persons and religious denominations, but ultimately, as in Victoria and New Zealand, education was made secular and compulsory, religious teaching being out of school hours, or dependent on Sunday schools, which are to be found all over the island. There are 204 public schools, maintained out of a fund of £32,793 [$159,573.98]. In eight grammar and collegiate schools a higher standard of instruction is reached. The degree of Associate of Arts is conferred on deserving scholars in the state schools; and exhibitions (up to £200 [$962] a year for four years) enable pupils to study at the higher schools or colonial or European universities. No state grant is now made for the support of any religious denomination.

Population.—The whites have entirely displaced the blacks. Outrages and cruelties led to conflicts; and now the last individual of the tribes has passed away. There are, however, some half-castes on islands in the Straits. The colonists in Tasmania are more concentrated than in other settlements. In 1818 there were 2320 men, 432 women, and only 489 children. At the census of 1881 the population numbered 115,705 (61,162 males, 54,543 females); in 1886 it was estimated at 133,791. The births in 1886 averaged 34.6 per thousand, the deaths 15.2.

History.—The Dutch navigator TASMAN (*q.v.*) sighted the island November 24, 1642, and named it Van Diemen's Land, after the Dutch governor of Java. He took possession at Frederick Henry Bay in the name of the stadtholder of Holland, and then passed on to the discovery of New Zealand. The French Captain Marion in 1772 came to blows with the natives. Captain Cook was at Adventure Bay, to the south, in 1777. His companion, Captain Furneaux, had entered the bay four years previously, assuring Cook that Van Diemen's Land was joined to New Holland. Admiral Bruni d'Entrecasteaux, with the naturalist La Billardière, entered the Derwent, calling it North River, in 1792. Two years after, Captain Hayes named it Derwent. Mr. Bass and Lieutenant Flinders passed through Bass's Strait, and first sailed round the island, in 1798. The high terms in which they spoke of Sullivan's cove, at the mouth of the Derwent, afterwards led to the settlement of Hobart there. The French discovery ships, "Géographe" and "Naturaliste," under Commodore Baudin were off the coast in 1801–2. The island was settled from Sydney. A small party was sent to the Derwent, under Lieutenant Bowen, in 1803, and another to Port Dalrymple next year under Colonel Paterson, who was removed to Launceston in 1806. Captain Collins, who had been sent with a large number of convicts from England to form a penal colony in Port Phillip, thought proper to remove thence after three months, and establish himself at Hobart Town, February, 1804. The early days were trying, from want of supplies and of good government; and conflicts arose with the natives, which led to the celebrated Black War. In 1830 nearly all the settlers, with 4000 soldiers and armed constables, attempted to drive the aborigines into a peninsula, but caught only one lad. Mr. George Robinson afterwards succeeded in inducing the few hunted ones to surrender and be taken to Flinders Island. Deaths rapidly followed. The last man died in 1862, the last female in 1872. Bushranging was common for years in this scrubby land. The colony was subject to New South Wales till 1825, when independence was declared. On free settlers being permitted to go to Van Diemen's Land, they endeavored to get freedom of the press, trial by jury, and a popular form of rule. After long struggles, the liberties they sought for were gradually granted. A responsible government was the last boon received. Oppressed by the number of convicts thrown into the country, the free inhabitants petitioned again and again for the cessation of transportation, which was eventually allowed. Among the governors was Sir John Franklin, of polar celebrity. The first newspaper, *The Derwent Star*, came out in 1810. Literature advanced from that humble beginning. At first the Government entirely supported schools and churches, and for many years state aid was afforded to the Church of England, Presbyterian, Wesleyan, and Roman Catholic churches, but this aid is now withdrawn. The island proving too small for a large population, numbers swarmed off to the neighboring settlements, and Port Phillip, now Victoria, received its first inhabitants from Tasmania. Though not so prosperous as Victoria, the little island enjoys an amount of ease and comfort which few, if any, settlements elsewhere have been known to experience. (J. BO.)

TASSIE, JAMES (1735–1799), gem-engraver and modeller, was born of humble parentage at Pollokshaws, near Glasgow, in 1735. During his earlier years he worked as a stone-mason, but, having visited Glasgow on a fair-holiday, and seen the collection of paintings brought together in that city by Robert and Andrew Foulis, the celebrated printers, he was seized with an irresistible desire to become an artist. He removed to Glasgow, attended the academy which had been established there by the brothers Foulis, and, applying himself to drawing with indomitable perseverance, seconded by great natural aptitude, he eventually became one of the most distinguished pupils of the school. When his training was completed he visited Dublin in search of commissions, and there became acquainted with Dr. Quin, who had been experimenting, as an amateur, in imitating antique engraved gems in colored pastes. He engaged Tassie as an assistant, and together they perfected the discovery of a vitreous paste composition, styled "enamel," a substance admirably adapted, by its hardness and beauty of texture, for the formation of gems and medallions. Dr. Quinn encouraged his assistant to try his fortune in London, and thither he repaired in 1766. At first he had a hard struggle to make his way, for he was modest and diffident in the extreme, and without influential introductions to amateurs and collectors. But he worked on steadily with the greatest care and accuracy, scrupulously destroying all impressions of his gems which were in the slightest degree inferior or defective. Gradually the beauty and artistic character of his productions came to be known. He received a commission from the empress of Russia for a collection of about 15,000 examples; all the richest cabinets in Europe were thrown open to him for purposes of study and reproduction; and his copies were frequently sold by fraudulent dealers as the original gems. He exhibited in the Royal Academy from 1769 to 1791. In 1775 he published the first catalogue of his works, a thin pamphlet detailing 2856 items. This was followed in 1791 by a large catalogue, in two volumes quarto, with illustrations etched by David Allan, and descriptive text in English and French by Rudolph Eric Raspe, F.S.A., enumerating nearly 16,000 pieces. Materials exist in MS., in the possession of a descendant of Tassie's, for a list of more than 3000 further items.

In addition to his impressions from antique gems, Tassie executed many large profile medallion portraits of his contemporaries, and these form the most original and definitely artistic class of his works. They were modelled in wax from the life or from drawings done from the life, and —when this was impossible— from other authentic sources. They were then cast in white enamel paste, the whole medallion being sometimes executed in this material; while in other cases the head only appears in enamel, relieved against a background of ground glass tinted of a subdued color by paper placed behind. His first large enamel portrait was that of John Dolbon, son of Sir William Dolbon, Bart., modelled in 1793 or 1794; and the series possesses great historic interest, as well as artistic value, including as it does portraits of Adam Smith, Sir Henry Raeburn, Drs. James Beattie, Blair, Black, and Cullen, and many other celebrated men of the latter half of the 18th century.

At the time of his death, in 1799, the collection of Tassie's works numbered about 20,000 pieces. (J. M. G.)

TASSIE, WILLIAM (1777–1860), gem-engraver and modeller, nephew of the above, was born in London on the 4th of December, 1777. He succeeded to the business of his uncle, to whose collection of casts and medallions he added largely. His portrait of Pitt, in particular, was very popular, and circulated widely. When the Shakespeare Gallery, formed by Alderman Boydell, was disposed of by lottery in 1805, William Tassie was the winner of the prize, and in the same year he sold the pictures by auction for a sum of over £6000 [$29,160]. He died at Kensington on the 26th of October, 1860, and bequeathed to the Board of Manufactures, Edinburgh, an extensive and valuable collection of casts and medallions by his uncle and himself, along with portraits of James Tassie and his wife by David Allan, and a series of water-color studies by George Sanders from pictures of the Dutch and Flemish schools. (J. M. G.)

---

[1] See foot-note 2, page 80.

TASSO, TORQUATO (1544–1595), who ranks with Dante, Petrarch, and Ariosto among the first four poets of Italy, was the son of Bernardo Tasso, a nobleman of Bergamo, and his wife Porzia de' Rossi. He was born at Sorrento in 1544. His father had for many years been secretary in the service of the prince of Salerno, and his mother was closely connected with the most illustrious Neapolitan families. The prince of Salerno came into collision with the Spanish Government of Naples, was outlawed, and was deprived of his hereditary fiefs. In this disaster of his patron Tasso's father shared. He was proclaimed a rebel to the state, together with his son Torquato, and his patrimony was sequestered. These things happened during the boy's childhood. In 1552 he was living with his mother and his only sister Cornelia at Naples, pursuing his education under the Jesuits, who had recently opened a school there. The precocity of intellect and the religious fervor of the boy attracted general admiration. At the age of eight he was already famous. Soon after this date he joined his father, who then resided in great indigence, an exile and without occupation, in Rome. News reached them in 1556 that Porzia Tasso had died suddenly and mysteriously at Naples. Her husband was firmly convinced that she had been poisoned by her brother with the object of getting control over her property. As it subsequently happened Porzia's estate never descended to her son; and the daughter Cornelia married below her birth, at the instigation of her maternal relatives. Tasso's father was a poet by predilection and a professional courtier of some distinction. In those days an Italian gentleman of modest fortunes had no congenial sphere of society or occupations outside the courts of petty ecclesiastical and secular princes. When, therefore, an opening at the court of Urbino offered in 1557, Bernardo Tasso gladly accepted it. The young Torquato, a handsome and brilliant lad, became the companion in sports and studies of Francesco Maria della Rovere, heir to the dukedom of Urbino. The fate which condemned him for life to be a poet and a courtier like his father was sealed by this early entrance into princely palaces. At Urbino a society of cultivated men pursued the æsthetical and literary studies which were then in vogue. Bernardo Tasso read cantos of his *Amadigi* to the duchess and her ladies, or discussed the merits of Homer and Virgil, Trissino and Ariosto, with the duke's librarians and secretaries. Torquato grew up in an atmosphere of refined luxury and somewhat pedantic criticism, both of which gave a permanent tone to his character. At Venice, whither his father went to superintend the printing of the *Amadigi*, these influences continued. He found himself the pet and prodigy of a distinguished literary circle. But Bernardo had suffered in his own career so seriously from addiction to the Muses and a prince that he now determined on a lucrative profession for his son. Torquato was sent to study law at Padua. Instead of applying himself to law, the young man bestowed all his attention upon philosophy and poetry. Before the end of 1562 he had produced a narrative poem called *Rinaldo*, which was meant to combine the regularity of the Virgilian with the attractions of the romantic epic. In the attainment of this object, and in all the minor qualities of style and handling, *Rinaldo* showed such marked originality that its author was proclaimed the most promising poet of his time. The flattered father allowed it to be printed; and, after a short period of study at Bologna, he consented to his son's entering the service of Cardinal Luigi d'Este. In 1565, then, Torquato for the first time set foot in that castle at Ferrara which was destined for him to be the scene of so many glories and such cruel sufferings. After the publication of *Rinaldo*, he had expressed his views upon the epic in some *Discourses on the Art of Poetry*, which committed him to a distinct theory and gained for him the additional celebrity of a philosophical critic. The age was nothing if not critical; but it may be esteemed a misfortune for the future author of the *Gerusalemme* that he should have started with pronounced opinions upon art. Essentially a poet of impulse and instinct, he was hampered in production by his own rules.

The five years between 1565 and 1570 seem to have been the happiest of Tasso's life, although his father's death in 1569 caused his affectionate nature profound pain. Young, handsome, accomplished in all the exercises of a well-bred gentleman, accustomed to the society of the great and learned, illustrious by his published works in verse and prose, he became the idol of the most brilliant court in Italy. The princesses Lucrezia and Leonora d'Este, both unmarried, both his seniors by about ten years, took him under their protection. He was admitted to their familiarity, and there is some reason to think that neither of them was indifferent to him personally. Of the celebrated story of his love for Leonora this is not the place to speak. It is enough at present to observe that he owed much to the constant kindness of both sisters. In 1570 he travelled to Paris with the cardinal. Frankness of speech and a certain habitual want of tact caused a disagreement with his worldly patron. He left France next year, and took service under Duke Alfonso II., of Ferrara. The most important events in Tasso's biography during the following four years are the publication of the *Aminta* in 1573 and the completion of the *Gerusalemme Liberata* in 1574. The *Aminta* is a pastoral drama of very simple plot, but of exquisite lyrical charm. It appeared at the critical moment when modern music, under Palestrina's impulse, was becoming the main art of Italy. The honeyed melodies and sensuous melancholy of *Aminta* exactly suited and interpreted the spirit of its age. We may regard it as the most decisively important of Tasso's compositions, for its influence, in opera and cantata, was felt through two successive centuries. The *Gerusalemme Liberata* occupies a larger space in the history of European literature, and is a more considerable work. Yet the commanding qualities of this epic poem, those which revealed Tasso's individuality, and which made it immediately pass into the rank of classics, beloved by the people no less than by persons of culture, are akin to the lyrical graces of *Aminta*. It was finished in Tasso's thirty-first year; and when the MS. lay before him the best part of his life was over, his best work had been already accomplished. Troubles immediately began to gather round him. Instead of having the courage to obey his own instinct, and to publish the *Gerusalemme* as he had conceived it, he yielded to the critical scrupulosity which formed a secondary feature of his character. The poem was sent in manuscript to several literary men of eminence, Tasso expressing his willingness to hear their strictures and to adopt their suggestions unless he could convert them to his own views. The result was that each of these candid friends, while expressing in general high admiration for the epic, took some exception to its plot, its title, its moral tone, its episodes, or its diction, in detail. One wished it to be more regularly classical; another wanted more romance. One hinted that the Inquisition would not tolerate its supernatural machinery; another demanded the excision of its most charming passages—the loves of Armida, Clorinda and Erminia.

Tasso had to defend himself against all these ineptitudes and pedantries, and to accomodate his practice to the theories he had rashly expressed. As in the *Rinaldo*, so also in the *Jerusalem Delivered*, he aimed at ennobling the Italian epic style by preserving strict unity of plot and heightening poetic diction. He chose Virgil for his model, took the first crusade for subject, infused the fervor of religion into his conception of the hero Godfrey. But his own natural bias was for romance. In spite of the poet's ingenuity and industry the stately main theme evinced less spontaneity of genius than the romantic episodes with which, as also in *Rinaldo*, he adorned it. Godfrey, a mixture of pious Æneas and Tridentine Catholicism, is not the real hero of the *Gerusalemme*. Fiery and passionate Rinaldo, Ruggiero, melancholy impulsive Tancredi, and the chivalrous Saracens with whom they clash in love and war, divide our interest and divert it from Goffredo. On Armida, beautiful witch, sent forth by the infernal senate to sow discord in the Christian camp, turns the action of the epic. She is converted to the true faith by her adoration for a crusading knight, and quits the scene with a phrase of the Virgin Mary on her lips. Brave Clorinda, donning armor like Marfisa, fighting in duel with her devoted lover, and receiving baptism from his hands in her pathetic death; Erminia seeking refuge in the shepherd's hut, —these lovely pagan women, so touching in their sorrows, so romantic in their adventures, so tender in their emotions, rivet our attention, while we skip the battles, religious ceremonies, conclaves and stratagems of the campaign. The truth is that Tasso's great invention as an artist was the poetry of sentiment. Sentiment, not sentimentality, gives value to what is immortal in the *Gerusalemme*. It was a new thing in the 16th century, something concordant with a growing feeling for woman and with the ascendant art of music. This sentiment, refined, noble, natural, steeped in melancholy, exquisitely graceful, pathetically touching, breathes throughout the episodes of the *Gerusalemme*, finds metrical expression in the languishing cadence of its mellifluous verse, and sustains the ideal life of those seductive heroines whose names were familiar as household words to all Europe in the 17th and 18th centuries.

Tasso's self-chosen critics were not men to admit what the public has since accepted as incontrovertible. They vaguely felt that a great and beautiful romantic poem was embedded in a dull and not very correct epic. In their uneasiness they suggested every course but the right one, which was to publish the *Gerusalemme* without further dispute. Tasso, already overworked by his precocious studies, by exciting court-life and exhausting literary industry, now grew almost mad with worry. His health began to fail him. He complained of headache, suffered from malarious fevers, and wished to leave Ferrara. The *Gerusalemme* was laid in manuscript upon a shelf. He opened negotiations with the court of Florence for an exchange of service. This irritated the duke of Ferrara. Alfonso hated nothing more than his courtiers leaving him for a rival duchy. He thought, moreover, that, if Tasso were allowed to go, the Medici would get the coveted dedication of that already famous epic. Therefore he bore with the poet's humors, and so contrived that the latter should have no excuse for quitting Ferrara. Meanwhile, through the years 1575, 1576, 1577, Tasso's health grew worse. Jealousy inspired the courtiers to calumniate and insult him. His irritable and suspicious temper, vain and sensitive to slights, rendered him only too easy a prey to their malevolence. He became the subject of delusions,—thought that his servants betrayed his confidence, fancied he had been denounced to the Inquisition, expected daily to be poisoned. In the autumn of 1576 he quarrelled with a Ferrarese gentleman, Maddalo, who had talked too freely about some love affair; in the summer of 1577 he drew his knife upon a servant in the presence of Lucrezia d'Este, duchess of Urbino. For this excess he was arrested; but the duke released him, and took him for change of air to his country seat of Belriguardo. What happened there is not known. Some biographers have surmised that a compromising *liaison* with Leonora d'Este came to light, and that Tasso agreed to feign madness in order to cover her honor. But of this there is no proof. It is only certain that from Belriguardo he returned to a Franciscan convent at Ferrara, for the express purpose of attending to his health. There the dread of being murdered by the duke took firm hold on his mind. He escaped at the end of July, disguised himself as a peasant, and went on foot to his sister at Sorrento.

The truth seems to be that Tasso, after the beginning of 1575, became the victim of a mental malady, which, without amounting to actual insanity, rendered him fantastical and insupportable, a misery to himself and a cause of anxiety to his patrons. There is no evidence whatsoever that this state of things was due to an overwhelming passion for Leonora. The duke, instead of acting like a tyrant, showed considerable forbearance. He was a rigid and not sympathetic man, as egotistical as a princeling of that age was wont to be. But to Tasso he was never cruel,—hard and unintelligent perhaps, but far from being that monster of ferocity which has been painted. The subsequent history of his connection with the poet, over which we may pass rapidly, will corroborate this view. While at Sorrento, Tasso hankered after Ferrara. The court-made man could not breathe freely outside its charmed circle. He wrote humbly requesting to be taken back. Alfonso consented, provided Tasso would agree to undergo a medical course of treatment for his melancholy. When he returned, which he did with alacrity under those conditions, he was well received by the ducal family. All might have gone well if his old maladies had not revived. Scene followed scene of irritability, moodiness, suspicion, wounded vanity, and violent outbursts. In the summer of 1578 he ran away again; travelled through Mantua, Padua, Venice, Urbino, Lombardy. In September he reached the gates of Turin on foot, and was courteously entertained by the duke of Savoy. Wherever he went, "wandering like the world's rejected guest," he met with the honor due to his illustrious name. Great folk opened their houses to him gladly, partly in compassion, partly in admiration of his genius. But he soon wearied of their society, and wore their kindness out by his querulous peevishness. It seemed, moreover, that life was intolerable to him outside Ferrara. Accordingly he once more opened negotiations with the duke; and in February, 1579, he again set foot in the castle. Alfonso was about to contract his third marriage, this time with a princess of the house of Mantua. He had no children; and, unless he got an heir, there was a probability that his state would fall, as it did subsequently, to the Holy See. The nuptial festivals, on the eve of which Tasso arrived, were not therefore the occasion of great rejoicing to the elderly bridegroom. As a forlorn hope he had to wed a third wife; but his heart was not engaged and his expectations were far from sanguine. Tasso, preoccupied as always with his own sorrows and his own sense of dignity, made no allowance for the troubles of his master. Rooms below his rank, he thought, had been assigned him. The princesses did not want to see him. The duke was engaged. Without exercising common patience, or giving his old friends the benefit of a doubt, he broke into terms of open abuse, behaved like a lunatic, and was sent off without ceremony to the madhouse of St. Anna. This happened in March, 1579; and there he remained until July, 1586. Duke Alfonso's long-sufferance at last had given way. He firmly believed that Tasso was insane, and he felt that if he were so St. Anna was the safest place for him. Tasso had put himself in the wrong by his intemperate conduct, but far more by that incomprehensible yearning after the Ferrarese court which made him return to it again and yet again. It would be pleasant to assume that an unconquerable love for Leonora led him back. Unfortunately, there is no proof of this. His relations to her sister Lucrezia were not less intimate and affectionate than to Leonora. The lyrics he addressed to numerous ladies are not less respectful and less passionate than those which bear her name. Had he compromised her honor, the duke would certainly have had him murdered. Custom demanded this retaliation, and society approved of it. If therefore Tasso really cherished a secret lifelong devotion to Leonora, it remains buried in impenetrable mystery. He did certainly not behave like a loyal lover, for both when he returned to Ferrara in 1578 and in 1579 he showed no capacity for curbing his peevish humors in the hope of access to her society.

It was no doubt very irksome for a man of Tasso's pleasure-loving, restless, and self-conscious spirit to be kept for more than seven years in confinement. Yet we must weigh the facts of the case rather than the fancies which have been indulged regarding them. After the first few months of his incarceration he obtained spacious apartments, received the visits of friends, went abroad attended by responsible persons of his acquaintance, and corresponded freely with whomsoever he chose to address. The letters written from St. Anna to the princes and cities of Italy, to warm well-wishers, and to men of the highest reputation in the world of art and learning, form our most valuable source of information, not only on his then condition, but also on his temperament at large. It is singular that he spoke always respectfully, even affectionately, of the duke. Some critics have attempted to make it appear that he was hypocritically kissing the hand which had chastised him, with the view of being released from prison. But no one who has impartially considered the whole tone and tenor of his epistles will adopt this opinion. What emerges clearly from them is that he labored under a serious mental disease, and that he was conscious of it. He complains that his disorder at times amounted to frenzy, after which his memory was weakened and his intellectual faculties enfeebled. He saw visions and heard phantom voices. Puck-like spirits made away with his books and papers. The old dread of poison, the old terror of the Inquisition, returned with greater violence. His bodily condition grew gradually worse; and, though he does not seem to have suffered from acute attacks of illness, the intellectual and physical constitution of the man was out of gear. Meanwhile he occupied his uneasy leisure with copious compositions. The mass of his prose dialogues on philosophical and ethical themes, which is very considerable, we owe to the years of imprisonment in St. Anna. Except for occasional odes or sonnets—some written at request and only rhetorically interesting, a few inspired by his keen sense of suffering and therefore poignant—he neglected poetry. But everything which fell from his pen during this period was carefully preserved by the Italians, who, while they regarded him as a lunatic, somewhat illogically scrambled for the very offscourings of his wit. Nor can it be said that society was wrong. Tasso had proved himself an impracticable human being; but he remained a man of genius, the most interesting personality in Italy. Long ago his papers had been sequestered. Now, in the year 1580, he heard that part of the *Gerusalemme* was being published without his permission and without his corrections. Next year the whole poem was given to the world, and in the following six months seven editions issued from the press. The prisoner of St. Anna had no control over his editors; and from the masterpiece which placed him on the level of Petrarch and Ariosto he never derived one penny of pecuniary profit. A rival poet at the court of Ferrara undertook to revise and re-edit his lyrics in 1582. This was Battista Guarini; and Tasso, in his cell, had to allow odes and sonnets, poems of personal feeling, occasional pieces of compliment, to be collected and emended, without lifting a voice in the matter. A few years later, in 1585, two Florentine pedants of the Della Crusca academy declared war against the *Gerusalemme.* They loaded it with insults, which seem to those who read their pamphlets now mere parodies of criticism. Yet Tasso felt bound to reply; and he did so with a moderation and urbanity which prove him to have been not only in full possession of his reasoning faculties, but a gentleman of noble manners also. Certainly the history of Tasso's incarceration at St. Anna is one to make us pause and wonder. The man, like Hamlet, was distraught through ill-accommodation to his circumstances and his age; brain-sick he was undoubtedly; and this is the duke of Ferrara's justification for the treatment he endured. In the prison he bore himself pathetically, peevishly, but never ignobly. He showed a singular indifference to the fate of his great poem, a rare magnanimity in dealing with its detractors. His own personal distress, that terrible *malaise* of imperfect insanity, absorbed him. What remained over, untouched by the malady, unoppressed by his consciousness thereof, displayed a sweet and gravely-toned humanity. The oddest thing about his life in prison is that he was always trying to place his two nephews, the sons of his sister Cornelia, in court-service. One of them he attached to the duke of Mantua, the other to the duke of Parma. After all his father's and his own lessons of life, he had not learned that the court was to be shunned like Circe by an honest man. In estimating duke Alfonso's share of blame, this wilful idealization of the court by Tasso must be taken into account. That man is not a tyrant's victim who moves heaven and earth to place his sister's sons with tyrants.

In 1586 Tasso left St. Anna at the solicitation of Vincenzo Gonzaga, prince of Mantua. He followed his young deliverer to the city by the Mincio, basked awhile in liberty and courtly pleasures, enjoyed a splendid reception from his paternal town of Bergamo, and produced a meritorious tragedy called *Torrismondo.* But only a few months had passed when he grew discontented. Vincenzo Gonzaga, succeeding to his father's dukedom of Mantua, had scanty leisure to bestow upon the poet. Tasso felt neglected. In the autumn of 1587 we find him journeying through Bologna and Loreto to Rome, and taking up his quarters there with an old friend, Scipione Gonzaga, now patriarch of Jerusalem. Next year he wandered off to Naples, where he wrote a dull poem on *Monte Oliveto.* In 1589 he returned to Rome, and took up his quarters again with the patriarch of Jerusalem. The servants found him insufferable, and turned him out of doors. He fell ill, and went to a hospital. The patriarch in 1590 again received him. But Tasso's restless spirit drove him forth to Florence. The Florentines said, "Actum est de eo." Rome once more, then Mantua, then Florence, then Rome, then Naples, then Rome, then Naples—such is the weary record of the years 1590-94. We have to study a veritable Odyssey of malady, indigence, and misfortune. To Tasso everything came amiss. He had the palaces of princes, cardinals, patriarchs, nay popes, always open to him. Yet he could rest in none. To rest would have been so easy, had he possessed the temperament of Berni or of Horace. But he was out of joint with the world. No sensuous comforts, no tranquillity of living, soothed his vexed soul. Gradually, in spite of all veneration for the *sacer vates*, he made himself the laughing-stock and bore of Italy.

His health grew ever feebler and his genius dimmer. In 1592 he gave to the public a revised version of the *Gerusalemme.* It was called the *Gerusalemme Conquistata.* All that made the poem of his early manhood charming he rigidly erased. The versification was degraded; the heavier elements of the plot underwent a dull rhetorical development. During the same year a prosaic composition in Italian blank verse, called *Le Sette Giornate*, saw the light. Nobody reads it now. We only mention it as one of Tasso's dotages—a dreary amplification of the first chapter of Genesis.

It is singular that just in these years, when mental disorder, physical weakness, and decay of inspiration seemed dooming Tasso to oblivion, his old age was cheered with brighter rays of hope. Clement VIII. ascended the papal chair in 1592. He and his nephew, Cardinal Aldobrandini of St. Giorgio, determined to befriend our poet. In 1594 they invited him to Rome. There he was to assume the crown of bays, as Petrarch had assumed it, on the Capitol. Lean and worn out with sickness, ready to totter into the tomb, where rest might possibly be found, Tasso reached Rome in November. The ceremony of his coronation was deferred because Cardinal Aldobrandini had fallen ill. But the pope assigned him a pension; and, under the pressure of pontifical remonstrance, Prince Avellino, who held Tasso's maternal estate, agreed to discharge a portion of his claims by payment of a yearly rent-charge. At no time since Tasso left St. Anna had the heavens apparently so smiled upon him. Capitolian honors and money were now at his disposal. Yet this good fortune came too late. It seemed as though fate had decided that this man, in all his weakness of character and pathetic grace of genius, should win the stern fame of martyrdom. Both laurel wreath and wealth must be withdrawn from him. Before the crown was worn or the pensions paid he ascended to the convent of St. Onofrio, on a stormy 1st day of April, in 1595. Seeing a cardinal's coach toil up the steep Trasteverine Hill, those good monks came to the door to greet it. From the carriage stepped Tasso, the Odysseus of many wanderings and miseries, the singer of sweetest strains still vocal, and told the prior he was come to die with him.

In St. Onofrio he died, on the 25th of April of that year 1595. He was just past fifty-one; and the last twenty years of his existence had been practically and artistically ineffectual. At the age of thirty-one the *Gerusalemme*, as we have it, was accomplished. The world too was already ringing with the music of *Aminta*. More than this Tasso had not to give to literature. But those succeeding years of derangement, exile, imprisonment, poverty, and hope deferred endear the man to us. Elegiac and querulous as he must always appear, we yet love Tasso better because he suffered through nearly a quarter of a century of slow decline and unexplained misfortune.

Taken altogether, the best complete edition of Tasso's writings is that of Rosini (Pisa), in 33 vols. The prose works (in 2 vols., Florence, Le Monnier, 1875) and the letters (in 5 vols., same publishers, 1853) have been admirably edited by Cesare Guasti. This edition of Tasso's *Letters* forms by far the most valuable source for his biography. No student can, however, omit to use the romantic memoir attributed to Tasso's friend, Marchese Manso (printed in Rosini's edition of Tasso's works above cited), and the important *Vita di Torquato Tasso* by Serassi (Bergamo, 1790). To give anything like a complete account of more recent critical and biographical Tasso literature is impossible within the limits of this article.[1] (J. A. S.)

TASSONI, **Alessandro**, Italian poet, was a native of Modena, where he was born in 1565, and where he died in 1635. From 1599 till 1608 he was secretary to Cardinal Ascanio Colonna, and in this capacity saw some diplomatic service; he was afterwards employed for some time in similar occupations by Charles Emmanuel, duke of Savoy. His best-known literary work is a burlesque epic entitled *La Secchia Rapita*, or "The Rape of the Bucket" (1622), the reference being to a raid of the Modenese upon the people of Bologna in 1325, when a bucket was carried off as a trophy. As in Butler's *Hudibras*, many of the personal and local allusions in this poem are now very obscure, and are apt to seem somewhat pointless to the general reader, but, in spite of Voltaire's contempt, it cannot be neglected by any systematic student of Italian literature (compare vol. xiii. p. 522). Other characteristic works of Tassoni are his *Pensieri Diversi* (1612), in which he treats philosophical, literary, historical, and scientific questions with unusual freedom, and his *Considerazioni sopra il Petrarcha* (1609), a piece of criticism showing great independence of traditional views.

TASTE is the sensation referred to the mouth when certain soluble substances are brought into contact with the mucous membrane of that cavity. The sense is located almost entirely in the tongue. Three distinct sensations are referable to the tongue—(1) taste, (2) touch, and (3) temperature. The posterior part of its surface, where there is a ∧-shaped group of large papillæ, called circumvallate papillæ, supplied by the glosso-pharyngeal nerve, and the tip and margins of the tongue, covered with filiform (touch) papillæ and fungiform papillæ, are the chief localities where taste is manifested, but it also exists in the glosso-palatine arch and the lateral part of the soft palate. The middle of the tongue and the surface of the hard palate are devoid of taste. The terminal organs of taste consist of peculiar bodies named taste-bulbs or taste-goblets, discovered by Schwalbe and Lovèn in 1867. They can be most easily demonstrated in the *papillæ foliatæ*, large oval prominences found on each side near the base of the tongue in the rabbit. Each papilla consists of a series of laminæ or folds, in the sides of which the taste-bodies are readily displayed in a transverse section. Taste-bodies are also found on the lateral aspects of the circumvallate papillæ (see Fig. 1), in the fungiform papillæ, in the papillæ of the soft palate and uvula, the under surface of the epiglottis, the upper part of the posterior surface of the epiglottis, the inner sides of the arytenoid cartilages, and even in the vocal cords.

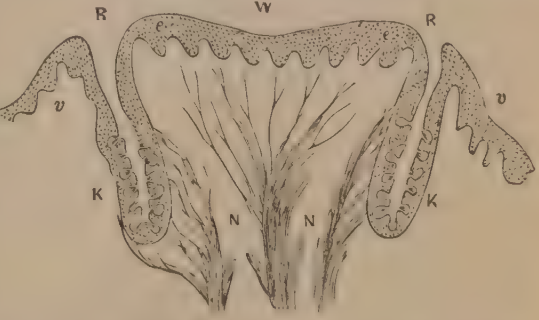

Fig. 1.—Transverse section of a circumvallate papilla; W, the papilla; v, v, the wall in section; R, R, the circular slit or fossa; K, K, the taste-bulbs in position; N, N, the nerves. The figures are from Landois and Stirling's *Physiology*.

The taste-bulbs are minute oval bodies, somewhat like an old-fashioned Florence flask, about $\frac{1}{300}$ inch in length by $\frac{1}{800}$ in breadth. Each consists of two sets of cells,—an *outer* set, nucleated, fusiform, bent like the staves of a barrel, and arranged side by side so as to leave a small opening at the apex (the mouth of the barrel), called the gustatory pore; and an *inner* set, five to ten in number, lying in the centre, pointed at the end next the gustatory pore, and branched at the other extremity. The branched ends are continuous with non-medullated nerve fibres from the gustatory nerve. These taste-bodies are found in immense numbers: as many as 1760 have been counted on one circumvallate papilla in the ox. They are absent in reptiles and birds. F. E. Schultze states that they exist in the mouth of the tadpole, whilst the tongue of the frog is covered with epithelium resembling that of the gustatory bodies. Leydig has described organs having a similar structure in the skins of freshwater fishes and the tadpole: these may possibly be widely distributed taste-organs. The proofs that these are the terminal organs of taste rest on careful observations which have shown (1) that taste is only experienced when the sapid substance is allowed to come in contact with the taste-body, and that the sense is absent or much weakened in those areas of mucous membrane where these are deficient; (2) that they are most abundant where the sense is most acute; and (3) that section of the glosso-pharyngeal nerve which is known to be distributed to the areas of mucous membrane where taste is present is followed by degeneration of the taste-bodies. At the same time it cannot be asserted that they are absolutely essential to taste, as we can hardly suppose that those animals which have no special taste-bodies are devoid of the sense.

Taste is no doubt closely allied to smell; hence in invertebrates organs are found that may be referred to either of the senses (see SMELL). Tastes have been variously classified. One of the most useful classifications is into sweet, bitter, acid, and saline tastes. To excite the sensation substances must be soluble in the fluid of the mouth. Insoluble substances when brought into contact with the tongue, give rise to feelings of touch or of temperature, but excite no taste. The specific mode of action of sapid substances is quite unknown. The extent of surface acted on increases the massiveness of the sensation, whilst the intensity is affected by the degree of concentration of the solution of the sapid substance. If solutions of various substances are gradually diluted with water until no taste is experienced, Valentine found that the sensations of taste disappeared in the following order: syrup, sugar, common salt, aloes, quinine, sulphuric acid; and Camerer found that the taste of quinine still continued although diluted with twenty times more water than common salt. Von Vintschgau found that the time required to excite taste after the sapid substance was placed on the tongue varied. Thus saline matters are tasted most rapidly (.17 second), then sweet, acid, and bitter (.258 second). This is probably due to the activity of diffusion of the substance. No relation between the chemical constitution of the substance and the nature of the taste excited by it has yet been discovered, and there are many curious examples of substances of very different chemical constitutions having similar tastes. For example, sugar, acetate of lead, and the vapor of chloroform have all a sweetish taste. A temperature of from 50° to 90° F. is the most favorable to the sense, water above or below this temperature either masking or temporarily paralyzing it. Taste is often associated with smell, giving rise to a sensation of flavor, and we are frequently in the habit of confounding the one sensation with the other. Chloroform excites taste alone, whilst garlic, asafœtida, and vanilla excite only smell. This is illustrated by the familiar experiment of blindfolding a person and touching the tongue successively with slices of an apple and of an onion. In these circumstances the one cannot be distinguished from the other when the nose is firmly closed. No doubt also experience aids in detecting slight differences of taste by suggesting to the mind what may be expected; it is not easy, for instance, to distinguish the tastes of red and white wine when the eyes are blindfolded. Taste may be educated to a remarkable extent; and careful observation—along with the practice of avoiding all substances having a very pronounced taste or having an irritating effect—enables tea-tasters and wine-tasters to detect slight differences of taste, more especially when combined with odor so as to produce flavor, which would be quite inappreciable to an ordinary palate. As to the action of electrical currents on tastes, observers have arrived at uncertain results. So long ago as 1752 Sulzer stated that a constant current caused, more especially at the moments of opening and of closing the current, a sensation of acidity at the anode (+ pole) and of alkalinity at the katode (— pole). This is in all probability due to electrolysis, the decomposition products exciting the taste-bodies. Grünhagen found that rapidly interrupted currents fail to excite the sense; Von Vintschgau who has directed much attention to the sense of taste, says that when the tip of his tongue is traversed by a current there is only a tactile sensation. Again, Hönigschmied, on the contrary, found that a current excited the metallic or acid taste at the anode placed on the tip of the tongue, whilst the alkaline taste of the katode was absent. The writer of this article has found that this is the experience of most persons examined by him.

Disease of the tongue causing unnatural dryness may interfere with taste. Substances circulating in the blood may give rise to subjective sensations of taste. Thus santonine, morphia, and biliary products (as in jaundice) usually cause a bitter sensation, whilst the sufferer from diabetes is distressed by a persistent sweetish taste. The insane frequently have subjective tastes, which are real to the patient, and frequently cause much distress. In such cases, the sensation is excited by changes in the taste-centres of the brain. Increase in the sense of taste is called *hypergeusia*, diminution of it *hypogeusia*, and its entire loss *ageusia*. Rare cases occur where there is a subjective taste not associated with insanity nor with the circulation of any known sweetish matters in the blood, possibly caused by irritation of the gustatory nerves or by changes in the nerve centres.

As to the comparative anatomy of the tongue, see Owen's *Comparative Anatomy and Physiology of Vertebrates* (London, 1868). For a full account of the physiology of taste, see Von Vintschgau's article "Geschmackssinn," in *Hermann's Handbuch der Physiologie*, vol. iii. part ii. (J. G. M.)

TATARS. See TARTARS.

TATE, NAHUM (1652–1715), poet-laureate, was born in 1652 in Dublin, and was educated at Trinity College there. He afterwards removed to London, and adopted literature as a profession, succeeding Shadwell as poet-laureate in 1692. He died within the precincts of the Mint, Southwark (whither he had taken refuge from his debtors), August 12, 1715.

His name is still remembered in connection with the *New Version of the Psalms of David*, which, in conjunction with Nicholas BRADY (*q.v.*), he published in 1696 (see HYMNS, vol. xii. p. 625). Tate was also the author of some ten dramatic pieces (see *Biogr. Dramatica*, i. 703) and a great number of poems, including one entitled *The Innocent Epicure, or the Art of Angling* (1697).

TATIAN, one of the earliest Christian apologists, whose personality and work had an important influence on the history of the church during the period of the Antonines. He was by birth an Assyrian (according to Zahn of Semitic descent), but received a Greek education, and, after acquiring a very extensive knowledge of Greek literature, began to travel about the Roman empire as a wandering teacher or "sophist." But his inquiring disposition and his earnest spirit remained unsatisfied alike with the religions and the philosophies he encountered, while the doings of men, their greed for amusement and pleasure, their vanity and treachery, disgusted him. In this temper, about 150 A.D., he reached Rome, where the Old Testament fell into his hands, and at the same time he came into closer relations with the Christians; their firm faith, chaste morals, fearless courage, and close fellowship deeply impressed him, and in the end the spectacle of their life and their monotheistic doctrine founded upon prophetic revelation completely conquered him. Henceforward the whole unchristian world, with all its philosophy and culture, presented itself to him as mere darkness and the deception of demons, but the "barbarian philosophy" (for so he called Christianity) as the wisdom of God. He became a convert, and soon afterwards (152–153) wrote (most probably in Greece, where he stayed for some time) his *Oratio ad Græcos*, which gained him great repute among the Christians, and is still extant. This discourse is distinguished from the other apologies of that century by the brusqueness with which its author repudiates the culture of the Greeks; his scorn, however, does not forget to avail itself of the resources of Greek philosophy and rhetoric. His polemic often reminds the reader of the Cynics and of such scoffers as Lucian; his view of things, however, is very different from that of the last-named writer, for with Tatian the "barbarian philosophy," on behalf of which he speaks, which teaches a monotheistic cosmology and inculcates rigid asceticism and renunciation of the world, is indisputably certain. In many details, and even in the general outline of his philosophy, Tatian the Christian continued without knowing it to be a Platonizing philosopher; but that he had undergone a radical change is shown by his views of history and civilization, his faith in one living God, his conviction that truth is contained nowhere else than in the Christian Scriptures, his attitude of trust towards the Logos, made man in Jesus Christ, and finally by his earnest and world-forsaking expectation of judgment to come. The *Oratio*, which is polemical rather than apologetic in its character, has a special importance in the history of Christian dogma, inasmuch as it gives an elaborated exposition of the doctrine of the Logos; it was also read by subsequent writers, as, for example, by Julius Africanus, for its chronological data. Tatian was the first apologist to undertake, on behalf of Christianity, a work of the class which afterwards developed into the numerous "world-histories" written from the Christian point of view. Tatian's diction is often rough, harsh, and abrupt, his sentences involved and inelegant. He has the art, indeed, of expressing himself with uncommon freedom and independence, and can put things also in a very graphic way, but at the same time he is a careless stylist, or rather, as an apostate from the Greek view of things, he has tried to accentuate his breach with classical traditions by elaborate carelessness and deliberate eccentricity.

Tatian soon returned from Greece to Rome, and came into close relations with the famous apologist Justin, whom he reverenced greatly. He himself established a school, to which the afterwards celebrated ecclesiastical writer Rhodon belonged for a time. So long as Justin lived (*i.e.*, till 166) Tatian's doctrines excited no feelings of offence in the Christian community, although even in his *Oratio* there are germs of questionable and unorthodox views. These germs, however, he continued to develop until about 172; and, as about this very time the Roman church became severely opposed to everything Gnostic and heretical, a rupture was inevitable; the date of the breach is given by Eusebius (doubtless following Julius Africanus) as having been 172. But the teaching of Tatian had really become open to challenge. He drew a distinction between the supreme God and the demiurge, considering the latter to be good in his nature indeed, but quite a subordinate being; he accepted the doctrine of a variety of æons; he utterly rejected marriage and the use of animal food; he denied the blessedness of Adam; he began to abandon the allegorical interpretation of the Scriptures and to see genuine difficulties and contradictions in them; he sought to demonstrate from the epistles of Paul the indispensableness of the most rigid asceticism; but indeed all his "heresies" (and he has also been charged with docetism) have their explanation in this desire of his to establish a theoretical basis for his doctrine of the Christian duty of complete world-renunciation. He joined the "Encratites," a sect which indeed had existed before this time, but which received new life from his presence. Of his numerous writings belonging to this period nothing has survived the hostility which sought their repression save a few titles (*βιβλίον προβλημάτων, περὶ τοῦ κατὰ τὸν σωτῆρα καταρτισμοῦ*, etc.) and one or two very interesting fragments in the works of Clement of Alexandria, Origen, and Jerome. Clement of Alexandria seems personally to have known Tatian, and even to have been his pupil for a time. Soon Tatian began also to be assailed in writing by the teachers of the church, and to be set aside as a very prodigy among heretics, and as a man who united the errors of Marcion with those of Valentine. Musanus, Rhodon, Irenæus, the author of the Muratorian fragments (see below), Tertullian, Hippolytus, Clement of Alexandria, and Origen all took part in refuting him.

Towards the end of his life, or perhaps even between 152 and 172, Tatian went from Rome to Mesopotamia, and there—probably in Edessa—wrought a great deal. It is probable that he was in Rome about the year 172, but whether he died there or in his native country is not ascertained. It is very possible that in Syria, where ecclesiastical matters had not been developed so far as in the west, the doctrines of Tatian met with toleration within the Christian communities, but neither of this can we be certain.[1] But this we do know, that a work of Tatian's not yet mentioned, the *Diatessaron*, held its ground in the Syrian churches and even in ecclesiastical use for two whole centuries.

The *Diatessaron* is a gospel very freely and boldly constructed by Tatian out of the four gospels known to us. It cannot have been produced during his latter years, for all traces of dualism are absent. On the other hand, however, it exhibits certain peculiarities of the theology of its compiler. Probably one would not be far wrong in assigning it to the first years of the reign of Marcus Aurelius. It was written by Tatian in Greek, not in Syriac as Zahn has tried to make out; this is shown—(1) by the title, it being known even among the Syrians as *Diatessaron;* (2) by a few Greek fragments which still survive; (3) by the Latin redaction which it received in the 6th century; (4) by its rejection in the Muratorian fragment—for that the word "m-tia-i," carelessly corrected by the transcriber, stood originally "tatiani" may be regarded as certain.[2] In estimating the work scholars were formerly entirely dependent on certain meagre notices in Eusebius, Theodoret, Ephraem Syrus, Epiphanius, and the later Syrians,[3] but we have recently become possessed of large portions of it, and are now in a position to form for ourselves an idea of its character and plan. In 1877 there was published[4] a Latin translation, by Aucher the Mechitarist, of Ephraem's gospel commentary, which had been preserved in Armenian, and it then became apparent that Ephraem had taken the *Diatessaron* as his basis. This led to further research.[5] Recognizing with other scholars that other Syrian writers also, down to the middle of the 4th century, had used the *Diatessaron* (Theodoret tells us that in his diocese alone he caused more than 300 copies to be withdrawn from use), Zahn undertook the laborious task of restoring the work with the help of Ephraem's commentary and other sources.[1] In details much of what Zahn has given us belonging to the text of the *Diatessaron* remains problematical,—in particular he has not been sufficiently careful in his examination of the work of Aphraates,—but in all the main points his restoration has been successful. The rediscovery of such a work is in a variety of ways of the very highest importance for the early history of Christianity. (1) It is of interest for the history of the canon. It shows that in Tatian's time there was still no recognized New Testament canon, and that the texts of the Gospels were not regarded as inspired. He could not possibly have treated them with such freedom had they been held to be otherwise. But the ecclesiastical use made of his work in Syria shows that Tatian intended it for the church, and, as we are informed further by Eusebius that Tatian also edited the Pauline epistles, we are entitled to conclude that, like Marcion, he wished to frame a special New Testament canon. (2) It is of importance for the Gospels as we now have them. We learn from the *Diatessaron* that about 160 A.D. our four Gospels had already taken a place of prominence in the church and that no others had done so; that in particular the Fourth Gospel had taken a fixed place alongside of the three synoptics. (3) As regards the text of the Gospels, we can conclude from the *Diatessaron* that the texts of our Gospels about the year 160 already ran essentially as we now read them, but that intentional changes were not wanting about the middle of the 2d century. Thus, for example, Tatian in his Gospel according to Matthew found nothing about the "church" and about the building of the church upon Peter the rock. These sentences therefore are very probably of later interpolation. (4) It is of importance for the light it throws on Tatian's Christianity. The Syriac translation of the *Diatessaron* still falls within the 2d century, but Zahn was mistaken in assuming it to presuppose a prior Syriac translation of the separate Gospels (the so-called *Syrus Curetonianus*); Baethgen[2] has shown the latter to be the later. It was only gradually that the "evangelium der Getrennten" superseded the "evangelium der Gemischten."[3]

TATIUS, ACHILLES. See ROMANCE, vol. xx. p. 651 *sq.*

TAULER, JOHANN (*c.* 1300–1361), was born about the year 1300 in Strasburg, where his father was a wealthy burgher. It is probable that he entered the Dominican convent in his native city about the year 1313, while Meister Eckhart was still professor of theology (1312–1320) in the monastery school. From Strasburg he went to the Dominican college of Cologne, and some believe that his superiors sent him a few years later to St. James's College, Paris. After his theological education was finished he returned to Strasburg. In 1324 the pope placed under an interdict these parts of Germany, including Strasburg, which supported the excommunicated emperor Louis of Bavaria. It was one of the privileges of the Dominican and Franciscan orders to be allowed to perform religious services when the secular and all other regular clergy were silenced by an interdict. The Dominican order, however, had taken the side of Frederick, and in most places refused to say mass; but in Strasburg they remained in the deserted city, kept their churches open, and administered to the citizens the consolations of religion. It is supposed that this conduct of the Strasburg Dominicans was due to the influence of Tauler. In 1339 the heads of the order interfered and commanded the monks to close their churches. The town council in return banished the Dominicans from the city. Tauler, with some of his brethren, found refuge in Basel, although that city, like Strasburg, sided with the emperor. During these years Basel was the headquarters of the "Friends of God" (*Gottesfreunde*, see MYSTICISM, vol. xvii. p. 140), and Tauler was brought into intimate relations with the members of that pious mystical fellowship. He returned to Strasburg probably in the year 1346. It is somewhat difficult to trace his later life. The Black Death came to Strasburg in 1348, and it is more than probable that, when the city was deserted by all who could leave it, Tauler remained at his post, encouraging by sermons and personal visitations his terror-stricken fellow-citizens. His correspondence with distinguished members of the *Gottesfreunde*, especially with Margaretha Ebner, and the fame of his preaching and other work in Strasburg, had made him known throughout a wide circle of pious people. He seems to have made preaching journeys, in the later years of his life, to Cologne and to other places in the Rhineland. He died in the year 1361.

It is somewhat difficult to form an estimate of the religious life and opinions of Tauler. For many years the chief modern authority upon the subject was the late Prof. C. Schmidt, of Strasburg, whose views had been introduced into England in Miss Winkworth's book upon Tauler. According to Schmidt, Tauler's religious life divides into two parts, before and after what may be called his second conversion. In the first period Eckhart rules his religious life; in the second he is under the influence of the mysterious "Friend of God in the Oberland," whom Schmidt asserts to be Nicholas of Basel. Denifle doubts the historical character of this episode and the genuineness of the book, while Preger admits the fact of the conversion, but refuses to identify the mysterious stranger with Nicholas of Basel.

It is still more difficult to determine the precise nature of the theological opinions of Tauler. Denifle maintains that the only genuine remains of Tauler are the eighty well-known *Sermons* included in the earliest edition and four others in two manuscripts, all of which bear Tauler's name; Preger seems inclined to admit in addition the *Sermons* in the account of Tauler's conversion; both critics exclude the famous *Book of Spiritual Poverty*. Schmidt, on the other hand, while admitting the authenticity of all the above-named sermons, calls the *Book of Spiritual Poverty* Tauler's masterpiece.

If we take the *Sermons* by themselves, then Tauler's teachers in theology were the Pseudo-Dionysius, Augustine, Gregory, Bernard, the two abbots of St. Victor, Thomas Aquinas, and, above all, Theodoric of Freiburg and Meister Eckhart. His theology will represent the purest and highest type of German mysticism (see MYSTICISM), and, by insisting upon personal relationship to God, freedom from the thraldom of authority, and the worthlessness of mere good works without the renewal of the inward life, will represent a tendency in theology which found full expression in the reformation of the 16th century. If, on the other hand, the *Book of Spiritual Poverty* be included among the genuine writings of Tauler, then undoubtedly his views have more distinct connection with that doctrine of the appropriation of the benefits of Christ's work of redemption by an *imitatio Christi* finding expression in a life of evangelical poverty which is such a characteristic of the religious life of the century to which he belonged. The problem is a very difficult one, and it may be questioned whether we are yet in a position to solve it. Denifle is undoubtedly correct in his statement that we need critical texts of 14th century mystical writers, and that very great uncertainty exists with reference to the authors of the individual mystical writings of that period. It may be added that it is very probable, when the organization and method of work among the "Friends of God" are taken into consideration, that many mystical books of devotion were the work, not of one, but of several authors, and that the conditions of the problem concerning the authenticity of Tauler's writings are not unlike those which exist among the books and tracts ascribed to Wickliffe. This at all events may be safely asserted, that Tauler's sermons are among the noblest in the German language. They are not so emotional as Suso's, nor so speculative as Eckhart's, but they are intensely practical, and touch on all sides the deeper problems of the moral and spiritual life.

Tauler's *Sermons* were printed first at Leipsic in 1498, and reprinted with additions from Eckhart and others at Basel (1521, 1522) and at Cologne (1543). There is a recent edition by Julius Hamberger, Frankfort, 1864. See Denifle, *Das Buch von geistlicher Armuth*, 1877; Carl Schmidt, *Johann Tauler von Strassburg*, Hamburg, 1841; Miss Winkworth, *Tauler's Life and Sermons*; R. A. Vaughan. *Hours with the Mystics*, 3d ed., vol. i. pp. 214-307. The third volume of Preger's *Gesch. der deutschen Mystik im Mittelalter*, which will treat of Tauler, is in the press.

TAUNTON, a municipal borough and market-town of Somerset, England, is situated in the beautiful and fertile vale of Taunton Dene, on the river Tone, on the Taunton and Bridgewater Canal, and on several branches of the Great Western Railway, 45 miles south-southwest of Bristol, 31 northeast of Exeter, and 163 west-southwest of London. The river is crossed by a stone bridge of three arches. The town is well built, the three main streets being wide and regular, and meeting in a triangular space in the centre called the Parade, where there is a market cross. The castle, now occupied by the museum of the Somerset Archæological and Natural History Society, is reputed to have been founded by Ine, king of the West-Saxons. The earliest portion of the present building was erected by Walter Giffard, bishop of Winchester, in the time of Henry I., but the whole building was repaired in 1496, and an embattled gateway erected by Bishop Langton. The church of St. Mary Magdalene, a spacious building with double aisles both north and south of the nave, is chiefly Perpendicular, but has remains of Norman work in the chancel arch, and of Early English in the north aisles and transepts. It possesses one of the finest of the characteristic towers of Somerset, but only a facsimile reproduction (erected 1857–62) of the old one. There are still some remains of the Augustinian priory founded by Bishop Giffard, and there are also two modern convents. Taunton is an important centre of education, the principal institutions being the grammar school (founded in 1522 by Richard Fox, bishop of Winchester), Huish's schools, the Independent college (1841), and the Wesleyan collegiate institution (1847). The other principal public buildings are the old market-house, the assembly rooms, the new market in the Ionic style, and the shire hall in the Elizabethan style, opened in 1858 at a cost of £28,000 [$136,080]. The charitable institutions include the Taunton and Somerset hospital (opened in 1809 and extended in 1870 and 1873), the eye infirmary (1816), Gray's almshouses and chapel (1635), St. Saviour's home for boys (1870), and the servants' training home (1882). The town possesses manufactories of silk, collars and cuffs, and gloves, iron and brass foundries, coach-building works, and breweries. There is also a considerable agricultural trade. The population of the municipal and parliamentary borough (area 1249 acres) in 1881 was 16,614. The population of the same area in 1871 was 15,466.

Taunton has played a prominent part during the troubled periods of English history. Various Roman remains prove it to have been occupied by the Romans; but it first obtained historical notice when Ine, king of the West-Saxons, made it the border fortress of his kingdom. It takes the name Taunton, or Thoneton, from its situation on the Tone or Thone. The castle was razed by Ethelburg after expelling Edbricht, king of the South-Saxons. About the time of William the Conqueror the town and castle were granted to the bishop of Winchester, and for many years the castle was the bishop's principal residence. In the reign of William it possessed a mint. In 1497 the town and castle were seized by the impostor Perkin Warbeck. Taunton was made the seat of the suffragan see of Taunton and Bridgwater in 1538, but, on the death of William Finch, the first bishop, in 1559, the Act had no further operation in reference to Taunton. Like the other towns of Somerset, Taunton was strongly Puritan in its sympathies. Situated at a point where the main roads of the county met, it was during the Civil War almost constantly in a state of siege by one or other of the rival parties. Having been garrisoned by the Parliamentary forces, it was captured by the Royalists in the summer of 1643, but on 8th July, 1644, it was, after a long siege, taken by Blake, who held it with heroic pertinacity till relieved by Fairfax on the 11th May, 1645, and again after it was invested by 10,000 troops under Goring till the siege was finally raised on the 3d July. Still constant to its Puritan traditions, Taunton welcomed Monmouth in 1685 with acclamation, and he was proclaimed king there on the 20th June, the maidens of the town presenting him with a standard. As a consequence, Taunton was made the chief example of the fearful vengeance of Jeffreys, who, at the assizes held in the castle, condemned no fewer than 134 inhabitants of the town and neighborhood to death, and a much larger number to transportation. Taunton obtained a municipal charter from Charles I. in 1627, which was revoked in 1660. A second charter, granted by Charles II. in 1677, was permitted to lapse in 1792 owing to the corporation allowing a majority of their number to die without filling up the vacancies. From this time until it again received municipal government, 17th April, 1877, it was under the care of two bailiffs appointed at the court leet of the lord of the manor. Formerly the town returned two members to parliament, but in 1885 the number was reduced to one.

See Toulmin's *History of Taunton*, edited by Savage, 1822; and several papers in the *Proceedings* of the Somerset Archæological Society for 1872.

TAUNTON, a city of the United States, the county seat of Bristol county, Massachusetts, lies some 31 miles nearly south from Boston. The town proper, sometimes called Taunton Green, stands on the right bank of the Taunton river, at the head of navigation, about 17 miles above its mouth. The entire area enclosed within the corporate limits is 37 square miles. Taunton is traversed by the main line of the Old Colony Railway, which connects it with Boston and Fall River, Mass., and Providence, R. I. Owing to its situation and its connections by rail and sea, Taunton has become a supply point for the greater part of southeastern Massachusetts. The population of the city was 18,629 in 1870, 21,213 in 1880, and 23,674 in 1885, showing an increase somewhat in excess of that of the State at large. Fully one-fourth of the population are of foreign birth, and the proportion is increasing. The State lunatic asylum is in Taunton. The leading industries are the manufacture of cotton goods, iron and steel products (particularly locomotives, machinery, nails and spikes), and silver-plated table ware. Taunton was incorporated as a town in 1639, and received a city charter in 1864.

TAURIDA, a government of southern Russia, includes the peninsula of CRIMEA (*q.v.*) and a tract of mainland situated between the lower Dnieper and the coasts of the Black Sea and the Sea of Azoff, and is bounded by these two seas on the S., while it has on the N. the governments of Kherson and Ekaterinoslaff. The area is 24,540 square miles, of which 6990 square miles belong to the Crimea; its continental part consists of a gently undulating steppe of black earth, with only a few patches of salt clay on the banks of the Sivash or Putrid Sea, and sands in the lower course of the Dnieper. It is watered by the Dnieper, which flows along the frontier for 180 miles, and by two small rivers, the Molotchnaya and Berda. Many small lakes and ponds occur in the north, especially among the Dnieper sands, as well as on the Kinburn peninsula, at the mouth of the Dnieper, where salt is made. There are no forests except the artificial plantations in the colonies of the Mennonites. The climate is continental, and resembles that of central Crimea and Kherson. The population in 1883 was 940,530 (247,780 in Crimea). The continental portion, although less mixed than that of the peninsula, consists of Russians (Great, Little, and White Russians), who constitute 83 per cent. of the population, Germans (11 per cent.), Bulgarians (5 per cent.), and Jews (1 per cent.).

Agriculture and cattle-breeding are the leading occupations. Wheat is the chief product, and by the Germans and Russian Non-conformists on the Molotchnaya agriculture is carried to a high degree of perfection. In 1882 there were within the government 356,270 horses, 485,800 cattle, and 3,985,300 sheep (2,891,700 merinos). Salt is made both on the mainland and in the Crimea, and the fisheries along the coast supply an export trade. Manufactures are insignificant, but there is a brisk export trade in grain, salt, fish, wool, and tallow. The main centres of trade are the Kakhovka port on the Dnieper, Berdyansk on the Sea of Azoff, and the seaports of Eupatoria, Sebastopol, Sudak, and Theodosia. The government is divided into eight districts, the chief towns of which (with populations in 1881) are Simferopol (29,030), capital of the government, Eupatoria (13,420), and Theodosia (10,800) in Crimea, and Aleshki (8915), Berdyansk (18,180), Melitopol (13,310), Perekop (4280), and Yalta (3000) on the continent. Several villages, such as Bolshoy Tokmak (8000) and Andreevka (7300), have each a population of more than 5000.

TAUROMENIUM. See TAORMINA.

TAURUS. See ASIA MINOR, vol. ii. pp. 615–616.

TAVERNIER, JEAN BAPTISTE (1605–1689), the celebrated traveller and pioneer of French trade with India, was born (1605) at Paris, where his father Gabriel and uncle Melchior, Protestants from Antwerp, pursued with reputation and success the profession of geographers and engravers. The conversations he heard in his father's house inspired Jean Baptiste with an early desire to travel, and in his sixteenth year he had already visited England, the Low Countries, and Germany, and seen something of war with the imperialist Colonel Hans Bremner, whom he met at Nuremberg. Four and a half years in the household of Bremner's uncle, the viceroy of Hungary (1624–29), and a briefer connection in 1629 with the duke of Rethel and his father the duke of Nevers, prince of Mantua, gave him the habit of courts, which was invaluable to him in later years, and at the defence of Mantua in 1629, and in Germany in the following year with Colonel Walter Butler (afterwards notorious through the death of Wallenstein), he gained some military experience. When he left Butler to view the diet of Ratisbon in 1630, he had seen Italy, Switzerland, Germany, Poland, and Hungary, as well as France, England, and the Low Countries, and spoke the principal languages of these regions. He was now eager to visit the East, and at Ratisbon he found the opportunity to join two French fathers, M. de Chapes and M. de St. Liebau, who had received a mission to the Levant. In their company he reached Constantinople early in 1631, and here he spent eleven months, and then proceeded by Tokat, Erzerum, and Erivan to Persia. His farthest point in this first journey was Ispahan; he returned by Baghdad, Aleppo, Alexandretta, Malta, and Italy, and was again in Paris in 1633. Of the next five years of his life nothing is known with certainty, but it is probable that it was during this period that he became controller of the household of the duke of Orleans. In September, 1638, he began a second journey (1638–43) by Aleppo to Persia and thence to India as far as Agra and Golconda. His visit to the court of the Great Mogul and to the famous diamond mines was, of course, connected with the plans realized more fully in his later voyages, in which Tavernier travelled as a merchant of the highest rank, trading in costly jewels and other precious wares, and finding his chief customers among the greatest princes of the East. The second journey was followed up by four others. In his third journey (1643–49) he went as far as Java and returned by the cape; but his relations with the Dutch proved not wholly satisfactory, and a long lawsuit on his return yielded but imperfect redress. In his last three journeys (1651–55, 1657–62, 1664–68) he did not proceed beyond India. The details of these voyages need not detain us here, and indeed are often obscure; but they completed an extraordinary knowledge of the routes of overland Eastern trade, and brought the now famous merchant into close and friendly communication with the greatest Oriental potentates. They also secured for him a large fortune and great reputation at home. He was presented to Louis XIV., "in whose service he had travelled sixty thousand leagues by land," received letters of nobility (16th February, 1669), and in the following year purchased the barony of Aubonne, near Geneva. In 1662 he had married Madeleine Goisse, daughter of a Parisian jeweller.

Thus settled in ease and affluence, Tavernier occupied himself, as it would seem at the desire of the king, in publishing the account of his journeys. He had neither the equipment nor the tastes of a scientific traveller, but in all that referred to commerce his knowledge was vast and could not fail to be of much public service. He set to work therefore with the aid of Samuel Chappuzeau, a French Protestant littérateur, and produced a *Nouvelle Relation de l'Intérieur du Sérail du Grand Seigneur* (4to, Paris, 1675), based on two visits to Constantinople in his first and sixth journeys. This was followed by *Le Six Voyages de J.B. Tavernier* (2 vols. 4to, Paris, 1676) and by a supplementary *Recueil de Plusieurs Relations* (4to, Paris, 1679), in which he was assisted by a certain La Chapelle. This last contains an account of Japan, gathered from merchants and others, and one of Tong-king, derived from the observations of his brother Daniel, who had shared his second voyage and settled at Batavia; it contained also a violent attack on the agents of the Dutch East India Company, at whose hands Tavernier had suffered more than one wrong. This attack was elaborately answered in Dutch by H. van Quellenburgh (*Vindiciæ Batavicæ*, Amst., 1684), but made more noise because Arnauld drew from it some material unfavorable to Protestantism for his *Apologie pour les Catholiques* (1681), and so brought on the traveller a ferocious onslaught in Jurieu's *Esprit de M. Arnauld* (1684). Tavernier made no reply to Jurieu; he was in fact engaged in weightier matters, for in 1684 he travelled to Berlin at the invitation of the Great Elector, who commissioned him to organize an Eastern trading company,—a project never realized. The closing years of Tavernier's life are obscure; the time was not favorable for a Protestant, and it has even been supposed that he passed some time in the Bastille. What is certain is that he left Paris for Switzerland in 1687, that in 1689 he passed through Copenhagen on his way to Persia through Muscovy, and that in the same year he died at Moscow. It appears that he had still business relations in the East, and that the neglect of these by his nephew, to whom they were intrusted, had determined the indefatigable old man to a fresh journey.

Tavernier's travels, though often reprinted and translated, have two defects; the author uses other men's material without distinguishing it from his own observations; and the narrative is much confused by his plan of often deserting the chronological order and giving instead notes from various journeys about certain routes. The latter defect, it is true, while it embarrasses the biographer, is hardly a blemish in view of the object of the writer, who sought mainly to furnish a guide to other merchants. A careful attempt to disentangle the thread of a life still in many parts obscure has been made by Charles Joret, *Jean Baptiste Tavernier d'après des Documents Nouveaux*, 8vo, Paris, 1886, where the literature of the subject is fully given.

TAVIRA, a seaport of Portugal, in the province of Algarves, at the mouth of the Seca, 21 miles east-northeast of Faro. It is regularly built, and has an alcazar, used as an official residence, besides other public buildings. It has sardine and tunny fisheries, and carries on a considerable coasting trade. Excellent fruit is grown in the neighborhood. The population in 1878 was 11,459.

TAVISTOCK, a town of Devonshire, England, is finely situated in the valley of the Tavy, on the western border of Dartmoor, and on the South Devon Railway, 15 miles north of Plymouth, 14 southeast of Launceston, and 213 west-southwest of London. The town has been greatly improved since 1845, chiefly at the expense of the duke of Bedford, by the construction of a system of sewage and the erection of many new dwellings suitable for the working classes. There are some remains (including a portion in the square, now used as a public library established in 1799) of the magnificent abbey of Sts. Mary and Rumon, first founded in 961 by Orgar, earl of Devon. After destruction by the Danes in 997 it was restored, and among its famous abbots were Lyfing, friend of Canute, and Aldred, who crowned Harold II. and William, and died archbishop of York. The abbey church was rebuilt in 1285, and the greater part of the abbey in 1457–58. The church of St. Eustachius possesses a lofty tower supported on four open arches. Among the principal public buildings are the guildhall (1848), the corn market (1838), the market buildings (1858), and the new hall for concerts and public entertainments. Near the town is Kelly College, opened in 1877, founded by Admiral Benedictus Marwood Kelly, with a preference for the founder's kin. Mines of copper, manganese, lead, silver, and tin are in the neighborhood, and the town possesses a considerable trade in cattle and corn, as well as a brewery. The population of the township in 1881 was 6914. The parliamentary borough (area 11,450 acres), which had a population in 1871 of 7725 and in 1881 of 6879, was merged in the county in 1885.

The town owes its origin to the foundation of the abbey in 961. From Henry I. the abbots obtained the entire jurisdiction of the hundred of Tavistock, with a weekly market. A school for Saxon literature was established by the monks, which flourished till the Reformation. The Royalists were quartered at Tavistock after the defeat of the Parliamentarians on Bradock Down in 1643, and Charles I. visited it on his way to Cornwall. It returned members to parliament from the time of Edward I. till 1885, among its representatives having been John Pym, the great opposer of the policy of Charles I., and William, Lord Russell, beheaded in the reign of Charles II. Among the famous natives of Tavistock are Sir John Glanville, judge under James I., William Brown, the author of *Britannia's Pastorals*, and Sir Francis Drake, of whom a colossal statue by Boehm was presented to the town by the duke of Bedford in 1883.

TAVOY, a British district in the Tenasserim division of Burmah, lying between 13° 15′ and 15° 11′ N. lat. and between 97° 48′ and 98° 44′ E. long. It has a area of 7200 square miles, and is bounded on the N. by Amherst district, E. by the Yoma Mountains, S. by Mergui district, and W. by the Bay of Bengal. The district is enclosed by mountains on three sides, viz., the main chain of the Yomas on the east, rising in places to 5000 feet, which, with its densely wooded spurs, forms an almost impassable barrier between British and Siamese territory; the Nwahlabo in the centre, which takes its name from its loftiest peak (5000 feet); and a third range, under the name of Thinmaw, between the Nwahlabo and the sea-coast. The chief rivers are the Tennasserim and Tavoy, the former being formed by the junction of two streams which unite near Met-ta; for the greater part of its course it is dangerous to navigation. The Tavoy is navigable for vessels of any burden. It is interspersed with many islands, and with its numerous smaller tributaries affords easy and rapid communication over the country. The climate is on the whole pleasant. The rainfall averages about 190 inches a year.

The census of 1881 returned the population of Tavoy at 84,988 (males 41,785, females 43,203), of whom 82,187 were Buddhists, 828 were Mohammedans, and 1368 were Christians. The headquarters and capital is Tavoy town, which is situated on the left bank of the river of the same name, and contained a population of 13,372 in 1881. Of the total area, only 83,740 acres are (1885–86) cultivated. Rice is the principal product; the betel-nut is extensively grown for home consumption; and the district is particularly rich in fruit trees. With its only port difficult of access, and with no means of internal communication, the trade of Tavoy district has always been small and almost entirely confined to Siam and the Straits Settlements. The principal imports are piece goods and other cotton manufactures, raw silk, tea, crockery, wines and spirits, metals, and provisions. The chief manufactures are salt and earthen pots. The gross revenue of the district in 1885–86 was £20,235 [$98,342.10], of which the land contributed £12,663 [$61,541.18]. Tavoy was handed over to the British at the end of the first Burmese war in 1824. A revolt broke out in 1829, headed by Moung Da, the former governor, which was at once quelled, and since then the district has remained in undisturbed possession of the British.

TAWING. See LEATHER.

TAXATION. With regard to taxes in general Adam Smith lays down four maxims which have been briefly described as the maxims of *equality*, *certainty*, *convenience* and *economy*. The treatment of the general principles of taxation by subsequent writers consists in the main of the development and criticism of these celebrated canons.

Equality.

Equality of Taxation.—The subjoined passage from Adam Smith contains the germs of several distinct theories of what constitutes just or equal taxation:

> "The subjects of every state ought to contribute towards the support of its government as nearly as possible in proportion to their respective abilities, that is, in proportion to the revenue which they respectively enjoy under the protection of the state. The expense of government to the individuals of a great nation is like the expense of management to the joint tenants of a great estate, who are all obliged to contribute in proportion to their respective interests in the estate. In the observation or neglect of this maxim consists what is called the equality or inequality of taxation. Every tax it must be observed once for all, which falls finally upon one only of the three sorts of revenue above-mentioned [viz., rent, wages, profits] is necessarily unequal in so far as it does not affect the other two. In the following examination of different taxes I shall seldom take much further notice of this sort of inequality, but shall in most cases confine my observations to that inequality which is occasioned by a particular tax falling unequally upon that particular sort of private revenue which is affected by it."

The first sentence implies (*a*) that every Government has the *right* to exact contributions for its support from all its subjects. According to this view, the right of taxation is derived directly from the conception of sovereignty. It was the determination to insist on this principle which led to the retention of the 3d. per ℔ duty on tea, that "figment of a tax, that peppercorn rent," which lost the British their American colonies. The Americans opposed to this absolute doctrine the maxim that taxation ought to be coincident with *representation*,—that only those who shared in the powers should have the burdens of government.[1] If the latter opinion is strictly construed it would follow that all taxes on articles of universal consumption are unjust except in a country where all who have the natural have also the legal capacity of voting. The doctrine of sovereignty as the basis of taxation, pushed to its logical extreme, results in the maxim that a Government should impose such taxes as are "most easily assessed and collected, and are at the same time most conducive to the public interests" (M'Culloch). Just as a general looks to the efficiency of his army as a whole, and is prepared to sacrifice any portion if necessary, so, it may be said, the state should not regard the particular interests of individuals, but should rather consider the nation as an organism, or, to adopt older phraseology, a leviathan. So far as the political *existence* of a state is concerned, this view seems to meet with general acquiescence even in modern times, when patriotism is often classed amongst the doubtful virtues, but no ideal of a perfect state has yet met with such acceptance in any nation as to render popular a complete neglect of private interests.

---

[1] [Smith's *Wealth of Nations* appeared in 1776, a year after hostilities began in America, and did not color or contribute to their causes. The contention of the colonies was not an economical but a constitutional question. They acknowledged the *sovereignty* of the *crown*, even in taxation, but asked to have that sovereignty exercised according to the maxims of the British constitution and their own charters, on the ground that subjects of the crown did not forfeit their rights by becoming colonists. They held *parliament not to be sovereign*, except among those whom it represented, and therefore not among colonists who had no voice therein. No theory of indirect taxation is involved in that contest at all, and America is not inconsistent in raising a revenue by a tariff.—AM. ED.]

Accordingly, a second basis of taxation (*b*) is found in the expansion of the term "abilities" used by Adam Smith, which leads to the position that taxes ought to be levied so as to involve *equality of sacrifice* on the part of the contributors. This is the ideal of taxation which was advocated by Mill and Fawcett. "Equality of taxation as a maxim of politics," says the former, "means equality of sacrifice. It means the apportioning the contribution of each person towards the expenses of government, so that he shall feel neither more nor less inconvenience from his share of the payment than every other person experiences from his." It is admitted that this standard cannot be completely realized, but it is thought to furnish a proper foundation of remission in some cases and of proportional increase of taxation in others. It is generally on this ground that it is proposed to leave incomes below a certain amount untaxed,—a plan which, so far as direct taxes are concerned, has been adopted in the United Kingdom. It is clear, however, that any taxes on commodities in general use must infringe this canon, whilst the distinction between "necessaries" and "luxuries," as Adam Smith pointed out, is difficult to draw in communities advancing in civilization; and certainly a considerable portion of the taxes on stimulants is, as a matter of fact, derived from persons whose incomes are below what is generally considered a reasonable minimum for the standard of comfort, and such persons would probably consider enforced abstinence a greater sacrifice than the payment of a direct tax. It is also principally on the ground of equality of sacrifice that the proposal for graduated or progressive taxation rests. It is argued that a person with £10,000 [$48,600] a year can pay 10 per cent. (for example) as easily as a person with £1000 [$4860] can pay 5 per cent. It is to be observed that the principle of equality of sacrifice regards the payment of taxes as duty imposed on the subjects of a state independently of the advantages they may derive individually from the expenditure of the amount levied.

A third basis of taxation, however, is found in the principle (*c*) that taxes ought to be considered as *payment for valuable services* rendered by the state to individuals, and this seems to be the position Adam Smith had in view in introducing the clause "under the protection of the state," and in comparing the individuals of a great nation to the joint tenants of a great estate. It is easy to show, as Mill does, that, if protection is taken in its narrowest signification, as a matter of fact the poor need more protection than the rich, but the argument becomes more plausible, and more consonant with the general teaching of Mill, if stress is laid on the protection and assistance afforded by the state in the process of acquisition of individual fortunes—a view of taxation sometimes called the *social dividend' theory* (*cf.* Walker, Helferich). It is really on this ground that Mill proposes that the "unearned increment" from land should be taken by the state, and, as has often been pointed out "unearned increments" are by no means confined to land. Without much exaggeration the state may be regarded as a partner in all industrial undertakings, and is therefore entitled to a share in the proceeds. In a somewhat similar manner poor rates, education rates, etc., have been regarded as of the nature of insurance paid by the rich against the carelessness of the poor. The principle under consideration has been generally applied in cases in which the service rendered by the state and the benefit accruing to individuals are easily discovered and estimated, especially in connection with local taxation.

The object of taxation is in general to provide the state with an adequate revenue, but in all cases the indirect effects are important, and sometimes provision of revenue is considered of secondary importance. Accordingly it has been maintained (*d*) that the state ought to use its powers of taxation for the promotion of various *social ends*. Adam Smith remarks that "it has for some time past been the policy of Great Britain to discourage the consumption of spirituous liquors, on account of their supposed tendency to ruin the health and corrupt the morals of the common people," and in our own times the falling off in the revenue from alcoholic drinks often furnishes a subject for apparent congratulation in "budget" speeches. German writers with socialistic tendencies (*e.g.*, Wagner) have emphasized this social point of taxation; and Mill, although disapproving of graduated taxation of income, advocated the imposition of extremely heavy succession duties, with the object of promoting a better distribution of national wealth and compelling individuals to rely on themselves. Many nations again have imposed duties on imports with the view of protecting and encouraging home industries, and most of the import duties levied in England before the great reforms of Peel were of this nature. Accordingly, both theoretically and practically, the promotion of social or moral ends may be considered as a fourth basis of taxation. It is worth noticing that in early times the fines received in the courts of justice were an important source of revenue.

Whatever basis of taxation be adopted, the elementary principle of justice noticed in the conclusion of A. Smith's first canon must be considered. If it is just to tax A, it is just to tax B under precisely similar circumstances. Thus stated, the principle seems almost formal, but for practical purposes small differences in circumstances may be neglected, and it is clear that in any great nation the taxpayers may be arranged in a limited number of groups, within each of which the constituent individuals may be regarded as similarly situated. A tax on rent, or wages, or profits would be obviously unequal if those in one place or employment were taxed while those in another were left free. The practical difficulty is to discover what cases may fairly be regarded as similar, especially if equality of sacrifice be taken as the ideal.

As a matter of fact, in every civilized community a complex system of taxation is adopted, the different parts of which rest in different degrees upon the various principles just noticed. Some taxes are justified on the grounds of their convenience to the sovereign power, and others are increased or diminished in certain cases in accordance with the principle of equality of sacrifice; some are regarded as payments for services rendered by the state, others partake of the nature of sumptuary regulations or are approved on various social or moral grounds; and sometimes the imposition of one productive tax involves, on the ground of simple equality, the adoption of similar taxes which are hardly worth collecting.

Certainty.

The remaining canons of Adam Smith are partly, like the first, ethical in character partly purely economic. Of the second—the canon of *certainty*—Adam Smith remarks: "The time of payment, the manner of payment, the quantity to be paid, ought all to be clear and plain to the contributor and to every other person [on the ground of the otherwise arbitrary powers which are given to the tax-gatherer] . . . . The certainty of what each individual ought to pay is in taxation a matter of so great importance that a very considerable degree of inequality, it appears, I believe, from the experience of all nations, is not near so great an evil as a very small degree of uncertainty." Perhaps the best example of the infringement of this canon is furnished by the taxes levied from the miserable provincials by their Roman governors.

Convenience.

The third rule—the canon of *convenience*—which enjoins that "every tax ought to be levied at the time or in the manner to which it is most likely to be convenient for the contributor to pay it," may be justified, not merely on general grounds of good government, but also on the special economic ground of the increase in the productiveness of taxes which satisfy the condition. It has been found possible to raise a considerable revenue by taxes on commodities, the payments of which by the consumers are made in insensible portions, when it would have been impossible to collect the same amount by direct taxation at comparatively long intervals. Taxation is in this respect like bleeding.

Economy.

The fourth rule—the canon of *economy*—states as its general principle that "every tax ought to be so contrived as both to take out and to keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the state." Taxes may, according to Adam Smith, break this rule by requiring a large number of officials for their collection, by restraint of trade and production, by encouraging smuggling, and by causing unnecessary vexation; "and, though vexation is not, strictly speaking, expense, it is certainly equivalent to the expense at which every man would be willing to redeem himself from it." On smuggling Adam Smith elsewhere remarks that "to pretend to have any scruple about buying smuggled goods would in most countries be regarded as one of those pedantic pieces of hypocrisy which serve only to expose the person who affects to practice them to the suspicion of being a greater knave than his neighbors." It may be observed that in practical politics it is generally taken for granted that a tax which can be evaded will be evaded, and indirect methods of taxation are to a great extent devices by which possibilities of evasion are restricted.

Other general principles.

To these general rules of taxation explicitly given by Adam Smith, the following may be added, most of which are implied in different passages of his treatment of taxation, but have been expounded and emphasized by subsequent writers. A convenient summary is given by Helferich in Schönberg's *Handbuch der Politischen Oekonomie* (vol. ii. p. 138). (*a*) A given amount of revenue is, as a rule, both from the point of view of the Government and its subjects, more conveniently raised from a small number of very productive taxes than from a larger number with smaller returns per unit. This was one of the principal financial reforms advocated by Adam Smith with reference to the customs duties, and has been carried out in the United Kingdom by Sir Robert Peel and his successors. The inextricable confusion of the customs duties levied before these reforms were effected can only be realized by those who study the details of the history of taxation. A similar process of simplification has been partially applied to the direct taxes, but in many cases (especially in local taxation) the rule is more honored in the breach than in the observance. (*b*) A good system of taxation ought to provide for a self-acting increase in the revenue in proportion as the population and the consequent demands for governmental expenditure increase. It has been found by experience that an old tax causes less inconvenience than a new tax of smaller amount, a fact which is so striking in some cases as to have given rise to the saying that an old tax is no tax. (*c*) Those taxes are best which yield a steady and calculable return, instead of a return fluctuating in character and difficult to estimate. (*d*) Those taxes are best which in case of need can be most conveniently increased in amount. It is this characteristic of the income tax which renders it so popular with chancellors of the exchequer, and it was partly on this ground that Mr. Gladstone substituted a tax on beer for the tax on malt. (*e*) Regard must always be paid to the real incidence of taxation, and care taken that the real burden of the tax falls on those aimed at by the legislature. No part of the theory or practice of taxation has given rise to so much controversy as the incidence of particular taxes, a subject indeed of so much difficulty and importance as to occupy the greater portion of the treatment by systematic writers.

Direct and indirect taxes.

INCIDENCE OF TAXATION.—Taxes are generally divided into *direct* and *indirect*. A direct tax is defined by Mill as one "demanded from the very persons who it is intended or desired should pay it." Others (*e.g.*, M'Culloch) define it as a tax taken directly from income or capital. In the former definition non-transferable taxes on expenditure would be included (*e.g.*, a tax on livery servants) but not in the latter. Mill's definition has been generally adopted (*e.g.*, by Wagner, in the German *Handbuch*, vol. ii. p. 152); but in any case the most important direct taxes practically are those levied on income or capital directly, and the most important indirect the customs and excise duties. In examining the incidence of taxation the order of arrangement adopted by Adam Smith seems best. He discusses separately taxes on the three great species of income,—rent, profits, and wages (appending to the articles on the first two an examination of taxes upon the capital value of land, houses, and stock), and taxes intended to fall indifferently upon every species of revenue, viz., capitation taxes and taxes upon consumable commodities.

Taxes on rent.

Taxes on Rent.—What is commonly known as rent consists in general of two parts, which may be termed economic rent and profit rent. Economic rent arises from the superiority of advantage of any source in the production of a certain amount of utility over the least productive source which the conditions of demand and supply (including transmission to market) render it possible to employ. Thus, in the production of food, some lands have an advantage in fertility or situation; again, in furnishing amenities of accommodation or facilities for business, some houses have from their situation a similar advantage; and again, different processes in the arts and manufactures are superior to others (giving rise to patents). In all these cases where the amount of the superior sources is limited (naturally or artificially), and recourse must be made to inferior sources of supply, economic rent is paid for the superior advantage. Any tax imposed on this species of revenue falls on the owner. If levied in the first instance from the lessee, he will pay so much less rent, and any new taxes imposed during the currency of leases ought, if intended to fall on the owner, to be taken directly from him. It may be assumed that every owner of a superior source has exacted the highest price obtainable for its use, so that he cannot transfer the tax to the tenant, nor through the tenant to the consumer. If, for example, a tax is imposed on the economic rent of agricultural land, the landlord cannot exact it from the tenant (for if the tenant could afford more rent, why under competition was he not forced to do so before?) nor from the consumer of the produce, for the price is obviously determined independently of rent. Similarly a tax on the ground rent of houses, if it be assumed that the land is useless for other purposes, must fall on the owners; although a certain portion will be transferred to the occupier if the landlord could use it otherwise and escape the tax (*cf.* Mill, bk. v. ch. iii. § 6). Taxes on economic rent of various kinds, so heavy as to absorb the whole amount, have been advocated by some theorists on grounds noticed under Adam Smith's first canon. It is said they would impose no burden on the state as a whole, that they would not affect production or accumulation, and even that the substitution of the state for private owners—who are simply *nati consumere fruges*—would really increase the wealth and power of the nation by compelling these unproductive consumers to work, and by lightening the pressure of taxation on industry. It is, however, obvious that the confiscation of rent would, seeing that land has for generations been in the circle of exchangeable commodities, strike at the roots of the institution of private property. Apart from this general objection, there would in the case of agricultural land be great difficulty in separating economic from profit rent, and any exceptional tax on the latter would obviously tend to check agricultural improvements.

Taxes on profits.

Taxes on Profits.—Profits, as commonly used, is a term embracing three elements which, from an economic and financial point of view, are quite distinct in character, viz., interest (pure and simple), insurance against risk, and earnings of management. The interest on capital in any industrial area, lent on the same security, tends to equality. If, then, a tax is imposed on *interest in every form*, the incidence in the first place will be on the owners of capital. But two indirect consequences will follow. (1) As Adam Smith remarks, "the proprietor of stock is properly a citizen of the world, and is not necessarily attached to any particular country. He would be apt to abandon the country in which he was exposed to a vexatious inquisition in order to be assessed to a burdensome tax, and would remove his stock to some other country, where he could either carry on his business or enjoy his fortune more at his ease." In this case the ultimate result would be that the country in which the tax was imposed would possess less capital, and thus would yield a higher rate of interest sufficient to counterbalance the burden of the tax. (2) The tax would tend to check the accumulation of capital within the country, so far as the interest received is a cause of accumulation, with the same ultimate result as in the former case. It must, however, be observed that the rate of interest is only one of the causes affecting the accumulation of capital.

A tax on some *particular form of interest* (security still being supposed perfect), for example on mortgages on land, would obviously fall on the borrowers. In the same way a tax on that part of the profit rent of houses which is interest on capital tends to fall on the occupier. In general, however, the security is more or less imperfect, and the insurance against risk is allowed for in the rate of interest charged on borrowed capital. Thus a tax which took equal percentages from all species of interest would be in part a tax on insurance against risk, and the tendency must be for such a tax to fall on the borrowers of capital. Suppose at any time a perfect security yields 3 per cent. and one with greater risk 6 per cent., then 3 per cent. represents the estimated value of the insurance against risk. A tax which reduces the net yield on the first to 2 per cent. would reduce the net yield on the latter to 4 per cent. In order, then, for the insurance against risk to remain the same, the rate yielded by the latter must rise from 6 to 7½ per cent. It follows, then, that a tax levied on all forms of interest (no allowance being made for risk) would tend to check investment in proportion as risk was involved, and would thus check industrial enterprise. This result would follow even although the rate of interest on perfect security, owing to the causes mentioned above, were raised in proportion to the tax.

A tax on that part of profits known as earnings of management would, if imposed generally, fall in the first instance on the *entrepreneurs* or employers of capital, and with similar indirect consequences to those just noticed in regard to interest. Capital would tend to flow abroad, and accumulation would be checked, since in general the employers of capital are also to a large extent the owners. So far as profits, in this sense, are of the nature of rent (a view recently advocated as regards all profits by Prof. Walker), a tax on profits would be analogous to a tax on rent. If the differences in the net advantages of different methods of employing capital are supposed to remain constant (according to Prof. Marshall's view of earnings of management), a proportional tax on profits must be in part transferred to the consumers of the articles produced, in the same way as a tax on interest with risk was shown to fall on the borrower. It will be seen from this general survey that the incidence and effects of a tax on profits (taking the term in its common acceptation without analysis) are extremely difficult to determine, and the practical difficulty is still greater than the theoretical. For, as M'Culloch and others have shown, profits are always fluctuating and difficult to estimate. So great, for example, is this difficulty felt to be as regards farmers' profits that in the income tax it is assumed that such profits bear a certain proportion to the rent paid for land on a purely empirical rule, which may happen to hit the mark in a majority of cases, but is much more likely to be unequal and unjust in its operation.

A tax on some particular form of profits (as distinct from a general tax on profits) will, it is generally said, fall on the consumer of the article produced, on the ground of the tendency of profits to equality. This view will be noticed below under taxes on consumable commodities.

Taxes on capital.

Taxes on Capital.—In early English history taxes upon capital of a very simple kind played an important part. A grant, for example, of certain fractional parts of movables, commencing with the famous Saladin tithe (on both rent and movables) in 1188, and gradually settling down to a fifteenth for the counties and a tenth for the towns, prevailed for more than three centuries. In 1334 a fifteenth and tenth was fixed at a certain sum for each township, and after this date a grant of one or more "fifteenths and tenths" meant simply a grant according to the scale then fixed (Dowell, vol. iii. p. 75). But in our own times taxes on capital are levied principally when property changes hands, and may be divided, as they are by Adam Smith, according as they are levied when property passes (*a*) from the dead to the living, (*b*) from the living to the living.

It is obvious, as regards incidence, that taxes of the first class (*a*) are the most direct of all taxes, in the sense that they cannot be transferred to other persons by the beneficiaries. The principal difficulties connected with the "death duties," as they are often called, arise in connection with the canon of equality of taxation. Opinion is still divided on the proportions which ought to be paid by personal and real estate respectively, as well as on the advisability of the taxes being made progressive according to the value of the property, and there are still greater difficulties in connection with life interests in settled property. Mill was strongly in favor of making the death duties very heavy and also graduated. "I conceive," he says (*Pol. Econ.*, bk. v. ch. ii. § 3), "that inheritances and legacies exceeding a certain amount are highly proper subjects for taxation, and that the revenue from these should be made as great as it can be made without giving rise to evasions by donation during life, or concealment of property, such as it would be impossible adequately to check. The principle of graduation, that is, of levying a larger percentage on a larger sum, though its application to general taxation would be in my opinion objectionable, seems to me both just and expedient as applied to legacy and inheritance duties." The principal objections urged against such taxation are, that a stimulus would be given to personal extravagance and a check placed on accumulation, and that in consequence indirect production would be lessened, partly by want of capital and partly by the check placed on production on a large scale. As regards the want of capital, apart from the check placed on saving, there would be a tendency to send it abroad. A heavy tax on large capitals at home will place a premium on investments abroad, in which evasion would be easy. Perhaps, with the present rate of accumulation, the objection may be made light of, as it is by Mill; but the second, if less obvious, is more important. All our great staple manufactures are necessarily conducted on a large scale, and in many respects also large agricultural capitals are most productive. In manufactures, as a rule, the larger the scale of operations the more extended will be the division of labor in production, and the greater the facilities for ready sale in foreign markets. Of all the causes which contribute to our commercial prosperity, perhaps the most important is the large scale on which our operations are conducted. We are able to employ machinery where the foreigner, working on a smaller scale, is obliged to use manual labor. There can be little doubt that graduated taxation, even on the modified form proposed by Mill, would tend to check production on a large scale. Indirectly it might artificially foster joint-stock companies. (*b*) Taxes on the transference of property from the living to the living cannot, as Adam Smith points out, be very easily taken directly, as such transactions for the most part actually are or might be secret. This has led to the invention of stamp and registration duties. The penalty of invalidity attaching to unstamped documents of various kinds has proved a very effective deterrent to evasion. A tax on sales will vary in its incidence according to the nature of the commodity and the degree of competition or monopoly (*cf.* H. Sidgwick's *Principles of Pol. Econ.*, bk. ii. ch. x.). The most important case is that of taxes on the transfer of land. Theoretically it seems that, just as the farmer who takes land on rent offers more or less rent according to the burdens imposed on the land by rates, etc., so the purchaser of land will consider any expenses connected with its acquisition as part of the capital value, and thus any taxes on transfer will really fall on the sellers. If, however, the taxes are imposed in such a way as to fall less heavily on land when sold in larger than in small quantities, it is clear that the tendency will be for the differential portion of the tax at least to fall on the purchaser of a small amount; and practically at present this feature is characteristic of the English system. A tax on the transfer of stocks and shares is generally held to fall on the seller, as in case of repeal he would obtain so much more; but in this case the same considerations apply as in the case of interest noticed above. A curious example of legal evasion is furnished by time-bargains; and the imposition of the tax directly on the contracts of sale, instead of as at present on the actual transfer, has been strongly urged.

Taxes on wages.

Taxes on Wages.—It is clear that the treatment of taxes on wages will depend on the general view taken of the determination of the rate of wages. Adam Smith appears to lay undue stress on the price of provisions, and to think that in most cases taxes on wages must fall on the employer of labor (bk. v. ch. ii. art. iii.). There seems, however, to be no sufficient reason why a tax on labor should be transferred to the employer, except in the case where the wages are really at a minimum below which the supply of efficient labor could not be kept up. Even in this case, as Prof. Walker shows, there would probably be a degradation of labor before the rise in wages was effected. Certainly no practical statesman at the present time would venture to propose a direct tax on wages, under the idea that it would be transferred to the employer. In Germany it was found necessary to abandon the system, owing to the hardship inflicted on the poor. At any rate, in all cases in which the rate of wages is above the "necessary" minimum, a tax on wages must fall on the laborer. A differential tax on some particular species of employment would, unless it partook of the nature of a monopoly, tend to fall on the consumer of the article produced or the person who enjoys the service rendered. In every case, speaking generally, the incidence of the tax will depend on the conditions of the demand and supply of the labor in question, and no further analysis can be given without entering into the general principles governing wages. See WAGES.

Capitation taxes.

Capitation taxes are chiefly of interest historically, as illustrated in England by the poll-taxes imposed at various times. The income tax as at present levied is in reality not a single uniform tax, as might at first sight appear, but a tax on the various species of rent, interest, profits, and wages. The anomalies which arise from practically taking income as uniform have often been pointed out and acknowledged, but the authority of Mr. Gladstone may be quoted in support of the view that the practical difficulties in the way of a readjustment more in accordance with theoretical principles are insuperable. The objections noted above to a graduated property tax apply, *mutatis mutandis*, to a graduated income tax, which appears, however, to find increasing favor on the Continent. A full discussion of the anomalies of the income tax would involve a repetition of the analysis of the taxes on the various species of income.

Taxes on consumable commodities.

Taxes on Commodities.—The general principles applicable in this case are that, where production takes place under free competition, the tax will, owing to the tendency of profits to equality, be transferred to the consumer, but that, when the article is practically monopolized, a tax must fall on the monopolist, on the assumption that he has already fixed such a price for the article as will, considering the law of demand and the expenses of production, yield him a maximum revenue. The practical difficulties connected with the assumption of equality of profits have been well exposed by Cliffe Leslie (*Financial Reform: Cobden Club Essays*, 2d series, 1871–72).

The incidence of export and import duties is peculiarly difficult to ascertain even theoretically. The prevailing opinion that an import duty necessarily falls on the consumer of the import necessarily involves as its counterpart the position that an export duty must fall on the consumer of the export. If the latter view is upheld it is curious that export duties find such little favor with practical statesmen. It is clear, however, that the real incidence of export and import duties will depend partly on the conditions of production in various countries, partly on the variations in demand due to changes in price, partly on the indirect influence on the general balance of trade, and partly on the possibility of using substitutes for the article taxed (*cf.* H. Sidgwick's *Principles of Pol. Econ.*, bk. iii. ch. v.; Cournot, *Revue Sommaire des Doctrines Économiques*, sects. 5 and 6). A fuller examination is not possible in the limits assigned to this article. In conclusion, it may be pointed out that a thorough investigation of the general principles of taxation must presuppose the principles of political philosophy, whilst a full inquiry into the incidence of particular species of taxes must presuppose the principles of political economy.

(J. S. N†.)

TAXIDERMY, the art of preserving the integument, together with the scales, feathers, or fur, of animals. Little is known of the beginnings of the practice of the "stuffing" or "setting up" of animals for ornament or for scientific purposes; and it is highly probable, from what we gather from old works of travel or natural history, that the art is not more than some three hundred years old. It was practiced in England towards the end of the 17th century, as is proved by the Sloane collection, which in 1725 formed the nucleus of the collection of natural history now lodged in the galleries at South Kensington.

It was not until the middle of last century that any treatise devoted to the principles of the then little understood art was published in France, Réaumur's treatise (1749) being probably the first. This was followed at intervals by others in France and Germany, until the beginning of the present century, when the English began to move in the matter, and several works were published, notably those by E. Donovan,[1] W. Swainson,[2] Capt. Thomas Brown,[3] and others. These works, however, are now inadequate; and since the Great Exhibition of 1851, when the Germans and French taught British taxidermists the rudiments of scientific treatment of natural objects, several works have appeared upon the subject from the pens of

American and English authors, such as J. H. Batty,[1] R. Ward,[2] and Montagu Browne.[3]

The first principle governing the art is that, after the specimen has been procured, in as fresh and clean a state as may be, it should have the skin stripped from the body in such a manner as not to disturb the scales if a fish or a reptile, the feathers if a bird, or the fur or hair if a mammal. To do this correctly requires a small stock of tools, as well as a great amount of patience and perseverance. The appliances comprise several sharp knives (some pointed and some obtuse), a pair of scissors, a pair of pliers, a pair of nippers or "cutting-pliers," some tow, wadding, needles and thread, also a "stuffing-iron," some crooked awls, a pair of fine long flat-nosed pliers, and a camel-hair brush. The preservative compound is often the original (Bécœur's) "arsenical soap," made by cutting up and boiling 2 ℔ of white soap, to which 12 oz. of salt of tartar and 4 oz. of powdered lime (or whiting) are added when dissolved; to this mixture, when nearly cold, 2 ℔ of powdered arsenic and 5 oz. of camphor (the latter previously triturated in a mortar with spirits of wine) are added. The mixture is put away in small jars or pots for use. Like all arsenical preparations, this is exceedingly dangerous in the hands of unskilled persons, often causing shortness of breath, sores, brittleness of the nails, and other symptoms; and, as arsenic is really no protection against the attacks of insects, an efficient substitute has been invented by Browne, composed of 1 ℔ of white curd soap and 3 ℔ of whiting boiled together, to which is added, whilst hot, 1½ oz. of chloride of lime, and, when cold, 1 oz. of tincture of musk. This mixture is perfectly safe to use when cold (although when hot the fumes should not be inhaled, owing to the chlorine given off), and is spoken of as doing its work efficiently. Solutions of corrosive sublimate, often recommended, are, even if efficient, dangerous in the extreme. Powders consisting of tannin, pepper, camphor, and burnt alum are sometimes used for "making skins," but they dry them too rapidly for the purposes of "mounting." Mammals are best preserved by a mixture of 1 ℔ of burnt alum to ¼ ℔ of saltpetre; this, when intimately mixed, should be well rubbed into the skin. Fishes and reptiles, when not cast and modelled, are best preserved in rectified spirits of wine; but this, when economy is desired, can be replaced by "Möller's solution" (bichromate of potash 2 oz., sulphate of soda 1 oz., distilled water 3 pints) or by a nearly saturated solution of chloride of zinc. The cleaning of feathers and furs is performed by rubbing them lightly with wadding soaked in benzoline, afterwards dusting on plaster of Paris, which is beaten out, when dry, with a bunch of feathers.

The preparation and mounting of bird specimens, the objects most usually selected by the amateur, are performed in the following manner. The specimen to be operated upon should have its nostrils and throat closed by plugs of cotton wool or tow; both wing-bones should be broken close to the body, and the bird laid upon a table on its back; and, as birds—especially white-breasted ones—should seldom, if ever, be opened on the breast, an incision should be made in the skin under the wing on the side most damaged, from which the thigh protrudes when pushed up slightly; this is cut through at its junction with the body, when the knife is gently used to separate the skin from this, until the wing-bone is seen on the open side. This is then cut through by scissors, and by careful manipulation the skin is further freed from the back and breast until the neck can be cut off. The other side now remains to be dealt with; from this the wing is cut by travelling downwards, the remaining leg is cut away, and very careful skinning over the stomach and upon the lower back brings the operator to the tail, which is cut off, leaving a small portion of the bone (the coccyx) in the skin. The body now falls off, and nothing remains in the skin but the neck and head. To skin these out properly without unduly stretching the integument, is a task trying to the patience, but it can be accomplished by gradually working the skin away from the back of the head forward, taking care to avoid cutting the eyes or the eyelids, but, by cautious management, to cut the membranous skin over those parts, so that the eyes are easily extracted from the orbits without bursting. The skin should be freed down nearly to the beak, and then the back of the head, with neck attached, should be cut off, the brains extracted, all the flesh cleared from the skull and from the bones of the wings, legs, and tail, the skin painted with the preservative, and ultimately turned into its proper position. When "skins" only are to be made for the cabinet, it is sufficient to fill the head and neck with chopped tow, the body with a false one made of tow, lightly packed or loose according to the genius of the preparer, to sew up the skin of the stomach, and to place a band of paper lightly pinned around the body over the breast and wings, and allow it to remain in a warm position, free from dust, for several days or weeks, according to the size of the specimen. It should then be labelled with name, sex, locality, and date, and put away with insect powder around it.

When, however, the specimen is to be "mounted," the operations should be carried up to the point of returning the skin, and then a false body of tightly wrapped tow is made upon a wire pointed at its upper end. This is inserted through the incision under the wing, the pointed end going up the neck and through the skull to the outside. When the imitation body rests within the skin, pointed wires are thrust through the soles of the feet, up the skin of the back of the legs, and are finally clenched in the body. Wires are also thrust into the butts of the wings, following the skin of the under surface, and also clenched through into the body. A stand or perch is provided, and the bird, being fixed upon this, is, after the eyes have been inserted, arranged in the most natural attitude which the skill of the taxidermist can give it.

Mammals are cut along the stomach from nearly the middle to the breast, and are skinned by working out the hind legs first, cutting them off under the skin at the junction of the femur with the tibia, and carefully stripping the skin off the lower back and front until the tail is reached, the flesh and bones of which are pulled out of the skin, leaving the operator free to follow on up the back and chest until the forelegs are reached, which are cut off in like manner. The neck and head are skinned out down to the inner edges of the lips and nose, great care being exercised not to cut the outer portions of the ears, the eyelids, the nose, or the lips. The flesh being cleared off, and the brain and eyes extracted, the skull should adhere to the skin by the inner edges of the lips. All the flesh should be trimmed from the bones of the legs. The head, being shaped, where the flesh was removed, by tow and clay, is returned into the skin. A long wire of sufficient strength is tightly bound with tow, making a long, narrow body, through which wires are thrust by the skin of the soles of the feet. The leg wires and bones being wrapped with tow and clay into shape, the points of the wires are pushed through the tow body and clenched. They and the body are then bent into the desired position, and modelled up by the addition of more tow and clay, until the contours of the natural body, are imitated, when the stomach is sewn up. A board is provided upon which to fix the specimen, artificial eyes are inserted, the lips, nose, and eyelids fixed by means of pins or "needle-points," and the specimen is then placed in a warm situation to dry.

Reptiles, when small, have their skin removed by cutting away the attachment of the skull to the cervical vertebræ, and by turning the decapitated trunk out at the mouth by delicate manipulation. When large, they are cut along their median line, and treated in the same manner as mammals.

Fishes, after being covered on their best side with paper or muslin to protect the scales, are cut along the other side from the tail to the gills, and are skinned out by removing "cutlets," as large as is possible without cracking the skin, which, indeed, should be kept damp during work. After being cured with a preservative, they are filled with sawdust or dry plaster of Paris, sewn up, turned over on a board, the fins pinned out, and the mouth adjusted, and, when perfectly dry, the plaster may be shaken out.

A new school of taxidermists, with new methods, whose aim is to combine knowledge of anatomy and modelling with taxidermic technique, are now coming to the front, and the next generation will discard all processes of "stuffing" in favor of modelling. Within the limits of an article like the present it is impossible to do more than glance at the intricate processes involved in this. In the case of mammals, after the skin has been completely removed, even to the toes, a copy is made of the body, posed as in life, and from this an accurate representation of form, including delineation of muscles, etc., is built up in light materials; the model is then covered with the skin, which is damped, and pinned in to follow every depression and prominence; the study is then suffered to dry; and, models having been made, in the case of large animals, of the mucous membrane of the jaws, palate, tongue, and lips, these are truthfully reproduced in a plastic material. The ordinary glass eyes are discarded, and hollow globes, specially made, are hand-painted from nature, and are fixed in the head so as to convey the exact expression which the pose of the body demands. Birds, if of any size, can be modelled in like manner, and fishes are treated by a nearly identical process, being finally colored as in a "still-life" painting.

To give a life-like representation, attention is also paid to artistic "mounting." By this is meant the surrounding of specimens with appropriate accessories, and it is well exemplified by the new work shown in the natural history museum at South Kensington, where, for example, birds are arranged as in a state of nature, feeding or flying to their young, sitting on their eggs, swimming in miniature pools, or preening their feathers whilst perched lovingly side by side, and surrounded by exquisitely modelled foliage and flowers. This, with correct modelling of the specimens, which, except in rare instances, is not quite so striking in the new groups, indicates the future of the art, the hope of which lies in the better education of taxidermists as designers, artists, and modellers. (M. B.)

TAXILA. See RAWAL PINDI.

TAY, THE, the longest river in Scotland, has its source on the northern side of Ben Lui, on the borders of Argyllshire and Perthshire, being known in its earlier course as the Fillan, and, after forming Loch Dochart, as the Dochart, until entering Loch Tay, 25 miles from its source, at an elevation above sea-level of 553 feet. Its course through Perthshire is described in the article on that county. Its total length to the town of Perth is about 95 miles, and it drains a total area of about 2400 square miles, while its estuary extends for about other 25 miles. The navigation of the estuary is somewhat impeded by sandbanks. The only important port is Dundee, but vessels of 100 tons can pass up to Perth, the river being tidal to 2 miles above it. The salmon fisheries on the river and its estuary are among the most valuable in Scotland. A railway bridge over the Tay at Dundee, designed by Sir Thomas Bouch (see BRIDGES, vol. iv. p. 306–7), was opened for traffic 31st May, 1878, but was blown down during the crossing of a passenger train 28th December, 1879. Some distance to the west a new bridge, designed by W. H. Barlow, was commenced in 1882, and was opened for general traffic 20th June, 1887.

TAYLOR, BAYARD (1825–1878), one of the most prolific among American authors, was born at Kennett Square in Chester county, Pennsylvania, on 11th January, 1825. The son of a well-to-do farmer, he received his early instruction in an academy at West Chester, and, later, at Unionville. At the age of seventeen he was apprenticed to a printer in West Chester. A little volume, published in 1844 under the title *Ximena, or the Battle of the Sierra Morena, and other Poems*, brought its author a little cash; and indirectly it did him better service as the means of his introduction to *The New York Tribune*. With the money thus obtained, and with an advance made to him on account of some journalistic work to be done in Europe, "J. B. Taylor" (as he had up to this time signed himself, though he bore no other Christian name than Bayard) set sail for the East. The young poet spent a happy time in roaming through certain districts of England, France, Germany, and Italy; that he was a born traveller is evident from the fact that this pedestrian tour of almost two years cost him only £100 [$486]. The graphic accounts which he sent from Europe to *The New York Tribune*, *The Saturday Evening Post*, and *The United States Gazette* were so highly appreciated that on Taylor's return to America he was advised to throw his articles into book form. In 1846, accordingly, appeared his *Views Afoot, or Europe seen with Knapsack and Staff*. This pleasant book had considerable popularity, and its author now found himself a recognized man of letters; moreover, Horace Greeley, then editor of the *Tribune*, placed Taylor on the staff of that journal, thus securing him a certain if a moderate income. His next journey, made when the gold-fever was at its height, was to California, as correspondent for the *Tribune;* from this expedition he returned by way of Mexico, and, seeing his opportunity, published (1850) a highly successful book of travels, entitled *Eldorado, or Adventures in the Path of Empire*. Ten thousand copies were said to have been sold in America, and thirty thousand in Great Britain, within a fortnight from the date of issue. Bayard Taylor always considered himself native to the East, and it was with great delight that in 1851 he found himself on the banks of the Nile. He ascended as far as 12° 30′ N. lat., and stored his memory with countless sights and delights, to many of which he afterwards gave expression in metrical form. From England, towards the end of 1852, he sailed for Calcutta, proceeding thence to China, where he joined the expedition of Commodore Perry to Japan. The results of these journeys (besides his poetical memorials, to which reference will be afterwards made) were *A Journey to Central Africa, or Life and Landscapes from Egypt to the Negro Kingdoms of the Nile* (1854); *The Land of the Saracens, or Pictures of Palestine, Asia Minor, Sicily, and Spain* (1854); and *A Visit to India, China, and Japan in the Year* 1853 (1855). On his return (1854) from these various journeyings he entered, with marked success, upon the career of a public lecturer, delivering addresses in every town of importance from Maine to Wisconsin. After two years' experience of this lucrative profession, he again started on his travels, on this occasion for northern Europe, his special object being the study of Swedish life, language, and literature. The most noteworthy result was the long narrative poem *Lars*, but his "Swedish Letters" to the *Tribune* were also republished, under the title *Northern Travel* (1857). In October, 1857, he married Maria Hansen,[1] the daughter of the well known German astronomer. The ensuing winter was spent in Greece. In 1859 Taylor once more traversed the whole extent of the western American gold region, the primary cause of the journey lying in an invitation to lecture at San Francisco. About three years later he entered the diplomatic service as secretary of legation at St. Petersburg, and the following year (1863) became chargé d'affaires at the Russian capital. In 1863 he returned to the United States and resumed his active literary labors, and it was at this period that *Hannah Thurston*, the first of his four novels, was published. This book had a moderate success, but neither in it nor in its successors did Bayard Taylor betray any special talent as a novelist; some of his characters are faithful studies from life, and he could describe well the aspects of nature,—but a good deal more than this is necessary for the creation of noteworthy romances. In 1874 he went to Iceland, to take part in the centennial celebration which was held in that year. In June, 1878, he was accredited United States minister at Berlin. Notwithstanding the resistless passion for travel which had always possessed him, Bayard Taylor was (when not actually *en route*) sedentary in his habits, especially in the later years of his life; and at Berlin he aggravated a constitutional liver affection by too sedulous devotion to literary studies and pursuits, in the intervals of leisure from his diplo-

---

[1] [In October, 1850, he had married Mary Agnew, a sweetheart of his youth, who survived only two months.—AM. ED.]

matic duties. His death occurred on the 19th of December, only a few months after his arrival in Berlin.

The main drawback to the widespread acceptance of Bayard Taylor's poetry as a whole is its perpetual diffuseness. His most ambitious productions—his *Masque of the Gods* (1872), *Prince Deukalion* (1877), *The Picture of St. John* (1865), *Lars* (1873), and *The Prophet* (1874)—are marred by a ceaseless effort to overstrain his power. *Lars* is the least likely of his longer poems to survive any length of time; it lacks the grandiose eloquence and impressive "adjuncts" of the *Masque* or *Prince Deukalion*, while in theme and treatment it is, at most, only sedately agreeable. *The Poems of the Orient* contains his most genuinely satisfactory poetic writings. But probably long after even the most familiar of the poems just mentioned have ceased to be popular, when even the *Views Afoot* and *Eldorado* no longer hold the attention of the numerous public interested in vividly narrated experiences of travel, Bayard Taylor will be remembered by his poetic and excellent translation of *Faust*. Taylor felt, in all truth, "the torment and the ecstasy of verse"; but, as a critical friend has written of him, "his nature was so ardent, so full-blooded, that slight and common sensations intoxicated him, and he estimated their effect, and his power to transmit it to others, beyond the true value." He felt life as perhaps only the poetic temperament can experience the beauty of the world; single words thus became for him so charged with poetry that he overlooked the fact that to most people these were, simply in themselves, mere abstract terms—sunshine, sea, spring, morning, night, and so forth. Thus a stanza having absolutely nothing original or striking or even poetic in it would, because born of him, seem to be poetry unadulterated; to *his* mind, each line, each word, was charged with delightful significance, therefore—so he felt—would be so also to the sympathetic reader. He had, from the earliest period at which he began to compose, a distinct lyrical faculty; so keen indeed was his ear that he became too insistently haunted by the music of others, pre-eminently of Tennyson. But he had often a true and fine note of his own. His best short poems are "The Metempsychosis of the Pine" and the well-known Bedouin love-song, the latter a stirring lyric that ought assuredly to endure. In his critical essays Bayard Taylor had himself in no inconsiderable degree what he wrote of as "that pure poetic insight which is the vital spirit of criticism." The most valuable of these prose dissertations are the *Studies in German Literature*.

[The translation of Goethe's *Faust* with copious annotations and a close rendering of German into English metres, of which the first part appeared in 1870 and the second in 1871, is Taylor's greatest work, for which he passed years of preparation.]

[Works of Bayard Taylor not mentioned above are, besides some encyclopædic books, *Rhymes of Travel* (1851), *American Legend*, a Harvard Phi Beta Kappa poem (1850), *Book of Romances, Lyrics, and Songs* (1851), *Poems of Home and Travel* (1855), *Poet's Journal* (1862), *John Godfrey's Fortunes* (1864), *Story of Kennett* (1866), *Colorado*, a Summer Trip (1867), *Ballad of Abraham Lincoln* (1869), *Joseph and his Friends*, a novel (1870), *The Prophet*, a tragedy (1874), *Home Pastorals and Lyrics* (1875), *Echo Club* (1876), *Boys of Other Countries* (1876).

His *Life and Letters*, by his widow and Horace E. Scudder (2 vols., 1884), gives a true picture of the man.

His youngest brother, FREDERICK TAYLOR (1840–63), was taken to Europe by Bayard in 1856; studied at the University of Michigan; at the outbreak of the civil war raised a company; was taken prisoner at Harrisonburg, Va.; became colonel; led a charge at Fredericksburg where he was twice wounded, again led a charge at the Round Top, Gettysburg, and fell in the front rank. He is nobly commemorated in a letter of Bayard Taylor to his mother, on page 413, vol. i. of the *Life and Letters*.—AM. ED.]

TAYLOR, BROOK (1685–1731), a distinguished mathematician of Newton's school, was the son of John Taylor, of Bifrons House, Kent, by Olivia, daughter of Sir Nicholas Tempest, Bart., of Durham, and was born at Edmonton in Middlesex, August 18, 1685. He entered St. John's College, Cambridge, as a fellow-commoner in 1701, and took degrees of LL.B. and LL.D. respectively in 1709 and 1714. Having studied mathematics with applause under Machin and Keill, he obtained in 1708 a remarkable solution of the problem of the "centre of oscillation," which, however, remaining unpublished until May, 1713 (*Phil. Trans.*, vol. xxviii. p. 11), his claim to priority was unjustly disputed by John Bernoulli. Taylor's *Methodus Incrementorum Directa et Inversa* (London, 1715) added a new branch to the higher mathematics, now designated the "calculus of finite differences." Among other ingenious applications, he used it to determine the form of movement of a vibrating string, by him first successfully reduced to mechanical principles. The same work contained (p. 23) the celebrated formula known as "Taylor's theorem." It is of extensive use in almost every analytical inquiry; but its full importance remained unrecognized until pointed out in 1772 (Berlin *Memoirs*) by Lagrange, who later termed it "le principal fondement du calcul différentiel."

In his essay on *Linear Perspective* (London, 1715), Taylor set forth the true principles of the art with much originality, and in a more general form than any of his predecessors. The little work suffered, however, from the brevity and obscurity which affected most of his writings, and needed the elucidation bestowed on it in the treatises of Joshua Kirby (1754)[1] and Daniel Fournier (1761).

Taylor was elected a fellow of the Royal Society early in 1712, sat in the same year on the committee for adjudicating the claims of Newton and Leibnitz, and acted as secretary to the society January 13, 1714, to October 21, 1718. During a visit to Paris in 1716, he made acquaintance with Bossuet and the Comte de Caylus, and knit a warm friendship with Bolingbroke, whom he visited at La Source in 1720. From 1715 his studies took a philosophical and religious bent. He corresponded, in that year, with the Comte de Montmort on the subject of Malebranche's tenets; and unfinished treatises, "On the Jewish Sacrifices" and "On the Lawfulness of Eating Blood," written on his return from Aix-la-Chapelle in 1719, were afterwards found among his papers. His marriage in 1721 with Miss Brydges of Wallington, Surrey, led to an estrangement from his father, a person of somewhat morose temper, which terminated in 1723 after the death of the lady in giving birth to a son. The ensuing two years were spent by him with his family at Bifrons, and in 1725 he married, with the paternal approbation, Sabetta, daughter of Mr. Sawbridge of Olantigh, Kent, who, by a strange fatality, died also in childbed in 1730; in this case, however, the infant, a daughter, survived. Weighed down by repeated sorrows, Taylor's fragile health gave way; he fell into a decline, died December 29, 1731, at Somerset House, and was buried at St. Ann's, Soho. By his father's death in 1729 he had inherited the Bifrons estate. Socially as well as intellectually gifted, he possessed a handsome person and engaging manners, and was accomplished to an uncommon degree in music and painting. As a mathematician, he was the only Englishman after Newton and Cotes capable of holding his own with the Bernoullis; but a great part of the effect of his demonstrations was lost through his failure to express his ideas fully and clearly.

A posthumous work entitled *Contemplatio Philosophica* was printed for private circulation in 1793 by his grandson, Sir William Young, Bart., prefaced by a life of the author, and with an appendix containing letters addressed to him by Bolingbroke, Bossuet, etc. Several short papers by him were published in *Phil. Trans.*, vols. xxvii. to xxxii., including accounts of some interesting experiments in magnetism and capillary attraction. He issued in 1719 an improved version of his work on perspective, with the title *New Principles of Linear Perspective*, revised by Colson in 1719, and printed again, with portrait and life of the author, in 1811. A French translation appeared in 1753 at Lyons. Taylor gave (*Methodus Incrementorum*, p. 108) the first satisfactory investigation of astronomical refraction.

See Watt, *Bibliotheca Britannica*; Hutton, *Phil. and Math. Dictionary*; Fétis, *Biog. des Musiciens*; Th. Thomson, *Hist. of the R. Society*, p. 302; Grant, *Hist. Phys. Astronomy*, p. 377; Marie, *Hist. des Sciences*, vii. p. 231.

TAYLOR, SIR HENRY (1800–1886), poet and colonial statesman, was born October 18, 1800, at Bishop-Middleham, in the county of Durham. His ancestors had been small landowners for some generations, and both his studious father, who late in life emerged for a time from a recluse existence to make an efficient secretary to the Poor Law Commission, and his original warm-hearted mother were interesting persons. His mother died while he was yet an infant, and he was chiefly educated by his father, who, finding him less quick and deeming him less intelligent than his two elder brothers, allowed him to go to sea as a midshipman. Eight months summed up his naval career; it had taken much less to disgust him with it. After obtaining his discharge he was appointed to a clerkship in the storekeeper's office, and had scarcely entered upon his duties ere he was attacked by typhus fever, which carried off both his brothers, then living with him in London. In three or four years more his office was abolished while he was on duty in the West Indies. On his return he found his father happily married to a lady whose interest and sympathy proved of priceless value to him. Through her he became acquainted with her cousin Isabella Fenwick, the neighbor and intimate friend of Wordsworth, who introduced him to Wordsworth and Southey. Under these influences he lost his early admiration for Byron, whose school, whatever its merits, he at least was in no way calculated to adorn, and his intellectual powers developed rapidly. In October, 1822, an article from his pen on Moore's *Irish Melodies* appeared in the *Quarterly Review.* A year later he departed for London to seek his fortune as a man of letters, and met with such rapid success, though not precisely in this capacity, as has but rarely attended an unknown young man. He became editor of the *London Magazine*, to which he had already contributed, and in January, 1824, obtained, through the influence of Sir Henry Holland, an appointment in the Colonial Office, insuring him, not only an ample salary, but considerable influence in this department of public affairs. The general standard of the office was probably at that time low; at all events Taylor was immediately entrusted with the preparation of confidential state papers, and his opinion soon exercised an important influence on the decisions of the secretary of state. He visited Wordsworth and Southey, travelled on the Continent with the latter, and at the same time, mainly through his friend and official colleague, the Hon. Hyde Villiers, became intimate with a very different set, the younger followers of Bentham, without, however, adopting their opinions,—"young men," he afterwards reminded Stuart Mill, "who every one said would be ruined by their independence, but who ended by obtaining all their hearts' desires, except one who fell by the way." The reference is to Hyde Villiers, who died prematurely, and for whose sister, afterwards Lady Theresa Lewis, Taylor was an unsuccessful suitor. He actively promoted the emancipation of the slaves in 1833, and became an intimate ally of Sir James Stephen, then counsel to the Colonial Office, afterwards under-secretary, by whom the Act of Emancipation was principally framed. His first drama, *Isaac Comnenus*, was published anonymously in 1827. Though highly praised by Southey, it made little impression on the public. *Philip van Artevelde*, the subject of which had been recommended to him by Southey, was begun in 1828, published in 1834, and, aided by a laudatory criticism from Lockhart's pen, achieved extraordinary success. *Edwin the Fair* (1842) was less warmly received. In the interim he had married (1839) the daughter of his former chief Lord Monteagle, and, in conjunction with Stephen, had taken a leading part in the abolition of negro apprenticeship in the West Indies. *The Statesman*, a volume of essays suggested by his official position, had been published in 1836, and about the same time he had written in the *Quarterly* the friendly advertisements of Wordsworth and Southey, subsequently published under the somewhat misleading title of *Notes from Books*. In 1847 he was offered the under-secretaryship of state, which he declined. *Notes from Life* and the *The Eve of the Conquest* appeared in this year, and *Notes from Books* in 1849. An experiment in romantic comedy, *The Virgin Widow*, afterwards entitled *A Sicilian Summer*, was published in 1850. "The pleasantest play I had written," says the author; "and I never could tell why people would not be pleased with it." His last dramatic work was *St. Clement's Eve*, published in 1862. In 1869 he was made K.C.M.G. He retired from the Colonial Office in 1872, though continuing to be consulted by Government. His last days were spent at Bournemouth in the enjoyment of universal respect; and the public, to whom he had hitherto been an almost impersonal existence, became familiarized with the extreme picturesqueness of his appearance in old age, as represented in the photographs of his friend Mrs. Cameron. He died on March 27, 1886.

---

[1] [This "little work" is not that of 1719 which is more elaborate, and Kirby's book is not an elucidation but a new treatise founded on Taylor's work and bearing his name.—AM. ED.]

Sir Henry Taylor is pre-eminently the statesman among English poets. When he can speak poetically in this character he is impressive, almost great; when he deals with the more prosaic aspects of policy, he is dignified and weighty, without being altogether a poet; when his theme is entirely unrelated to the conduct of public affairs or private life he is usually little more than an accomplished man of letters. An exception must be made for the interesting character of Elena in *Philip van Artevelde*, and for Artevelde's early love experience, which reproduces and transfigures the writer's own. The circumstance of *Philip van Artevelde* being to a great extent the vehicle of his own ideas and feeling explains its great superiority to his other works. It is subjective as well as objective, and to a certain extent lyrical in feeling, though not in form. Though more elaborate than any of his other dramas, it seems to smell less of the lamp. He has thoroughly identified himself with his hero, and the only fault to be found with this noble picture of a consummate leader and statesman is the absence of the shadow required for a tragic portrait. The blame allotted to Artevelde is felt to be merely conventional, and the delineation of uniform excellence becomes monotonous. The hero of *Edwin the Fair*, Dunstan the ecclesiastical statesman, the man of two worlds, is less sympathetic to the author and less attractive to the reader. The character is nevertheless a fine psychological study, and the play is full of historical if not of dramatic interest. *Isaac Comnenus* is more Elizabethan in tone than his other dramas. Comnenus is like a preliminary sketch for Van Artevelde: and the picture of the Byzantine court, and people is exceedingly lively. The idea of the revival of romantic comedy in *The Virgin Widow* is excellent, but the play lacks the humor which might have made it a success. The length of the speeches, even when not set speeches, is a drawback to all these dramas. Taylor's lyrical work is in general laboriously artificial. It is therefore extraordinary that he should have produced two songs ("Quoth tongue of neither maid nor wife" and "If I had the wings of a dove") which it would hardly be an exaggeration to call worthy of Shakespeare. His character as an essayist repeats his character as a dramatist. The essays published under the title of *The Statesman* occupy a peculiar place in literature. They have serious faults, especially the too obvious imitation of Bacon, but they nevertheless are original in their point of view, and their wisdom is the result of a different kind of observation from that which qualifies the bulk of essayists on human life. When writing as one of these Taylor is less removed from the commonplace, though many of his remarks are admirable. As a literary critic he seems unable to get beyond Wordsworth and the select circle of poets admired by the latter. His essays on Wordsworth did much to dispel the conventional prejudices of the day, but will not advance the study of the poet where his greatness is already recognized. His strictures on Byron and Shelley are narrow and not a little presumptuous. Presumption, indeed, the last fault to have been expected in so grave and measured a writer, is one of those of which he most freely accuses himself in the autobiography published a year before his death. It is not otherwise apparent in this highly interesting book, which, sinning a little by the egotism pardonable in a poet and the garrulity natural to a veteran, is in the main a pleasing and faithful picture of an aspiring youth, an active maturity, and a happy and honored old age. (R. G.)

TAYLOR, Isaac (1787–1865), a voluminous writer on philosophical and theological subjects, was born at Lavenham, Suffolk, in 1787, and was trained by his father to be an artist, but early adopted literature as a profession. From 1824, the year of his marriage, he lived a busy but uneventful life at Ongar, in the parish of Stanford Rivers, Essex, where he died on June 28, 1865.

He early became a contributor to the *Eclectic Review*, when it was conducted by Robert Hall and John Foster, and in 1822 he published a small volume entitled *Elements of Thought*. This was followed by a translation of Theophrastus with original etchings, a *History of the Transmission of Ancient Books to Modern Times, Memoirs and Correspondence of Jane Taylor* (his sister, who died in 1824), and a translation of Herodotus. None of these works attained very great popularity; but in 1829 he published anonymously a work bearing upon the religious and political problems of the day, entitled *The Natural History of Enthusiasm*, which was eagerly read and speedily ran through eight or nine editions. The success of this publication encouraged him to produce, also anonymously, *The Natural History of Fanaticism, Spiritual Despotism, Saturday Evening*, and *The Physical Theory of Another Life*, all of which commanded a large circulation. Among his subsequent works may be mentioned *Ancient Christianity*, a series of dissertations in reply to the "Tracts for the Times," a volume entitled *The Restoration of Belief*, and a course of lectures on *The Spirit of Hebrew Poetry*.

TAYLOR, JEREMY (1613–1667), was a native of Cambridge, and was baptized on the 15th August, 1613. His father, Nathaniel, though a barber, was a man of some education, respected by his townsmen, and lineally descended from Dr. Rowland Taylor, Cranmer's chaplain, who suffered martyrdom under Mary. Jeremy, after passing through the grammar school, was entered at Caius College as a sizar in 1626, eighteen months after Milton had entered Christ's, and while George Herbert was public orator and Edmund Waller and Thomas Fuller were undergraduates of the university. He was elected a fellow of his college in 1633, but the best evidence of his diligence as a student is the enormous learning of which he showed so easy a command in after years. Accepting the invitation of Risden, a fellow-student, to supply his place for a short time as lecturer in St. Paul's, he at once attracted attention by his remarkable eloquence as well as by his handsome face and youthful appearance. Archbishop Laud, ever on the outlook for men of capacity, sent for Taylor to preach before him at Lambeth, and, discerning that his genius was worth fostering, dismissed him from the overpressure of the metropolis to the quiet of a fellowship in All Souls, Oxford, and at the same time, by making him one of his own chaplains, showed his desire to keep him in permanent connection with himself. At Oxford Chillingworth was then busy with his great work, the *Religion of Protestants*, and it is possible that by intercourse with him Taylor's mind may have been turned towards the liberal movement of his age. After two years in Oxford, in March, 1638, he was presented by Juxon, bishop of London, to the rectory of Uppingham, in Rutlandshire. In the autumn of the same year he was appointed to preach in St. Mary's on the anniversary of the Gunpowder Plot, and apparently used the occasion to clear himself of a suspicion, which, however, haunted him through life, of a secret leaning to the Romish communion. This suspicion seems to have arisen chiefly from his intimacy with Christopher Davenport, better known as Francis a Sancta Clara, a learned Franciscan friar who became chaplain to Queen Henrietta; but it may have been strengthened by his known connection with Laud, as well as by his ascetic habits and ritualistic propensities. More serious consequences followed his attachment to the Royalist cause, when in 1642 the livings of the loyal clergy were sequestered by decree of parliament. The author of *Episcopacy Asserted against the Aerians and Acephali New and Old*, ineffective as that work seems in the light of modern research, could scarcely hope to retain his parish. Along with Fuller, Chillingworth, and others, he found temporary refuge with the king at Oxford. His two little boys must have been cared for by friends, for his wife, Phœbe Langsdale, whom he had married the year after his settlement at Uppingham, had died with her third child in that disastrous year 1642.

During the next fifteen years Taylor's movements are not easily traced. Sometimes he appears with the king, from whom at his last interview he received, in token of his regard, his watch and some jewels which had ornamented the ebony case in which he kept his Bible. He is supposed to be the Dr. Taylor who was taken prisoner with other Royalists while besieging Cardigan castle. In 1646 he is found in partnership with two other deprived clergymen, keeping a school at Newton Hall, in the parish of Llanvihangel. It was while resident here that he attracted the friendship of one of his kindest patrons, Richard Vaughan, earl of Carbery, whose hospitable mansion, Golden Grove, is immortalized in the title of Taylor's still popular manual of devotion, and whose countess had the greater distinction of being the original of the "Lady" in Milton's *Comus*. It was also while resident in Wales that Taylor married his second wife, Joanna Bridges, who was generally understood to be a natural daughter of Charles I., and who owned a good estate, though probably impoverished by Parliamentarian exactions, at Mandinam, in Carmarthenshire. From time to time he appears in London in the company of his friend Evelyn, at whose table he met such men as Boyle, Berkeley, and Wilkins. Thrice he was imprisoned: in 1653–4 for a well-intended but injudicious preface to his *Golden Grove;* again in Chepstow castle, from May to October 1655, on what charge does not appear; and a third time in the Tower in 1657–8, on account of the indiscretion of his publisher, Royston, who had adorned his "Collection of Offices" with a print representing Christ in the attitude of prayer. This unsettled life, with its interruptions, harassments, and privations, would seem rather to have stimulated than to have stinted the productiveness of his genius. In 1647 appeared his most important work, *The Liberty of Prophesying*, and in the following year the complete edition of his *Apology for Authorized and Set Forms of Liturgy against the Pretence of the Spirit*, as well as his *Life of Christ, or the Great Exemplar*, a book which at once won a popularity it still in large measure retains. Then followed in rapid succession the *Twenty-seven Sermons*, "for the summer half-year," and the *Twenty-five* "for the winter half-year," *Holy Living*, *Holy Dying*, a controversial treatise on the Real Presence, the *Golden Grove*, and the *Unum Necessarium*, which by its Pelagianism gave great offence. During these years he was also busy with his *Ductor Dubitantium* (published in 1660), which he intended to be the standard manual of casuistry and ethics for the Christian people.

In 1658 settlement was at length reached through the kind offices of the earl of Carbery, who obtained for Taylor a lectureship in Lisburn. At first he declined a post in which the duty was to be shared with a Presbyterian, or, as he expressed it, "where a Presbyterian and myself shall be like Castor and Pollux, the one up and the other down," and to which also a very meagre salary was attached. He was, however, induced to take it, and found, near his patron's mansion on Lough Neagh, so congenial a retirement that even after he was raised to a bishopric he continued to make it his home. At the Restoration, instead of being recalled to England, as he probably expected and certainly desired, he was appointed to the see of Down and Connor, to which was shortly added the small and adjacent diocese of Dromore. He was also made a member of the Irish privy council and vice-chancellor of the university of Dublin. None of these honors were sinecures. Of the university he writes, "I found all things in a perfect disorder . . . . a heap of men and boys, but no body of a college, no one member, either fellow or scholar, having any legal title to his place, but thrust in by tyranny or chance." Accordingly he set himself vigorously to the task of framing and enforcing regulations for the admission and conduct of members of the university, and also of establishing lectureships. His episcopal labors were still more arduous. There were, at the date of the Restoration, about seventy Presbyterian ministers in the north of Ireland, and most of these were from the west of Scotland, and were imbued with the dislike of Episcopacy which distinguished the Covenanting party. No wonder that Taylor, writing to the duke of Ormonde shortly after his consecration, should have said, "I perceive myself thrown into a place of torment." His letters perhaps somewhat exaggerate the danger in which he lived, but there is no doubt that his authority was resisted and his overtures rejected. His writings also were ransacked for matter of accusation against him, "a committee of Scotch spiders being appointed to see if they can gather or make poison out of them." Here, then, was Taylor's opportunity for exemplifying the wise toleration he had in other days inculcated. These Presbyterians had, like himself, suffered under Cromwell for their loyalty, and might have been expected to evoke his sympathy; but the new bishop had nothing to offer them but the bare alternative—submission to episcopal ordination and jurisdiction or deprivation. Consequently, in his first visitation, he declared thirty-six churches vacant; and of these forcible possession was taken by his orders. At the same time many of the gentry were won by his undoubted sincerity and devotedness as well as by his eloquence. With the Romanist element of the population he was less successful. Ignorant of the English language, and firmly attached to their ancestral forms of worship, they were yet compelled to attend a service they considered profane, conducted in a language they could not understand. As Heber says, "No part of the administration of Ireland by the English crown has been more extraordinary and more unfortunate than the system pursued for the introduction of the Reformed religion." At the instance of the Irish bishops Taylor undertook his last great work, the *Dissuasive from Popery* (in two parts, 1664 and 1667), but as he himself seemed partly conscious, he might have more effectually gained his end by adopting the methods of Ussher and Bedell, and inducing his clergy to acquire the Irish tongue.

Nor were domestic sorrows awanting in these later years. In 1661 he buried, at Lisburn, Edward, the only surviving son of his second marriage. His oldest son, an officer in the army, was killed in a duel; and his second son, Charles, intended for the church, left Trinity College and became companion and secretary to the duke of Buckingham, at whose house he died. The day after his son's funeral, Taylor sickened, and, after a ten days' illness, he died at Lisburn on the 13th August, 1667, in the fifty-fifth year of his life and the seventh of his episcopate.

Taylor's fame has been maintained by the popularity of his sermons and devotional writings rather than by his influence as a theologian or his importance as an ecclesiastic. His mind was neither scientific nor speculative, and he was attracted rather to questions of casuistry than to the deeper problems of pure theology. His wide reading and capacious memory enabled him to carry in his mind the materials of a sound historical theology, but these materials were unsifted by criticism. His immense learning served him rather as a storehouse of illustrations, or as an armory out of which he could choose the fittest weapon for discomfiting an opponent, than as a quarry furnishing him with material for building up a completely designed and enduring edifice of systematized truth. Indeed, he had very limited faith in the human mind as an instrument of truth. "Theology," he says, "is rather a divine life than a divine knowledge." His great plea for toleration is based on the impossibility of erecting theology into a demonstrable science. "It is impossible all should be of one mind. And what is impossible to be done is not necessary it should be done." Differences of opinion there must be; but "heresy is not an error of the understanding but an error of the will." His aim in life was practical; his interests were in men rather than in ideas, and his sympathies were evoked rather by the experiences of individuals than by great movements. Of a decidedly poetic temperament, fervid and mobile in feeling, and of a prolific fancy, he had also the sense and wit that come of varied contact with men. All his gifts were made available for influencing other men by his easy command of a style rarely matched in dignity and color. With all the majesty and stately elaboration and musical rhythm of Milton's finest prose, Taylor's style is relieved and brightened by an astonishing variety of felicitous illustrations, ranging from the most homely and terse to the most dignified and elaborate. His sermons especially abound in quotations and allusions, which have the air of spontaneously suggesting themselves, but which must sometimes have baffled his hearers. This seeming pedantry is, however, atoned for by the clear practical aim of his sermons, the noble ideal he keeps before his hearers, and the skill with which he handles spiritual experience and urges incentives to virtue. But, through all his gorgeous eloquence and genial interest in human nature, there breaks from time to time some dead and labored irrelevancy, the growth of his training in scholastic dialects; for "like some other writers of the 17th century he seems almost to have two minds,—one tender, sweet, luxuriant to excess, the other hard, subtle, formal, prone to definition and logomachy."

The first collected edition of his works was published by Bishop Heber (with a life) in 1822, reissued after careful revision by Charles Page Eden, 1852–61. (M. D.)

TAYLOR, John (1580–1654), commonly called "The Water Poet," was born at Gloucester in August, 1580. Of his parentage and early boyhood very little is known, and that little is mainly to be gleaned from various scattered personal allusions in the numerous short writings of this prolific wit and rhymester. After fulfilling his apprenticeship to a waterman, he seems to have served (1596) in the fleet under the earl of Essex, and to have been present at the naval attack upon Cadiz. On his return to England he took up the trade of Thames waterman, and for a time at any rate was a collector of the dues exacted by the lieutenant of the Tower on all wines destined for London. The title of "Water Poet," which he owes to his occupation on the river, is a misnomer. Taylor was no poet, though he could string rhymes together with facility; his wit, which was vigorous and vulgar, found best expression in rollicking prose. He shows a broad sense of rough fun, occasionally of humor; but for the most part his comicalities would now meet with scanty appreciation. He had a very good opinion of himself, his writings, and his importance; and it was he himself who set forth that he was the "king's water poet" and the "queen's waterman." His literary performances can most easily and most satisfactorily be studied in the handsome quarto, containing all his productions, edited by Mr. C. Hindley, and published in 1872. His "works," sixty-three in number, first appeared in one large volume—now a rarity sought after by collectors—in 1630. He delighted in eccentric freaks, calculated in narration to astound both the sober country-folk and the somewhat skeptical Londoners. Thus, with a companion as feather-brained as himself, he once started on a voyage from London to Queensborough in a paper boat, with two stockfish tied to two canes for oars; before the journey's end was reached the frail boat collapsed, as might have been expected, though a qualified success finally met Taylor's efforts. The spirit of the bargee was in him, and he delighted in rough give-and-take; a rude lampoon was one of his favorite verbal weapons. Thus Thomas Coryat, the author of *Crudities*, having excited the literary waterman's ridicule, was rewarded with a ludicrous dedication in the production entitled *Taylor's Travels in Germanie*; again, the "water poet" indulged in abusive satire to his heart's content in an "effusion" which he called *A Kicksey-Winsey, or a Lerry Come-Twang*—a literary castigation which he inflicted upon those subscribers to a certain "work" of his who omitted to substantiate their promises. This production was entitled *The Penniless Pilgrimage, or the Moneyless Perambulation of John Taylor*, and consisted of an account of its author's pedestrian tour from London to Edinburgh; and to this work some sixteen hundred per-

PACIFIC SCHOOL

sons are said to have promised their support. Another wagering venture was a journey to Prague, where he is said to have been received and entertained by the queen of Bohemia in 1620. Two years later Taylor made "a very merry, wherry ferry voyage, or Yorke for my money," and in the ensuing year another water-journey, which he subsequently described in prose and verse as *A New Discovery by Sea with a Wherry from London to Salisbury.* At the outbreak of the Civil War Taylor forsook the river and retired to Oxford, where he tempted fortune by keeping a public house. His sympathies were wholly with the Royalists,—the Roysterists, as he called them once; and, when the town surrendered, the "water poet" returned to London and kept a public house under the sign of The Crown, in Phœnix Alley, Long Acre. He incurred some odium from his loyal observance of the king's death in the placement above his door of the sign of The Mourning Crown, and he was forced to take the latter down. With characteristic readiness he substituted for it his own portrait, with some doggerel lines underneath. It was here that in December, 1654, he died, and in the neighboring churchyard of St. Martin's-in-the-Fields his remains were laid.

At the most, Taylor can only be called an amusing and vulgarly clever pamphleteer; he wrote nothing worthy of remembrance save by the historian of the period in which he lived, by the antiquary, and by the enthusiastic student of the many straggling little by-ways of literature.

TAYLOR, Tom (1817–1880), dramatist and art critic, was born at Sunderland in 1817. After attending school there, and studying for two sessions at Glasgow University, he in 1837 entered Trinity College, Cambridge, of which he became a fellow. Subsequently he held for two years the professorship of English literature at University College, London. He was called to the bar (Middle Temple) in November, 1845, and went on the northern circuit until, in 1850, he became assistant secretary of the Board of Health. On the reconstruction of the board in 1854 he was made secretary, and on its abolition his services were transferred to the Local Government Act Office, a department of the Home Office created by the Sanitary Act of 1866. In his very early years Tom Taylor showed a predilection for the drama, and was in the habit of performing dramatic pieces along with a number of children in a loft over a brewer's stable. His first dramatic composition was a rhymed fairy tale or extravaganza, written in conjunction with Albert Smith and Charles Kenny, and performed in 1846. From this time he wrote for the stage continuously till the close of his life, his dramatic compositions or adaptations numbering in all over 100, amongst the best known of which are *Still Water Runs Deep*, *Victims*, the *Contested Election*, the *Overland Route*, the *Ticket of Leave Man*, *Anne Boleyn*, and *Joan of Arc*. He may perhaps be regarded as the first dramatist of his time, so far as general appreciation goes; and, if his chief concern was the construction of a popular acting play, his dramas possess at the same time considerable literary excellence, while the characters are clearly and consistently drawn, and the dialogue is natural, yet nervous and pointed. In his blank verse historical dramas, such as *Anne Boleyn* and *Joan of Arc*, he was not so successful. Taylor was also a very frequent contributor to the light magazine literature of the day. In 1872 he withdrew from public life, and, on the death of Shirley Brooks in 1873, he became editor of *Punch*. He occasionally appeared with success in amateur theatricals, more especially in the character of Adam in *As You Like It* and of Jasper in *A Sheep in Wolf's Clothing*. He had some talent for painting, and for many years was art critic to the *Times*. He died at Lavender Sweep, Wandsworth, 12th July, 1880.

Apart from the drama, his chief contributions to literature are his biographies of painters, viz.: *Autobiography of B. R. Haydon* (1853); *Autobiography and Correspondence of C. R. Leslie, R.A.* (1859); and *Life and Times of Sir Joshua Reynolds* (1865), which had been left in a very incomplete state by Mr. Leslie. His *Historical Dramas* appeared in one volume in 1877. He also edited, with a memorial preface, *Pen Sketches from a Vanished Hand, selected from Papers of the late Mortimer Collins.*

TAYLOR, Zachary[1] (1784–1850), president of the United States, was born in Orange county, Virginia, November 24, 1784. He entered the army as lieutenant in 1808, and rose to the rank of major in the war with Great Britain which followed. At the outbreak of the Mexican War he was in command of the American forces in Louisiana and Texas, and was directed to make the advance into the disputed territory which brought on the war. Beating the Mexicans in two battles, he followed them into Mexico, and there defeated Santa Anna in the crowning battle of his campaign, Buena Vista (1847). Dissatisfied with his treatment by the administration, he resigned and returned to the United States, where the Whig party nominated him and elected him president (1848). The struggle over the question of the admission of slavery to the territory taken from Mexico occupied his term of office, and he died at Washington, July 9, 1850.

TCHAD, Tsad, or Chad, Lake. See Africa, vol. i., p. 229, and Soudan.

TCHEREMISSES, or Cheremisses. See Finland, vol. ix., p. 191, and Russia, vol. xxi., pp. 87–89.

TCHERKASY (Polish *Czerkasy*), a district town of Russia, in the government of Kieff, and 90 miles by rail to the southeast of Kieff, on the right bank of the Dnieper. It is poorly built, mostly of wood; the population has rapidly increased lately, and has doubled since 1846, reaching 15,740 in 1883. There are now two gymnasiums for boys and girls, and several lower schools. The inhabitants (Little Russian) are mostly employed in agriculture and gardening. There is a brisk export trade in corn, refined sugar, tobacco, salt, and timber; raw sugar and manufactured goods are imported, principally by Jewish merchants.

---

[1] [By current records President Taylor was born in September, but the army registers fail to name the month. His father was a colonel in the Revolutionary war, and removed in 1785 to Louisville, Kentucky, where the distinguished son remained until, in his 24th year, he was given a lieutenant's commission in the place of an elder brother who had just died. His reputation was made in Indian warfare, from Fort Harrison, on the Wabash river, in 1812 to the battle of Okeechobee Swamp in 1837, by which, after the reputations of several of his predecessors had been ruined, he brought the Seminole war to a conclusion and gained the brevet-rank of brigadier general in the regular army (see vol. xxi. p. 577, note). In 1840 Taylor removed to Baton Rouge, and was there when the Texas troubles began. The current story is that Secretary Marcy wished Taylor to embroil the United States in a war with Mexico, by acting on inferential instructions as to crossing the Nueces river. He received positive orders, dated 13th January, 1846, under which he established himself on the Rio Grande, and from that time was zealous to promote the designs of the Polk administration. Acting with Corpus Christi as his base, Taylor cleared the lower valley of the Rio Grande of Mexican troops at Palo Alto and Resaca de la Palma, swept on into the state of Nuevo-Leon, and fought a series of battles which ended with the capitulation of Monterey on the 24th September, 1846. His progress was here interrupted by General Scott's campaign from Vera Cruz, to whom Taylor sent his best veterans. On the 21st February following, Santa Anna assailed him with 21,000 troops in the mountain pass of Buena Vista, about seven miles south of Saltillo, and was signally beaten. A few months later Taylor returned home, bearing the sobriquet of "Old Rough and Ready" and designated by popular acclaim for the Presidency of the United States. The Whig party nominated him at Philadelphia in 1848, because it had to respect the public wish or encounter defeat. But Henry Wilson, of Massachusetts, led a number of delegates from the convention, which, together with the Barnburner seceders from the National Democratic convention of the ensuing August, formed the new Free-soil party. From the beginning of his administration General Taylor had to confront the question of slavery extension, which grew out of the acquisition of territory from Mexico. It was held that these acquisitions came into the possession of the United States as free soil by Mexican law. Texas undertook to solve the difficulty by claiming sovereignty in New Mexico, which pretension Taylor denied, and ordered any invading troops from Texas to be driven out of the territory. Pending the settlement of this trouble by the Clay compromises of 1850, Taylor suddenly died. His son Richard was born in Florida, and died on the 12th April, 1879, having been a lieutenant-general in the Confederacy, and the last southern commander to surrender, which he did at Mobile to General Canby, 4th May, 1865. He defeated Banks in his Red River campaign of the previous year, and was known as an accomplished society man in Europe as well as in America.—Am. Ed.]

Tcherkasy, formerly Tcherkassk, was an important town of the Ukraine in the 15th century, and remained so, under Polish rule, until the revolt of Hmelnitski, when it became free. When West Ukraine was taken again by Poland, most of its inhabitants migrated to the left bank of the Dnieper. It was annexed by Russia in 1795.

TCHERNIGOFF, a government of Little Russia, on the left bank of the Dnieper, bounded by Moghileff and Smolensk on the N., Orel and Kursk on the E., Poltava on the S., and Kieff and Minsk on the W., has an area of 20,233 square miles. Its surface is an undulating plain, 650 to 750 feet high in the north, and from 370 to 600 feet in the south, deeply grooved by ravines and the valleys of the rivers. In the north, "beyond the Desna," about one-third of the area is under wood (which is rapidly disappearing), and marshes occur along the courses of the rivers; while to the south of the Desna the soil is dry, sometimes sandy, and assumes the characters of a steppe-land as one proceeds southward. Chalk deposits prevail in the north, and Eocene in the south. The government is watered by the Dnieper (which forms its western boundary for 178 miles) and its tributaries the Soj and the Desna. The latter, which flows through Tchernigoff for nearly 350 miles, is navigable, and timber is brought down its tributaries. Corn, linseed, timber, brandy, hemp, and sugar are shipped on the Dnieper, Soj, and Desna, and salt imported. The climate is much colder in the woody tracts of the north than in the south; the average yearly temperature at the town of Tchernigoff is 44.4° (January, 23°; July, 68.5°).

The population, which is rapidly increasing, reached 1,996,250 in 1883. It is chiefly Little Russian (85.6 per cent.); Great Russians (6.1 per cent.), mostly Raskolniks, and White Russians (5.6 per cent.) inhabit the northern districts. Jews have spread rapidly since last century, and now number more than 45,000. There are, besides, some 20,000 Germans as well as Greeks at Nyezhin. Agriculture is the principal occupation; in the north, however, many of the inhabitants are engaged in the timber trade and various domestic industries. Cattle-breeding is carried on in the central districts, and there were in 1883 572,200 horses, 515,300 cattle, and 948,000 sheep. Beet is extensively cultivated, and in 1884 2 million cwts. of beet-root were delivered to the thirteen sugar-works within the government. The culture of tobacco is also increasing, upwards of 500,000 cwts. being produced annually. Hemp is widely cultivated in the north, and the milder climate of the south encourages gardening. Bee-keeping is extensively carried on by the Raskolniks. Tar, pitch, and a large variety of wooden manufactures are largely produced in the forest districts, as also are woven fabrics, felts, and leather wares. Limestone, grindstones, china-clay, and building stone are quarried. Manufactures have begun to develop rapidly of late; by 1881 their yearly production reached £1,340,000 [$6,512,400] (£860,000 [$4,179,600] from sugar-works and distilleries). Trade is active, especially since the opening of the railway between Kieff and Kursk, which runs through Tchernigoff. The government is divided into fifteen districts, the chief towns (with populations in 1885) being Tchernigoff (19,000), Borzna (13,700), Glukhoff (16,450), Gorodnya (3550), Konotop (16,420), Kozelets (4430), Krolevets (9190), Mglin (10,880), Novgorod-Syeversk (8020), Novozybkoff (11,920), Nyezhin (43,020), Oster (3550), Sosnitsa (5650), Starodub (23,890 in 1880), and Surazh (3770). A number of unimportant towns (14 *posads* and 49 *myestechki*) possess municipal institutions.

TCHERNIGOFF, capital of the above government, stands on the right bank of the Desna, nearly half a mile from the river, 476 miles from Moscow. Far removed from the great channels of trade, its sole importance is as an administrative centre. Its houses are poorly built, and the streets are unpaved. The population (19,000 in 1885, one-third being Jews) is almost stationary. The ruins of its fortress, and the old cathedrals of Preobrazhenie and Borisoglebsk, founded in the 11th and 12th centuries, bear witness to the former importance of the town. Numerous graves scattered about, and now partly explored, speak of the battles which caused its decay.

Tchernigoff is known to have existed before the introduction of Christianity into Russia. In 907 it is mentioned in the treaty of Oleg as next to Kieff, and in the 11th century it became the capital of the principality of Syeversk and an important commercial city. The Mongolian invasion put an end to its growth. Lithuania annexed it in the 14th century, but it was soon seized by Poland, which held it until the 17th century. The great rising in 1648 rendered it independent until 1654, when the Cossacks accepted the protectorate of the czars of Moscow. In 1686 it was definitely annexed to Russia.

TCHERNOMORSK, a government of Caucasia, Russia, consisting of a narrow strip of land between the main Caucasus chain and the Black Sea, formerly inhabited by the Adyghe mountaineers of Caucasus. This strip, protected by the mountains from the cold winds of the north, is in respect of climate one of the most favored parts of the Black Sea littoral. Owing to extensive emigrations of its inhabitants to Turkey since the Russian conquest of 1864, it is very thinly peopled, the population numbering but 25,980, mostly Russians, on an area of 2824 square miles. The steep slopes of the Caucasus, whose summits range from 2000 to 10,000 feet, are furrowed by narrow gorges, and bear a luxuriant vegetation. The wild vine—a relic of former gardens—grows freely in the forests, which are almost impassable on account of the underwood and decaying trees. The moistness of the atmosphere contributes to the spread of the Caucasian fever, which is characteristic of the littoral. Notwithstanding the proximity of the mountains to the sea, a road is now being constructed along the coast,—for military reasons.

Agriculture is carried on, but only in the south,—gardening and the culture of the vine and tobacco being the chief occupations besides fishing and hunting. Some manufactures are rising up at Novorossiysk (3330 inhabitants) and Anapa (5350), the two principal towns, which also have some foreign trade. The region is a separate province under a military governor residing at Novorossiysk, where a new harbor is being constructed.

TCHISTOPOL, a district town of Russia, in the government of Kazañ, 90 miles to the southeast of that town, on the left bank of the Kama. Before 1781 it was a mere village (Tchistoye Pole), founded by runaway serfs; at present it is extending rapidly and becoming an industrial town, with flour-mills, distilleries, and a few cotton-mills. The merchants carry on a brisk trade in corn brought in from the fertile tracts of Ufa, and shipped down the Kama; manufactured wares are imported. The population in 1883 was 18,200.

TCHITA, capital of Transbaikalia, Eastern Siberia, stands 585 miles east of Irkutsk, on the Tchita river, half a mile above its junction with the Ingoda. It was founded in 1851; and military considerations led to the selection of this very small village to be the capital of Transbaikalia. Steamers on the Amur and Shilka do not penetrate so far as the upper Ingoda; they usually stay at Sryetensk, 320 miles distant. But the military supplies sent every year from Transbaikalia to the Amur region usually start from Tchita,—the forest-covered hills on the banks of the Ingoda supplying material for the construction of the barges (from 100 to 200 in number) on which these supplies are carried as soon as the melting of the snows in the mountains temporarily raises the water in the river to a sufficient height. Tchita is built of wood, with unpaved streets and wide open spaces. The dryness of the Buriat steppe close by prevents snow from accumulating to any depth, even when the cold is extreme; the merchandise accordingly which is forwarded from Irkutsk to the Nertchinsk district is brought to Tchita on carts, and is there loaded on sledges for the continuation of the journey down the frozen rivers. The population of Tchita in 1883 was 12,600. The inhabitants support themselves by agriculture, by trade in furs, cattle, hides, and tallow, which are bought from the Buriats, and in all kind of manufactured wares imported from Russia and Western Siberia.

TEA. This important food auxiliary, now in daily use as a beverage by probably one-half of the population of the world, is prepared from the leaves of one or more plants belonging to the natural order *Ternströmiaceæ.* The order includes the well-known ornamental genus of shrubs *Camellia*, to which indeed the tea-plants are so closely allied that by many systematic writers they are included in the same genus. The tea-plants have been cultivated in China for at least a thousand years.

Botany.

As is commonly the case with plants which have been long under cultivation, there is much doubt as to specific distinctions among the varieties of tea. Under the name of *Thea sinensis*, Linnæus originally described tea as a single species; but with fuller knowledge of the Chinese plants he established two species, *Thea Bohea* and *Thea viridis*, and it was assumed that the former was the source of black teas, while *Thea viridis* was held to yield the green varieties. In 1843, however, Mr. Robert Fortune found that, although the two varieties of the plant exist in different parts of China, black and green tea are made indifferently from the leaves of the same plant. The tea-plant is cultivated in China as an evergreen shrub, which grows to a height of from 3 to 5 feet. The stem is bushy, with numerous and very leafy branches; the leaves are alternate, large elliptical, obtusely serrated, veined, and placed on short channelled foot-stalks. The calyx is small, smooth, and divided into five obtuse sepals. The flowers are white, axillary, and slightly fragrant,—often two or three together on separate pedicels. The corolla has from five to nine petals, cohering at the base. The filaments are short, numerous, and inserted at the base of the corolla; the anthers are large and yellow, the style trifid, and the capsules three-celled and three-seeded.

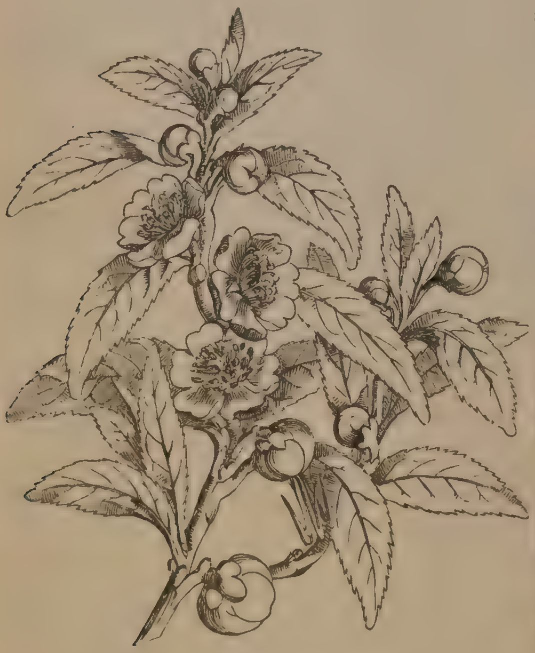

FIG. 1.—Tea-Plant (*Thea sinensis*).

The *viridis* varieties are hardier, and possess larger and brighter green leaves than belong to the *Bohea* variety. No strictly wild tea-plants have been discovered in China, but an indigenous tea-tree (*Thea assamica*) is found in Assam, which botanists now incline to regard as the parent species of all cultivated varieties. It differs in many respects from the Chinese plants. The indigenous Assam tea-plant is a tree attaining a height of from 15 to 20 feet, growing in the midst of dense moist jungle and in shady sheltered situations. Its leaves vary considerably in size, form, and venation, being usually smooth, thick, and leathery, lanceolate, ovate lanceolate, or oblong lanceolate. They are variously dotted with pellucid cells containing essential oil, and the number of such cells shown by the leaf is held to be an indication of the quantity of tea it will yield. The leaf of the Chinese plant never exceeds 4 inches in length, while that of the Assam tree reaches 9 inches and upwards. The Chinese plant is hardy, and capable of thriving under many different conditions of climate and situation; while the indigenous plant is tender and difficult of cultivation, requiring for its success a close, hot, moist, and equable climate. The characteristic venation of the leaf of the Chinese tea-plant is delineated in Fig. 2. In minute structure the leaf presents highly characteristic appearances. The under side of the young leaf is densely covered with fine one-celled thick-walled hairs, about 1 mm. in length and .015 mm. in thickness. These hairs entirely disappear with increasing age. The structure of the epidermis of the under side of the leaf, with its contorted cells, is represented (× 160) in Fig. 3. A further characteristic feature of the cellular structure of the tea-leaf is the abundance, especially in grown leaves, of large, branching, thick-walled, smooth cells (idioblasts), which, although they occur in other leaves, are not found in such as are likely to be confounded with or substituted for tea. The minute structure of the leaf in section is illustrated in Fig. 4.

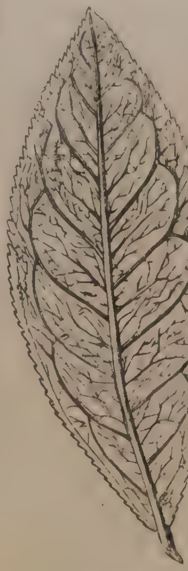

FIG. 2.—Tea-Leaf—full size.

Range of growth.

The cultivated varieties of tea, being comparatively hardy, possess an adaptability to climate excelled among food plants only by the wheat. The limits of actual tea cultivation extend from 39° N. lat. in Japan, through the tropics, to Java, Australia, Natal, and Brazil in the southern hemisphere. The tea-plant will even live in the open air in the south of England, and withstand some amount of frost, when it receives sufficient summer heat to harden its wood. But comparatively few regions are suited for practical tea-growing.

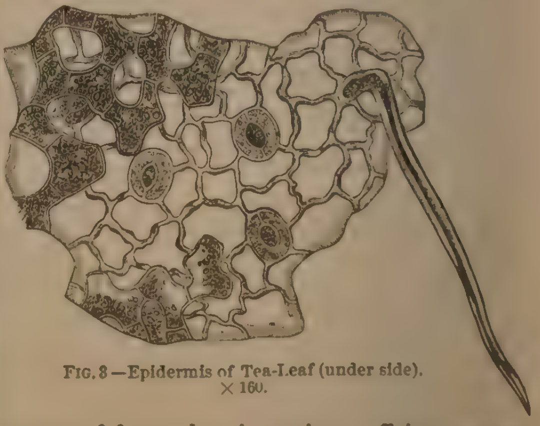

FIG. 3.—Epidermis of Tea-Leaf (under side). × 160.

Climate and soil.

A rich and exuberant growth of the plants is a first essential of successful tea cultivation. This is only obtainable in warm, moist, and comparatively equable climates, where rains are frequent and copious. The climate, indeed, which favors tropical profusion of jungle growth—still steaming heat—is that most favorable for the cultivation of tea, and such climate, unfortunately, is most prejudicial to the health of Europeans. It was formerly supposed that comparatively temperate latitudes and steep sloping ground afforded the most favorable situations for tea-planting, and much of the disaster which attended the early stages of the tea enterprise in India is traceable to this erroneous conception. Tea thrives best in light friable soils of good depth, through which water percolates freely, the plant being specially impatient of marshy situations and stagnant water. Undulating well-watered tracts, where the rain escapes freely, yet without washing away the soil, are the most valuable for tea gardens. As a matter of fact, many of the Indian plantations are established on hill-sides, after the example of known districts in China, where hill slopes and odd corners are commonly occupied with tea-plants.

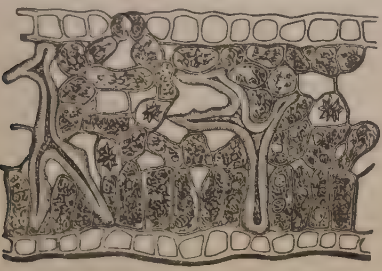

FIG. 4.—Section through Tea-Leaf.

History.

According to Chinese legend, the virtues of tea (*cha*, pronounced in the Amoy dialect *té*, whence the English name) were discovered by the mythical emperor Chinnung, 2737 B.C., to whom all agricultural and medicinal knowledge is traced. It is doubtfully referred to in the book of ancient poems edited by Confucius, all of which are previous in date to 550 B.C. A tradition exists in China that a knowledge of tea travelled eastward to and in China, having been introduced 543 A.D. by Bodhidharma, an ascetic who came from India on a missionary expedition, but that legend is also mixed with mythical and supernatural details. But it is quite certain, from the historical narrative of Lo Yu, who lived in the Tang dynasty (618–906 A.D.), that tea was already used as a beverage in the 6th century, and that during the 8th century its use had become so common that a tax was levied on its consumption in the 14th year of Tih Tsung (793). The use of tea in China in the middle of the 9th century is known from Arab sources (Reinaud, *Relation des Voyages*, 1845, p. 40). From China a knowledge of tea was carried into Japan, and there the cultivation was established about the beginning of the 13th century. Seed was brought from China by the priest Miyoye, and planted first in the south island, Kiushiu, whence the cultivation spread northwards till it reached the high limit of 39° N. To the south tea cultivation also spread into Tong-king and Cochin China, but the product in these regions is of inferior quality. Till well into the 19th century it may be said that China and Japan were the only two tea-producing countries, and that the product reached the Western markets only through the narrowest channels and under most oppressive restrictions.

In the year 1826 the Dutch succeeded in establishing tea gardens in Java. At an early period the East India Company of Great Britain, as the principal trade intermediary between China and Europe, became deeply interested in the question of tea cultivation in their Eastern possessions. In 1788 Sir Joseph Banks, at the request of the directors, drew up a memoir on the cultivation of economic plants in Bengal, in which he gave special prominence to tea, pointing out the regions most favorable for its cultivation. About the year 1820 Mr. David Scott, one of the company's servants, sent to Calcutta from the district of Kuch Behar and Rangpur—the very district indicated by Sir Joseph Banks as favorable for tea-growing—certain leaves, with a statement that they were said to belong to the wild tea-plant. The leaves were submitted to Dr. Wallich, Government botanist at Calcutta, who pronounced them to belong to a species of *Camellia*, and no result followed on Mr. Scott's communication. These very leaves ultimately came into the herbarium of the Linnean Society of London, and have authoritatively been pronounced to belong to the indigenous Assam tea-plant. Dr. Wallich's attribution of this and other specimens subsequently sent in to the genus *Camellia*, although scientifically defensible, unfortunately diverted attention from the significance of the discovery. It was not till 1834 that, overcome by the insistance of Captain Francis Jenkins, who maintained and proved that, called by the name *Camellia* or not, the leaves belonged to a tea-plant, Dr. Wallich admitted "the fact of the genuine tea-plant being a native of our territories in Upper Assam as incontrovertibly proved." In the meantime a committee had been formed by Lord William Bentinck, the governor-general, for the introduction of tea culture into India, and an official had already been sent to the tea districts of China to procure seed and skilled Chinese workmen to conduct operations in the Himalayan regions. The discovery and reports of Captain Jenkins led to the investigation of the capacities of Assam as a tea-growing country by Lord William Bentinck's committee. Evidence of the abundant existence of the indigenous tea-tree was obtained; and the directors of the East India Company resolved to institute an experimental establishment in Assam for cultivating and manufacturing tea, leaving the industry to be developed by private enterprise should its practicability be demonstrated. In 1836 there was sent to London 1 ℔ of tea made from indigenous leaves; in 1837 5 ℔ of Assam tea was sent; in 1838 the quantity sent was twelve small boxes, and ninety-five boxes reached London in 1839. In January, 1840, the Assam Company was formed, and thenceforward the cultivation of tea in India was carried on as a private commercial undertaking. The tea districts of India include, in the order of their priority, Assam, Dehra Dun, Kumaun, Darjiling, Cachar, Kangra, Hazaribagh, Chittagong, Tarai, and the Nilgiris (Madras).

Attempts were repeatedly made to introduce tea culture in Ceylon, under both Dutch and British authority. No permanent success was attained till about 1876, when the disastrous effects of the coffee-leaf disease induced planters to give serious attention to tea. Since that period the tea industry has developed in Ceylon with marvellous rapidity, and it has every prospect of taking the first rank among Singalese productions. Tea-planting has also been successfully established in Natal. But beyond the regions above enumerated the industry has never taken root. It has been tried in the West Indies, the Southern States of America, Brazil, Australia and the south of Europe; but cheap labor is a *sine qua non* of success. Tea can be picked in China, and the British East Indies for two or three pence a day of wages, and it is on such exceedingly moderate outlay that the margin of profit depends.

Tea industry in China.

Tea is more or less cultivated for local consumption in all provinces of China except the extreme north, but the regions from which it is exported are embraced within the provinces in the southeast—Kwang-tung, Fuh-keen, Keang-se, Che-keang, Keang-su, and Gan-hwuy. Black-tea manufacture belongs to the more southerly portion of these regions, the green-tea country lying to the north. The methods employed in cultivating the plants and in making tea in China differ widely in various districts, and the teas retained for native use—especially the high-class fancy teas which are never seen abroad, and would probably not bear exportation—undergo special manipulation. The teas exported are of three principal classes—black tea, green tea, and brick tea.

Cultivation.

In cultivation, the young plants are not ready for picking, till they are three years old, by which time they should be well established, throwing out young shoots or "flushes" with vigor and profusion. It is these tender shoots, with leaf-buds and expanding leaves, which alone are gathered for tea manufacture, and the younger the leaf-bud the better is the quality of the tea. According to Chinese statements there are four gatherings of leaves in the year. The first is made early in April, when the young leaf-buds are just unfolding, and these, covered below with their fine silky hairs, are taken for making pekoe or young hyson. The second gathering takes place about the beginning of May, another in July, and the fourth in August and September. On each succeeding occasion the product is less fragrant and valuable, and the final gathering is said to consist of large leaves of little value. These statements do not, however, accord with Indian experience.

The following brief outline of the Chinese tea-making processes is given by Mr. Ball (*Cultivation and Manufacture of Tea*):

Black tea.

"The leaves of black tea are exposed to the sun and air on circular trays and treated as hay, during which an incipient saccharine fermentation is supposed to take place in conjunction with a volatile oil. Various modifications of flavor are thus produced by the management of this fermentation; a loss of tannin takes place by the conversion of part of the tannic acid into sugar. During this change the leaves become flaccid, and slightly tinged or spotted with red or brown coloring matter, and give out a peculiar odor, approximating to, or, as some think, identical with, the odor of tea. A certain change in this odor is carefully watched by the workmen, this being an indication that the roasting must not be delayed. It is not necessary to wait till the leaves are spotted with red. They are then roasted in an iron vessel, and afterwards rolled with the hands, to express their juices. The roasting and rolling are repeated so long as any juices can be expressed from the leaves in the act of rolling. Finally, they are dried in sieves placed over a charcoal fire in drying tubes, during which the leaves are occasionally taken from the fire, and turned until completely dried. It is in this last stage of the process that the leaves turn black, though this change of color is mainly due to the process of manipulation previously to roasting, and not to the action of heat."

Green tea.

"The leaves of green tea are roasted also in an iron vessel, but as soon as gathered, without any previous manipulation, all heating or fermentation of the leaves being studiously avoided; they are then rolled as black tea, and finally dried in the same vessel in which they have been roasted, by constantly stirring and moving them about. They are also fanned to hasten evaporation, and the drying and formation of the peculiar characteristic color of this tea, which it gradually acquires in this process, and which resembles the bloom on some fruits."

The color of genuine green tea is entirely due to the rapid drying of the fresh leaves, which prevents the chlorophyll from undergoing any alteration. The green tea sent out of China is almost invariably faced or glazed with artificial coloring matter, principally with a powdered mixture of gypsum and Prussian blue.

Commercial varieties.

The names distinguishing commercial qualities of tea are almost entirely of Chinese origin. In general they indicate a gradation of qualities from the fine and delicate product of the young leaf-bud up to the hard and woody expanded and partly-grown leaf. The following list represents the ordinary series of qualities, beginning with the finest:

Black Tea.—Flowery pekoe, orange pekoe, pekoe, pekoe souchong, souchong, congou, bohea.

Green Tea.—Gunpowder, imperial, hyson, young hyson, hyson skin, caper.

Of these names, pekoe is derived from *pak-ho* (white hairs), the pekoes showing the fine downy tips of the young buds; souchong is from *siaou-chung*, little plant or sort; congou (*kung-fu*), labor; bohea (*wu-i*), the mountains in Fuh-keen, the centre of the black tea country; and hyson (*yü-tsien*), before the rains, or *tu-chun*, flourishing spring. Many other names occur in the trade denoting teas of special qualities or districts, such as oolong (black dragon) and twankay, from the district of that name in the province of Keang-su. Scented teas also form a special class of Chinese produce. In scenting the finished tea, either black or green is intimately intermixed with odoriferous flowers and left in a heap till the tea is fully impregnated with the odor, when the two substances are separated by sifting, and the tea so scented is immediately packed and excluded from the air.

Brick tea.

Brick tea is the special form in which tea is prepared for use throughout the vast tracts of Central Asia. It is made principally from broken leaves, stalks, and fragments of large leaves, compressed into blocks of various sizes. The bricks are of various degrees of compression, some being lightly squeezed into a loose mass and sewed up in cowhide bags, while others form compact resonant cakes, in which all trace of the original leaf structure is lost, with gilt characters impressed in their surface. Brick tea is much in demand over an area greater than the whole of Europe, and by many tribes it is stewed with milk, salt, and butter or other fat and eaten as a vegetable. The Russian factors established in Hoo-pih prepare two sizes of brick tea, which they send off in great quantities through the Kalgan Gate of the Great Wall.

Tea industry in India.

Under European supervision the cultivation and especially the manufacture of tea have in India undergone remarkable improvements. Indeed, the traditional and empirical teaching and processes of China proved a most serious stumbling block to the progress of the tea industry under Western auspices. The tea-plants now cultivated in India are of three principal classes—the indigenous Assam, the Chinese, and a hybrid between the two. By much crossing and intermixture the gradations from one extreme to the other are almost imperceptible. The best qualities of black teas are made from indigenous and high-class hybrid plants, but these are comparatively tender and require a close humid climate. The hardiness of the Chinese plants is their most important character, for, favorably situated, the Assam plant gives a larger yield of delicate young leaf during the season than any other.

Picking.

In favorable circumstances the tea-plant "flushes" or sends forth a fresh crop of tender young shoots from twenty to twenty-five times in the course of its growing and picking season of about nine months. The average annual yield per plant is very variable, but may be stated at about one-fifth of a ℔ of finished tea; and, as each acre of a garden holds 1500 to 1600 mature plants, the yield per acre may be from 300 to 350 ℔ per annum. The diagram (Fig. 5) from Col. Money's valuable practical treatise on the *Cultivation and Manufacture of Tea* illustrates the method in which a flush or shoot is picked, and the portions which go to make special classes of tea. The lines in the diagram show the points at which the shoot may be picked, and it is important that the lowest leaf taken should be so nipped off as to leave the bud in its axil uninjured on the branch, as from it the next flush will then develop. The three leaves at the growing point (*a*, *b*, *c*) yield pekoe, and the whole shoot down to and including *f* gives pekoe souchong. In the order of their age, the individual leaves manufacture into *a* flowery pekoe, *b* orange pekoe, *c* pekoe, *d* pekoe souchong, *e* souchong, and *f* congou. Were the flush further developed another leaf might be taken, which would be classed as bohea, but that is not a quality recognized by Indian growers. It is not, however, the practice to pick or treat leaves separately, the whole flush being manipulated together, and the tea is only separated into qualities by sifting after the manufacturing processes have been completed.

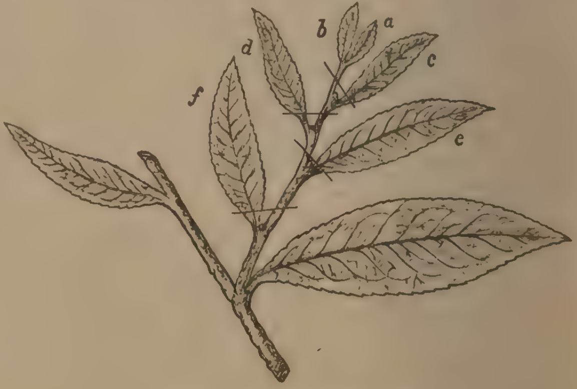

FIG. 5.—Mode of Picking Tea.

The manufacture of black tea is found to be an essentially

Manufacture. Black tea.

simple matter. Many of the processes employed by the Chinese are quite superfluous, and several of the manual operations which bulk largely in the Chinese manufacture, it is found, can with advantage be supplanted by mechanical agency. The whole object of the black-tea manufacture is to ferment, roll, and dry the leaf, and for that purpose the leaves undergo (1) withering, (2) rolling, (3) fermenting, and (4) firing or dholing. Between the fermenting and the firing operations it is desirable to expose the leaves to the direct sunlight for an hour or thereby. This cannot always be done, as it is impossible to keep the fermented leaves after they have attained their proper state; nevertheless, the best result is always attained in bright weather, when it is possible to expose the fermented leaves to the sun.

The fresh leaves from the garden, as they are brought in to the factory, are withered by being spread evenly over square wicker-work trays—leaf challanies—thickly or thinly as the weather is hot or cool. Thus they are left exposed to the air till they become quite soft and flaccid, folding together when pressed in the hand into a clammy mass without crackling or rebound. In cloudy or rainy weather it becomes necessary to wither by machine, acting on the leaves with artificially dried and heated air. Withering is a preliminary to rolling, in which the flaccid and velvety leaves are kneaded, twisted, and rolled back and forward over a table till the whole comes into a mashy condition by the exudation of juice. While in Chinese tea-making that juice is squeezed out of the leaves, in India it is most carefully lapped up and absorbed in the spongy mass. In hand-rolling as much as can be worked between two hands is operated on, and passed from man to man along the table till fully worked, when it is made up into a compressed ball and so put aside for fermenting. This process is the distinguishing feature of black-tea making, and on its sufficient accomplishment depends much of the character and quality of the tea made. The progress of the fermentation must be carefully watched, and at the point when by the color it is known to be sufficiently advanced the tea is in favorable weather sunned by exposure, thinly spread out to the sunlight, for about an hour. It is immediately thereafter fired, either by the fumes of burning charcoal or by a current of dried and heated air from one of the numerous machines now in use. With this single firing the process is completed, and the tea so finished is sifted by machinery into commercial qualities according to the size of the leaf.

For the entire range of manufacturing operations numerous forms of machinery and mechanical devices have been adapted and introduced in Indian gardens, so that, apart from picking the leaves, tea making has become practically a factory industry.

Green tea.

The manufacture of green tea is comparatively little prosecuted in India. In Europe the demand has greatly fallen away, and though the consumption is considerable in the United States, the supply is principally drawn from Japan, where its preparation is extensively practiced. The manufacture as carried on in the Northwestern Provinces resolves itself into a rapid rolling and drying of the leaf. Without permitting the leaves to wither after gathering, they are, if free from moisture, at once by exposure to a brisk heat sweated and softened for rolling. They are then without delay rolled as in black-tea manufacture, next spread out in the sun till they take a blackish tinge, then again rolled, and this rolling and exposure may be repeated yet a third time. When the rolling is completed the tea is placed in a highly heated pan, in which it is stirred about briskly till the whole mass becomes too hot to be worked by hand. Then it is tightly packed in a strong canvas bag, in which it is beaten by a heavy flat stick to consolidate it, and in this condition left for a night. Next day it is fired off in a pan, beginning with a high heat, which is gradually reduced during the nine hours or thereby of the operation, an incessant stirring and tossing being kept up the whole time. During this firing off the green color of the tea is developed; and Indian green tea never owes any of its color to "facing" with foreign substances.

Qualities of tea.

The qualities of a sample of tea and its commercial value can only with accuracy be determined by actual infusion and trial by a skilled tea-taster. Certain general and external appearances which indicate the class of a tea are obvious enough; but, although a pekoe may be readily distinguished from a souchong, the souchong of certain planters or districts may be more valuable than other pekoes. While it is impossible to define the conditions which determined the commercial value of an ordinary black tea, Col. Money lays down the following rules: the darker the liquor the stronger the tea, and the nearer the approach of the infused leaf to a uniform salmony brown the purer the flavor. Black tea of good quality should in infusion yield a clear bright brown liquor emitting a subdued fragrance, and in taste it should be mild, bland, and sweetish, with an agreeable astringency. Green tea yields a light-colored liquor of high fragrance, but thin, sharp, and somewhat rasping in taste as compared with black tea.

Chemistry.

The chemical components of tea leaves are essential oil, theine, tannin, boheic acid, quercetin, quercitannic acid, gallic acid, oxalic acid, gum, chlorophyll, resin, wax, albuminoids, coloring matters, cellulose, and mineral ash. Of these the first three—essential oil, theine, and tannin—are of importance in the infused beverage. The essential oil, on which the flavor of the tea depends, is present to the extent of from 0.6 to 1 per cent. Theine ($C_8H_{10}N_4O_2$) is an alkaloid identical with the caffeine obtained from coffee, and it is remarkable that the same substance is yielded by the maté or Paraguayan tea and the guarana of South America, and by the kola nut of Central Africa. The theobromine of cocoa is also closely allied to theine, and the characteristic components of the extract of meat similarly show certain points of contact with these stimulant bodies. To the tannin of tea infusions is due what is known as the strength of the tea. Prof. Dittmar has recently examined a number of China and Indian teas in regard to the proportions of theine and tannin in their infusions and to the dependence of these proportions on the time of infusion. The general result was that Chinese tea yields more theine and less tannin than Indian tea, and that in both cases 10 minutes' infusion extracts practically all the theine. Longer infusion adds only to the tannin that passes into the solution, and as excess of tannin impedes digestion, prolonged infusion is hurtful and ought to be avoided.

	Hyson. Green.	Congou. Black.
Volatile oil	0.79	0.60
Chlorophyll	2.22	1.84
Wax	0.28	0.00
Resin	2.22	3.64
Gum	8.56	7.28
Tannin	17.80	12.88
Theine[1]	0.43	0.46
Extractive matter	22.80	21.36
Coloring matter	23.60	19.12
Albumen	3.00	2.80
Woody fibre	17.08	28.32
	98.78[2]	98.30[2]

The quantitative composition of tea is of course subject to great variation. The analyses by Mulder given in the above table furnish a general idea of the proportion of constituents.

A series of investigations into a large number of teas has been carried out by Mr. G. W. Wigner (*Pharm. Jour.*, 3d series, vi. 261, 281, 402). In tea as imported he found large proportions of moisture which could be expelled on exposure to a temperature of 212° F. In a range of thirty-five samples the average moisture was equal to 7.67 per cent., the lowest—in a Chinese young hyson—being 4.84, while in several congous it exceeded 10 per cent. The ash in sixty-seven specimens of ordinary and special (undried) teas he found to average 5.78 per cent., the maximum being 7.02 and the minimum 5.17; and of that ash 54.50 per cent. was soluble in water. The proportion of extractive substances in twenty-four teas varied from 26.15 in a congou to 44.85 in Moyune young hyson. The total average nitrogen from sixty green teas, slightly faced, was 3.76, from sixty black teas 3.26, from six Assam teas 3.64, and from exhausted leaves 3.80 per cent.

Adulteration.

So long as the Western world remained almost exclusively dependent on China for its tea supply, adulteration was rampant and multiform in the trade. Especially among green and fancy teas there was scarcely such a thing as an unsophisticated sample to be obtained. The Chinese were also expert in fabricating an artificial gunpowder—appropriately known as "lie tea,"—which consisted of the sweepings of tea warehouses artfully made up with a paste of rice water. Paddy husks and many kinds of leaves faced with China clay, soapstone, catechu, and black lead also found their way abundantly into tea. On the European side, exhausted leaves were again dried, impregnated with catechu and gum, and faced up to do duty as fresh tea, and the leaves of numerous plants—sloe-thorn, hawthorn, willow, beech, plane, *Epilobium angustifolium*, etc.—were freely-worked up as tea. Adulterated tea is now, however, comparatively rare, largely owing to the watchfulness of the customs authorities. Moreover, as it is nearly as cheap to make tea from the leaves of the tea-plant as from those of any other herb, there is not much incentive to substitute the false for the real.

---

[1] The theine is certainly understated: more recent observers obtain from 1.8 to 3 per cent., and occasionally more.

[2] The mineral salts (ash) partly included in these totals amounted to 5.56 and 5.24 respectively.

Moral and physiological effects.

At a very early period in the European history of tea the probable effects of its use on the health and morals of the population attracted jealous attention, and a great deal was written, mostly in a hostile sense, on the subject. In 1678 we find Mr. Henry Savile writing to his uncle, Mr. Secretary Coventry, in sharp reproof of certain friends of his "who called for tea instead of pipes and bottles after dinner,—a base unworthy Indian practice, which I must ever admire your most Christian family for not admitting." And he adds, with an audible sigh, "the truth is all nations are growing so wicked as to have some of these filthy customs!" Some of the writers, however, although resolute for its banishment from the caddy, were willing to give it a place in the medicine chest. "Among many other novelties," says a medical writer in 1722, "there is one which seems to be particularly the cause of the hypochondriac disorders, and is generally known by the name of thea, or tea. It is a drug which of late years has very much insinuated itself, as well into our diet as regales and entertainments, though its occupation is not less destructive to the animal economy than opium, or some other drugs which we have at present learned to avoid."[1] Dr. Lettsom was the first medical writer who gave the public a reasonable and scientific account of the plant; but even he let the fear of its abuse run away with his judgment, asserting that "the first rise of this pernicious custom [that of drinking spirits to excess] is often owing to the weakness and debility of the system brought on by the daily habit of drinking tea; the trembling hand seeks a temporary relief in some cordial, in order to refresh and excite again the enfeebled system, whereby such persons almost necessarily fall into a habit of intemperance."[2] Jonas Hanway (*Essay on Tea*, 1756) was among its most vigorous assailants. "Men," he says, "seem to have lost their stature and comeliness, and women their beauty. . . . . What Shakespeare ascribes to the concealment of love is in this age more frequently occasioned by the use of tea." To these complaints echoes were not wanting, but after a while the tea-drinkers had it all their own way. In the meantime, however, tea was not without its apologists. To say nothing of our own familiar poets and essayists, its praises have been sung by Herrichen and by Francius in Greek verses, by Pechlin in Latin epigrams, by Pierre Petit in a Latin poem of five hundred lines, and by a German versifier, who celebrates, in a fashion of his own, its "burial and happy resurrection."[3] Huet, bishop of Avranches, has also paid his graceful tribute[4] to a stimulant to which, probably, no scholar was ever more indebted, and which he continued to enjoy at the age of ninety. Dr. Johnson draws his own portrait as "a hardened and shameless tea-drinker, who for twenty years diluted his meals with only the infusion of this fascinating plant; whose kettle had scarcely time to cool; who with tea amused the evening, with tea solaced the midnight, and with tea welcomed the morning."[5]

Authorities are not yet by any means agreed as to the exact physiological influence and value of tea. The very striking fact that theine is precisely the characteristic constituent of coffee, maté, guarana and the kola nut, all substances eagerly sought after in different quarters of the globe, serves to show that the alkaloid satisfies some craving of the human system, although what its effect is has not yet been certainly determined. The quantity of theine consumed even by the most hardened tea-drinker is exceedingly minute, and there are not wanting authorities who assert that it is practically inert, an assertion surely contradicted by the general instinct of the race. What is indisputable about tea drinking is that it forms an agreeable means of imbibing the proportion of water necessary in human nutrition, which, being taken hot, communicates to the system a diffused warm glow. Further, as used by Western communities, it is a medium of taking, in the form of sugar and cream, no inconsiderable amount of real nutriment. The other effects of tea are more a matter of general impression than of ascertained scientific reality. Its virtues have nowhere been better summarized than by the earliest Chinese writer on the subject, the above-mentioned Lo Yu, who says, "It tempers the spirits and harmonizes the mind, dispels lassitude and relieves fatigue, awakens thought and prevents drowsiness, lightens or refreshes the body, and clears the perceptive faculties." The gentle exhilaration which accompanies the moderate use of tea is not followed by the depression which succeeds the use of alcoholic stimuli. Experience has proved that it sustains the frame under severe muscular or mental exercise without causing subsequent exhaustion and collapse. Tea is frequently found to be beneficial to sufferers from nervous headache, and it counteracts to some extent the effects of alcohol and of opiates. Taken in excess it produces cerebral excitement, sleeplessness and general nervous irritability. The tannin contained in its infusions also interferes with the flow of the saliva, diminishes the digestive activity of the stomach, and impedes the action of the bowels. In this view the large quantity of strong tea used by the poor—and especially by the sedentary poor,—while serving to blunt the keen tooth of hunger, must work incalculable havoc with the digestive and nervous systems of the consumers.

Commerce and statistics.

It is a remarkable fact that no mention of tea is made by Marco Polo, and that no knowledge of the substance appears to have reached Europe till after the establishment of intercourse between Portugal and China in 1517. The Portuguese, however, did little towards the introduction of the herb into Europe, and it was not till the Dutch established themselves at Bantam early in the 17th century that these adventurers learned from the Chinese the habit of tea drinking and brought it to Europe.

The earliest mention of tea by an Englishman is probably that contained in a letter from Mr. Wickham, an agent of the East India Company, written from Firando in Japan, on the 27th June, 1615, to Mr. Eaton, another officer of the company, resident at Macao, and asking for "a pot of the best sort of *chaw*." How the commission was executed does not appear, but in Mr. Eaton's subsequent accounts of expenditure occurs this item—"three silver porringers to drink chaw in."

It was not till the middle of the century that the English began to use tea, and they also received their supplies from Java till in 1686 they were driven out of the island by the Dutch. At first the price of tea in England ranged from £6 to £10 [$29.16 to $48.60] per ℔. In the *Mercurius Politicus*, No. 435, of September, 1658, the following advertisement occurs: "That excellent and by all Physitians approved China Drink called by the Chineans *Tcha*, by other nations *Tay, alias Tee*, is sold at the Sultaness Head, a cophee-house in Sweetings Rents, by the Royal Exchange, London." Thomas Garway, the first English tea dealer, and founder of the well-known coffee-house, "Garraway's," in a curious broadsheet, *An Exact Description of the Growth, Quality, and Virtues of the Leaf Tea*, issued in 1659 or 1660, writes, "in respect of its scarceness and dearness, it hath been only used as a regalia in high treatments and entertainments, and presents made thereof to princes and grandees." In that year he purchased a quantity of the rare and much-prized commodity, and offered it to the public, in the leaf, at fixed prices varying from 15s. to 50s. [$3.64 to $12.15] the ℔, according to quality, and also in the infusion, "made according to the directions of the most knowing merchants and travellers into those eastern countries." In 1660 an Act of the first parliament of the Restoration imposed a tax on "every gallon of chocolate, sherbet, and tea, made and sold, to be paid by the maker thereof, eightpence [16⅔ c.]" (12 Car. II. c. 23).

Pepys's often-quoted mention of the fact that on the 25th September, 1660, "I did send for a cup of tee, a China drink, of which I never had drunk before," proves the novelty of tea in England at that date. In 1664 we find that the East India Company presented the king with 2 ℔ and 2 oz. of "thea," which cost 40s. [$9.72] per ℔, and two years afterwards with another parcel containing 22¾ ℔, for which the directors paid 50s. [$12.15] per ℔. Both parcels appear to have been purchased on the Continent. Not until 1677 is the Company recorded to have taken any steps for the importation of tea. The order then given to their agents was for "teas of the best kind to the amount of 100 dollars." But their instructions were considerably exceeded, for the quantity imported in 1678 was 4713 ℔, a quantity which seems to have glutted the market for several years. The annals of the Company record that, in February, 1684, the directors wrote thus to Madras: "In regard thea is grown to be a commodity here, and we have occasion to make presents therein to our great friends at court, we would have you to send us yearly five or six canisters of the very best and freshest thea." Until the Revolution no duty was laid on tea other than that levied on the infusion as sold in the coffee-houses. By 1 William and Mary c. 6, a duty of 5s. [$1.21½] per ℔ and 5 per cent. on the value was imposed. For several years the quantities imported were very small, and consisted exclusively of the finer sorts. The first direct purchase in China was made at Amoy, the teas previously obtained by the Company's factors having been purchased in Madras and Surat, whither it was brought by Chinese junks after the expulsion of the British from Java. During the closing years of the century the amount brought over seems to have been, on the average, about 20,000 ℔ a year. The instructions of 1700 directed the supercargoes to send home 300 tubs of the finer green teas and 80 tubs of bohea. In 1703 orders were given for "75,000 ℔. Singlo (green), 10,000 ℔ imperial, and 20,000 ℔ bohea." The average price of tea at this period was 16s. [$3.89] per ℔.

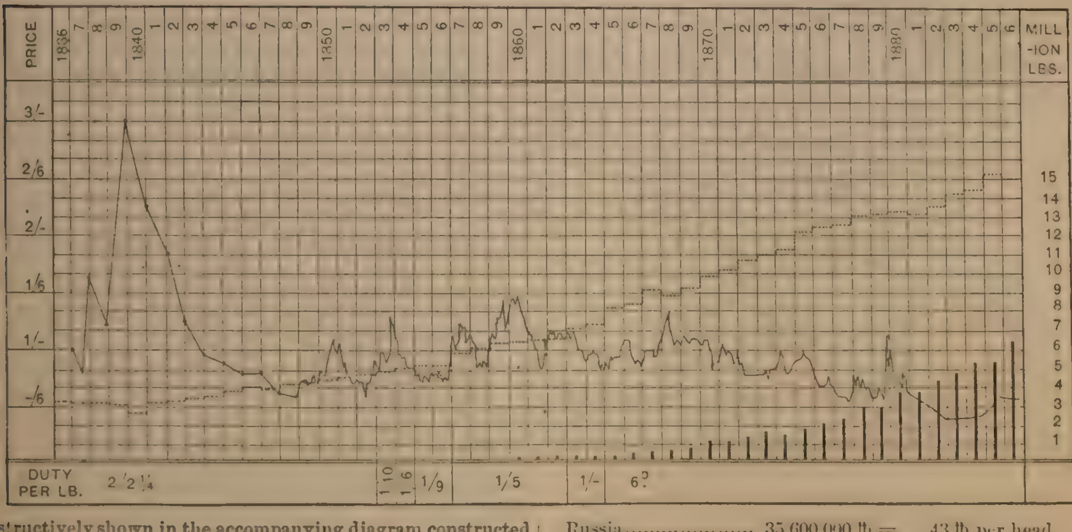
[5] *Literary Magazine*, vol. ii., No. 13 (1757).

During the 100 years from 1710 to 1810 the aggregate sale of tea by the East India Company amounted to 750,219,016 ℔, worth £129,804,595 [$630,850,331.70], of which 116,470,675 ℔ was re-exported. The duties during that century (excepting a period of eleven years, 1784–95, when they were only 12½ per cent.) were excessive, amounting to about 200 per cent. on the value of common teas. The results of so enormous a tax were the creation of a gigantic smuggling trade, extensive adulteration of imported teas, and much fabrication of counterfeit tea within the country. Probably the duty-paid tea did not represent more than half what was consumed under the name of tea. The following table exhibits the principal facts connected with the trade during the period of the Company's monopoly, which terminated on the 22d of April, 1834, when the trade was thrown open to all, the prices quoted being those of good qualities in the Company's warehouse or in bond :

	Average Price per ℔.	Rates of Duty.	Home Consumption. ℔.
1728	[32/6 (duty included)]...	4/ per ℔, and £13, 18/7½ per cent....................	1,493,626
1760	....	1/ per ℔, and £43, 18/7½ per cent....................	3,860'976
1782	5/ congou ; 9/10 hyson...	1/1⅜ per ℔, and £55, 15/10 per cent....................	6,202,257
1783	....	....	4,741,52
1784	4/10 congou ; 8/3 hyson.	£12, 10/ per cent............	10,150,700
1785	4/3 congou ; 6/9 hyson ..	....	14,800,932
1786	4/6 congou ; 7/1 hyson...	....	15,851,747
1795	3/9 congou ; 6/4 hyson...	£20 per cent..................	21,342,845
1801	3/5 congou ; 5/6 hyson...	£50 per cent., £20 under 2/6..............................	23,730,150
1821	3/ congou ; 5/4 hyson ...	£100 and £96 per cent...	26,754,537
1833	2/6½ congou ; 4/2 hyson	....	31,829,620

The progressive increase in the consumption of tea in the United Kingdom during 50 years from 1836 till 1886 is instructively shown in the accompanying diagram constructed by Messrs. J. C. Sillar & Co., of London. The dotted line represents the average monthly consumption in each year; the fluctuations in price of good sound congou are traced by the black line; and the years in which reduced customs duty came into operation are indicated along the base. From 1860 onwards the amount of Indian tea entered for home consumption is shown in monthly average by a black column. This column brings out the remarkable fact that the Indian tea consumed in the United Kingdom in a year now exceeds the total consumption of all kinds in 1860, and is more than double the whole quantity used fifty years ago.



The following table shows the growth of the British tea trade for five years ending 1885:

	India.	Ceylon.	China.	Hong-Kong.	Total Imports.	Home cons'mt'n
1881	45,434,130	171,676	151,749,592	10,445,758	209,801,622	160,225,911
1882	53,576,690	507,081	142,706,457	10,820,915	210,663,133	165,069,339
1883	59,252,435	2,005,510	145,249,136	10,863,695	222,262,431	170,828,431
1884	63,208,309	2,210,983	134,297,091	9,411,477	213,877,759	175,090,875
1885	63,794,025	4,242,244	131,234,354	8,353,829	212,143,820	182.443,215

The consumption of tea in the United Kingdom per head was in 1840 1.22 ℔, which increased in 1850 to 1.86 ℔; in 1860 it reached 2.67 ℔, in 1870 3.81 ℔, in 1880 4.06 ℔, and now (1887) it is about 5 ℔.

Next to the United Kingdom, the greatest tea-importing nation is the United States. Notwithstanding that tea has from 1873 been duty free (duty 25 cents per ℔ in 1870, 17.72 in 1871, and 15 in 1872), the habit of tea drinking does not grow in America as it is found to do in the British Isles, as is shown by the accompanying table. Of the 72,104,956 ℔ of tea imported into the United States in the year ended June, 1885, 35,895,835 ℔ was Chinese, 32,156,032 came from Japan, and 3,540,148 ℔ came from England. Nearly 6,000,000 ℔ was re-exported, principally to Canada.

Year ending 30th June.	℔ entered for Consumption.	Per Head.
1870	40,812,189	1.06
1871	46,972,788	1.19
1872	34,224,494	0.84
1873	106,423,570	2.55
1875	64,708,079	1.47
1880	72,159,266	1.44
1881	81,949,796	1.59
1882	79,030,854	1.50
1883	70,771,225	1.31
1884	65,774,234	1.18
1885	69,820,172	1.22

Next to the English, the Dutch are the greatest consumers of tea outside of China; and the only other considerable tea-using nation is Russia. The following table gives the amount of tea imported in the year 1884 by the principal tea-drinking countries:

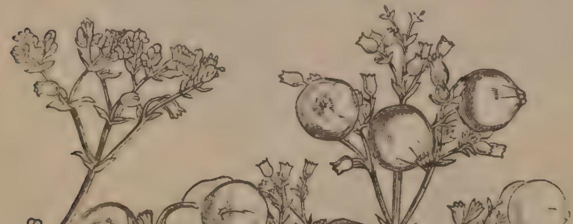
Russia........................	35,600,000 ℔ =	.43 ℔ per head.	
Holland......................	3,900,000 " =	.91	"
Denmark.....................	820,000 " =	.04	"
New South Wales......	8,437,981 " =	9.15	"
Victoria......................	11,524,205 " =	11.99	"
South Australia	2,229,993 " =	7.00	"
Queensland	2,757,277 " =	8.75	"
Cape of Good Hope....	1,295,942 " =	5.00	"

By this table the Australian colonists come out as the most inveterate tea-drinkers in the world. The quantity received by Holland in 1884 was 2,250,000 ℔ less than the imports of 1883, but the average of recent times has been 4,500,000 ℔.

The quantity consumed in China has been estimated as high as 2000 millions of pounds annually, being at the rate of a little more than 5 ℔ per head of the population; and, considering the tea-drinking habits of the people, the estimate is by no means extravagant. In this light it may be safe to affirm that the amount of tea used yearly throughout the world reaches the gigantic total of 2500 millions of pounds.

Bibliography.—The literature of tea is very copious but much scattered. The following works may be named: Bontekoe, *Tractat van het excellenste Kruyd Thee*, The Hague, 1679; Sylvestre Dufour, *Traités Nouveaux et Curieux du Café, du Thé, et du Chocolat*, 2d ed., Lyons, 1688 (translation of 1st edition by John Chamberlayne, London, 1685; translations also in Spanish and Latin); J. G. Houssaye, *Monographie du Thé*, Paris, 1843; Robert Fortune, *Three Years' Wanderings in China*, London, 1847; Id., *A Journey to the Tea Countries of China*, London, 1852; S. Ball, *Tea Cultivation in China*, London, 1848; J. J. L. L. Jacobson, *Handboek voor de Kultuur en Fabrikatie van Thee*, 3 vols., 1843; S. A. Schwarzkopf, *Die narkotischen Genussmittel*—i. *Der Thee*, Halle, 1881; Lieut.-Col. E. Money, *Cultivation and Manufacture of Tea*, 3d ed., London, 1878; F. T. R. Deas, *Young Tea Planter's Companion*, London, 1886. See also parliamentary papers and official publications of Indian Government; *Jour. Roy. Asiatic Soc.*; *Jour. Agri. and Horti. Soc. of India*; *Soc. of Arts Journ.*, *etc.* (J. PA.)

TEAK[1] may justly be called the most valuable of all known timbers. For use in tropical countries it has no equal, and for certain purposes it is preferable to other woods in temperate climates also. Its price is higher than that of any other timber, except mahogany.[2] Great efforts have been made to find substitutes, but no timber has been brought to market in sufficient quantities combining the many valuable qualities which teak possesses.



Teak (*Tectona grandis*).

The first good figure and description of the tree was given by Rheede.[3] The younger Linnæus called it *Tectona grandis*. It is a large deciduous tree, of the natural order *Verbenaceæ*, with a tall straight stem, a spreading crown, the branchlets four-sided, with large quadrangular pith. It is a native of the two Indian peninsulas, and is also found in the Philippine Islands, Java, and other islands of the Malay Archipelago. In India proper its northern limit is 24° 40′ on the west side of the Aravalli Hills, and in the centre near Jhansi, in 25° 30′ N. lat. In Burmah it extends to the Mogoung district, in lat. 25° 10′. In Bengal or Assam it is not indigenous, but plantations have been formed in Assam as far as the 27th parallel. In the Punjab it is grown in gardens to the 32d.

Teak requires a tropical climate, and the most important forests are found in the moister districts of India, where during the summer months heavy rains are brought by the southwest monsoon, the winter months being rainless. In the interior of the Indian peninsula, where the mean annual rainfall is less than 30 inches, no teak is found, and it thrives best with a mean annual fall of more than 50 inches. The mean annual temperature which suits it best lies between 75° and 81° Fahr. Near the coast the tree is absent, and the most valuable forests are on low hills up to 3000 feet. It grows on a great variety of soils, but there is one indispensable condition—perfect drainage or a dry subsoil. On level ground, with deep alluvial soil, teak does not often form regularly shaped stems, probably because the sub-soil drainage is imperfect.

During the dry season the tree is leafless; in hot localities the leaves fall in January, but in moist places the tree remains green till March. At the end of the dry season, when the first monsoon rains fall, the fresh foliage comes out. The leaves, which stand opposite, are from 1 to 2 feet in length and from 6 to 12 inches in breadth. On coppice shoots the leaves are much larger, and not rarely from 2 to 3 feet long. In shape they somewhat resemble those of the tobacco plant, but their substance is hard and the surface rough. The small white flowers are very numerous, on large erect cross-branched panicles, which terminate the branches. They appear during the rains, generally in July and August, and the seed ripens in January and February. On the east side of the Indian peninsula, the teak flowers during the rains in October and November. In Java the forests are leafless in September, while during March and April, after the rains have commenced, they are clothed with foliage and the flowers open. During the rainy season the tree is readily recognized at a considerable distance by the whitish flower panicles, which overtop the green foliage, and during the dry season the feathery seed-bearing panicles distinguish it from all other trees. The small oily seeds are enclosed in a hard bony 1–4 celled nut, which is surrounded by a thick covering, consisting of a dense felt of matted hairs. The fruit is enclosed by the enlarged membranous calyx, in appearance like an irregular plaited or crumpled bladder. The tree seeds freely every year, but its spread by means of self-sown seed is impeded by the forest fires of the dry season, which in India generally occur in March and April, after the seeds have ripened and have partly fallen. Of the seeds which escape, numbers are washed down the hills by the first heavy rains of the monsoon. These collect in the valleys, and it is here that groups of seedlings and young trees are frequently found. A portion of the seed remains on the tree; this falls gradually after the rains have commenced, and thus escapes the fires of the hot season. The germination of the seed is slow and uncertain; a large amount of moisture is needed to saturate the spongy covering; many seeds do not germinate until the second or third year, and many do not come up at all.

---

[1] The Sanskrit name of teak is *saka*, and it is certain that in India teak has been known and used largely for considerably more than 2000 years. In Persia teak was used nearly 2000 years ago, and the town of Siraf on the Persian Gulf was entirely built of it. *Saj* is the name in Arabic and Persian; and in Hindi, Mahratti, and the other modern languages derived from Sanskrit the tree is called *sag, sagwan*. In the Dravidian languages the name is *teka*, and the Portuguese, adopting this, called it *teke, teca*, whence the English name.

[2] The rate in the London market since 1860 has fluctuated between £10 and £15 [$48.60 and $72.90] per load of 50 cubic feet.

[3] *Hortus Malabaricus*, vol. iv. tab. 27, 1683.

The bark of the stem is about half an inch thick, gray or brownish gray, the sapwood white; the heartwood of the green tree has a pleasant and strong aromatic fragrance and a beautiful golden-yellow color, which on seasoning soon darkens into brown, mottled with darker streaks. The timber retains its aromatic fragrance to a great age. On a transverse section the wood is marked by large pores, which are more numerous and larger in the spring wood, or the inner belt of each annual ring, while they are less numerous and smaller in the autumn wood or outer belt. In this manner the growth of each successive year is marked in the wood, and the age of a tree may be determined by counting the annual rings.

The principal value of teak timber for use in warm countries is its extraordinary durability. In India and in Burmah beams of the wood in good preservation are often found in buildings several centuries old, and instances are known of teak beams having lasted more than a thousand years.[1] Being one of the few Indian timbers which are really durable, teak has always been used for buildings, particularly for temples, and in India it has been the chief timber employed for ship-building. When iron commenced to be extensively used for the last-named purpose, it was supposed that the demand for teak would decrease. This, however, has not been the case, for the wood is still very largely used for the backing of iron-clads and for decks of large vessels. It is also used for furniture, for door and window frames, for the construction of railway carriages, and for many other purposes. White ants eat the sapwood, but rarely attack the heartwood of teak. It is not, however, proof against the borings of the teredo, from whose attacks the teak piles of the wharves in the Rangoon river have to be protected by a sheathing of metal.

Once seasoned, teak timber does not split, crack, shrink, or alter its shape. In these qualities it is superior to most timbers. In contact with iron, neither the iron nor the teak suffers, and in this respect it is far superior to oak. It is not very hard, is easily worked, and takes a beautiful polish. It has great elasticity and strength, and is not very heavy. The average weight of perfectly seasoned wood fluctuates between 38 and 46 ℔ per cubic foot.[2] Its weight, therefore, is a little less than that of English oak. Green teak timber, however, is heavier than water, and unless thoroughly seasoned it cannot be floated. In Burmah, therefore, where the rivers are used to float the timber to the seaports, a peculiar mode of seasoning teak by girdling has been practiced from time immemorial. Girdling consists in making a deep circular cut through bark and sap into the heartwood, so as completely to sever communication between bark and sapwood above and below the cut. In teak, as in oak and other trees with well-marked heartwood, the circulation of the sap only takes place in the sapwood, and the girdled tree therefore dies after a few days if the operation has been effectually performed. But if even the smallest band of sapwood is left connecting the outer layers of wood above and below the girdle, the tree is not killed, and often recovers completely. The girdled tree is allowed to stand one or two years, and longer if a very large-sized tree. Being exposed to the wind and to the action of the sun, the timber of a girdled tree seasons more rapidly and more completely than that of a tree felled green. The teak produced in the presidencies of Madras and Bombay and in the Central provinces is as a rule felled green, and even when dry it generally is a little heavier than the timber from Burmah.[3] For a long time to come, the rivers of Burmah and Siam will continue to afford the most convenient and most economical routes for the transport of timber. Indeed the forests drained by the Salwin and its feeders are not likely ever to be worked otherwise than on the present plan, under which the logs are floated singly over the rapids and are caught and rafted lower down, at the kyodan or rope station, 70 miles above Maulmain.

As already mentioned, teakwood contains an aromatic oil, which gives it a peculiarly pleasant smell and an oily surface when fresh cut. To this oil may probably with justice be ascribed its great durability. In Burmah oil is extracted from the timber on a small scale, for medicinal purposes, by filling an earthen pot, which is placed inverted upon another, with chips of wood, and putting fire round it, upon which the oil runs down into the lower vessel.

According to the color and texture of the wood, several varieties of teak are distinguished in India, Burmah, and Java; in the timber trade, however, these distinctions are of no importance. Teak as well as other trees, when standing isolated, forms side branches far down the stem, and the wood of such trees is more knotty and wavy, and generally heavier and darker-colored than the timber of trees which have grown close together in a dense forest. Apart from the manner in which the tree had grown up in the forest, soil, elevation, and climate have a great influence upon the grain and the mechanical qualities of teak as of other timbers. Most of the larger logs brought to market have an irregular crack or hollow in the centre, which commences at the butt and often runs up a long way. There is little doubt that this is generally due to the action of the fires, which scorch and often destroy the bark of young trees. Such external injuries are apt to induce decay in the wood. Moreover, most teak seedlings which come up naturally are cut down to the ground by the fires of the hot season; some are killed, but many sprout again during the rains, and this is generally repeated year after year, until a sapling is produced strong enough to outlive the fire. Such saplings have a very large pith, which dries up, causing a hollow in the heart. Or a piece of the old shoot killed by the fire is enclosed by the new wood, and this also is apt to give rise to a hollow.

The leaves of the teak tree contain a red dye, which in Malabar was formerly used to dye silk and cotton. Natives of Burmah use the leaves as plates, to wrap up parcels, and for thatching.

In its youth the tree grows with extreme rapidity. Two-year-old seedlings on good soil are 5 to 10 feet high, and instances of more rapid growth are not uncommon. In the plantations which have been made since 1856 in Burmah, the teak has on good soil attained an average height of 60 feet in 15 years, with a girth, breast high, of 19 inches. This is between 16° and 18° N. lat., with a mean annual temperature of 78° F. and a rainfall of 100 inches. In the Burmah plantations it is estimated that the tree will, under favorable circumstances, attain a diameter of 24 inches (girth 72 inches) at the age of 80. Timber of that size is marketable, but the timber of the natural forests which is at present brought to market in Burmah has grown much more slowly, the chief reason being the annual forest fires, which harden and impoverish the soil. In the natural forests of Burmah and India teak timbers with a diameter of 24 inches is never less than 100 and often more than 200 years old. In future, the timber grown in plantations and in forests under regular management may be expected to grow much faster: and there is no ground for anticipating that rapidly grown timber will be less valuable than that of slow growth, which is at present brought to market.

Like the other trees of the dry deciduous forest, teak does not attain any extraordinary size. The trees are not generally more than 100 to 150 feet high, even under the most favorable circumstances, and stems more than 100 feet to the first branch are not often found. Exceptionally tall trees were measured in 1861 in the Gwaythay forest in Pegu, east of the Sitang river, on gneiss. The stems had 106 to 114 feet to the first branch, with a girth, at 6 feet off the ground, from 7 to 16 feet. Larger girths, up to 25 feet, are not uncommon.

The teak tree does not usually form pure forests. It is associated with bamboos and a great variety of other trees, which have little market value, and, as a rule, thrives best in such company. Hence in the plantations established in Burmah, the object has been to raise forests of teak mixed with bamboos and other trees.

Most of the teak timber produced is consumed in India.

---

[1] In one of the oldest buildings among the ruins of the old city of Vijayanagar, on the banks of the Tungabhadra in southern India, the superstructure is supported by planks of teakwood 1½ inches thick. These planks were examined in 1881; they were in a good state of preservation and showed the peculiar structure of teak timber in a very marked manner. They had been in the building for 500 years (*Indian Forester*, vol. vii. p. 260). In the wall of a palace of the Persian kings near Baghdad, which was pillaged in the 7th century, two Americans found in 1811 pieces of Indian teak which were perfectly sound (Onseley, *Travels in Various Countries of the East*, vol. ii. p. 280, note 67). In the old cave temples of Salsette and elsewhere in western India pieces of teak have been found in good preservation which must have been more than 2000 years old.

[2] At 44.8 ℔ per cubic foot a load of 50 cubic feet weighs a ton (2240 ℔), hence in the Burmah ports a ton of teak timber is taken as equivalent to a load of 50 cubic feet.

[3] It has been erroneously stated that the tree in Burmah is tapped for its oil before felling.

The produce of the magnificent forests of Travancore, Cochin, the Madras presidency, Coorg, Mysore, Bombay, Berar, and the Central Provinces is all so consumed. Formerly there was a considerable export from the ports of the western coast—Malabar, Kanara, Surat, and Broach,—but the country at present requires all the teak which its forests can produce; indeed the demand is in excess of the supply, and large quantities are imported from Burmah to Calcutta, Madras, Bombay, and other Indian ports. Small quantities are still exported from the ports of the western coast to Arabia and the coast of Africa. The chief export is from Burmah, principally from Rangoon and Maulmain. Of the other teak-producing countries, Java exports a little; there have also been exports from Saigon; and since 1882 Bankok has sent considerable quantities to Europe. But the Burmah coast is the chief source of supply at present. Rangoon has for a very long time been an important place for ship-building, teak being the chief timber used; between 1786 and 1825 111 European vessels were built at Rangoon, aggregating 35,000 tons. At the same time timber was exported, and, when the place was taken by the British in 1852, teak was the chief article of export. Maulmain became British territory at the close of the first Burmese war in 1826. At that time the place was a large fishing village, and it was mainly through the export of teak timber and the ship-building trade that it attained its present importance. From 1829 to 1841 upwards of 50,000 loads of teak timber were exported, and, in addition, 68 vessels were built during that period, aggregating 15,680 tons, and estimated to have required for their construction 24,000 loads of teak timber. The forests from which Maulmain first derived its supplies are situated on the Attaran river, a feeder of the Salwin. In 1836, however, timber began to come down from more distant forests, and in 1841 one-fourth only of the supply was brought from the Attaran forests.

The increase in the export of timber from the Burmah ports was slow at first, but has gone on rapidly since Rangoon became a British port. Since that time the timber brought to the Burmah ports has come from the following sources: (1) from the forests in the British coast provinces, Pegu and Tenasserim; (2) from the forests in the former kingdom of Burmah, floated to Rangoon down the Sitang and Irrawaddy rivers; (3) from the forests in the Shan states formerly tributary to Burmah, from the Karenni country, and from Siam, which is all floated to Maulmain by the Salwin river. Since 1856 the increase of the supply derived from these three sources has been large, as will be apparent from the following averages for the eight years 1856-57 to 1863-64 and for the two years 1883-84 and 1884-85:

	1856-7 to 1863-4.	1883-4, 1884-5.
	Loads.	Loads.
From the British coast provinces, Pegu and Tenasserim	22,675	44,228
From Burmah by Sitang and Irrawaddy rivers	6,890	66,663
From Shan states, Karenni, and Siam, by Salwin river	55,491	163,751
Total supplies	85.056	274,642
Exports by sea	76,763	153,192
Local consumption in Rangoon and Maulmain	8,293	121,450

Of the quantities exported, between 38,000 and 65,000 loads[1] have gone beyond India during this period, the balance having been sent to Calcutta, Bombay and other Indian ports. The quantities here stated do not include the timber consumed in Upper Burmah, nor that brought from the forests drained by the Menam and Mekhong rivers on the east side of the Indo-Chinese Peninsula, nor the teak produced in Java and the other islands of the Malay Archipelago, and in the extensive forests of the western peninsula of India. No data are yet available for a precise estimate; but the total amount yielded by these forests, and consumed locally or exported, appears to be not less than 500,000 loads or tons a year.

In British India a large portion of the teak-producing tracts have since 1856 been placed under conservancy management, and similar measures will doubtless be extended to the forests in Upper Burmah, now annexed to the British empire, as well as to the forests of the feudatory native states. In British India, the area of state forests demarcated in order to be permanently conserved[2] was in 1885 (in round figures) 33,000 square miles, and the teak-producing tracts included in this area may be estimated to cover about 12,000 square miles, or 7,680,000 acres. Large additions will be made to this area, especially in Upper Burmah. Of teak plantations, 12,000 acres have been formed in Burmah, 563 acres in Coorg, 3436 at Nilambur in Malabar, and about 2000 acres in other districts. There are good grounds for estimating the future yield of plantations at the rate of 50 cubic feet (one ton) per acre annually. The natural forests will in their present impoverished condition, not furnish more than one cubic foot per acre annually, but, as protection against fire is gradually extending, the proportion of teak is everywhere being increased by cultural operations in the forests, and the effect of these measures will eventually manifest itself by a considerable increase in the yield. In their present condition, the natural forests demarcated in India up to 1887 may be expected to yield 150,000 tons a year, while the produce of the plantations will eventually add 18,000 tons more. The teak forests in Java were surveyed in 1871, and their area was found to be 2280 square miles, while the plantations in that island in 1880 amounted to 24,710 acres. These figures will serve to show that, if the system commenced in India and Java is maintained, there is no reason to apprehend a diminution of the teak supply. (D. BR.)

TEAL (Old English TELE), a word of uncertain origin, but doubtless cognate with the Dutch *Taling* (formerly *Talingh* and *Telingh*), and this apparently with the Scandinavian *Atteling-And* (Brünnich, *Ornithol. Borealis*, p. 18) and *Atling*, which it seems impossible not to connect with the Scottish *Atteile* or *Atteal*, to be found in many old records, though this last word (however it be spelt) is generally used in conjunction with Teal, as if to mean a different kind of bird; and commentators have shown a marvellous inaptitude in surmising what that bird was.

The Teal is the *Anas crecca* of Linnæus, and the smallest of the European *Anatidæ*, as well as one of the most abundant and highly esteemed for the table. It breeds in many parts of the British Islands, making its nest in places very like those chosen by the Wild Duck, *A. boscas*; but there is no doubt that by far the greater number of those that are taken in decoys, or are shot, during the autumn and winter are of foreign origin. While the female presents the usual inconspicuous mottled plumage of the same sex in most species of *Anatinæ*, the male is one of the handsomest of his kind. His deep chestnut head and throat are diversified on either side by a line of buff, which, springing from the gape, runs upward to the eye, in front of which it forms a fork, one prong passing backward above and the other below, enclosing a dark glossy-green patch, and both losing themselves in the elongated feathers of the hind-head and nape. The back and sides of the body appear to be gray, an effect produced by delicate transverse pencillings of black on a dull white ground. The outer lanceolate scapulars have one-half of their webs pure white, forming a conspicuous stripe along the side of the back. The breast is of a pale salmon or peach-blossom color, each feather in front bearing a roundish dark spot, but these spots lessen in number and size lower down, and the warm tint passes into white on the belly. The tail-coverts above and below are velvety black, but those at the side are pale orange.

The Teal inhabits almost the whole of Europe and Asia,—from Iceland to Japan,—in winter visiting Northern Africa and India. It occasionally occurs on the western shores of the Atlantic; but its place in North America is taken by its representative, *A. carolinensis*, the male of which is easily to be recognized by the absence of the upper buff line on the side of the head and of the white scapular stripe, while he presents a whitish crescentic bar on the sides of the lower neck just in front of the wings.

Species more or less allied to these two are found in most other parts of the world, and among such species are some (for instance, the *A. gibberifrons* of the Australian Region and the *A. eatoni* of Kerguelen Island) in which the male wears almost the same inconspicuous plumage as the female. But the determination of the birds which should be technically considered "Teals," and belong to the subgenus *Nettium* (generally misspelt *Nettion*), as distinguished from other groups of *Anatinæ*, is a task not yet successfully attempted, and much confusion has been caused by associating with them such species as the GARGANEY (vol. x. p. 72) and its allies of the group *Querquedula*. Others again have not yet been discriminated from the WIGEONS (*q.v.*), the Pintail-Ducks, *Dafila*, or even from the typical form of *Anas* (*cf.* DUCK, vol. vii. p. 436), into each of which subgenera the Teals, *Nettium*, seem to pass without any great break. In ordinary talk "Teal" seems to stand for any Duck-like bird of small size, and in that sense the word is often applied to the members of the genus *Nettopus*, though systematists will have it, that they are properly geese. In the same loose sense the word is often applied to the two most beautiful of the Family *Anatidæ*, belonging to the genus *Æx* (commonly misspelt *Aix*)—the Carolina Duck of North America. *Æ. sponsa* (not to be confounded with the above-named *Anas carolinensis* or *Nettium carolinense*), and the Mandarin-Duck of China, *Æ. galericulata*. Hardly less showy than these are the two species of the subgenus *Eunetta*,—the Falcated Duck, *E. falcata*, and the Baikal Teal, *E. formosa*,—both from eastern Asia, but occasionally appearing in Europe. Some British authors have referred to the latter of these well-marked species certain Ducks that from time to time occur, but they are doubtless hybrids, though the secret of their parentage may be unknown; and in this way a so-called Bimaculated Duck, *Anas bimaculata*, was for many years erroneously admitted as a good species to the British list, but of late this has been properly discarded. (A. N.)

---

[1] Of the teak exported to foreign countries from India in 1883-84, 27,356 tons went to Great Britain, 8594 tons to Egypt, 2056 tons to Ceylon, 1984 tons to Japan, and 1823 tons to the Cape of Good Hope. The total quantity exported was 46,471 tons.

[2] Not including 16,000 square miles of second class reserves in the Central Provinces.

TECHNICAL EDUCATION. The special education, the object of which is to train persons in the arts and sciences that underlie the practice of some trade or profession, is technical education. Schools in which this training is provided are known as technical schools. In its widest sense, technical education embraces all kinds of instruction that have direct reference to the career a person is following or preparing to follow; but it is usual and convenient to restrict the term to the special training which helps to qualify a person to engage in some branch of productive industry. This education may consist of the explanation of the processes concerned in production, or of instruction in art or science in its relation to industry, but it may also include the acquisition of the manual skill which production necessitates. The term technical, as applied to education, arose from the necessity of finding a word to indicate the special training which was needed in consequence of the altered conditions of production during the present century. Whilst the changed conditions of production, consequent mainly on the application of steam power to machinery, demanded a special training for those who were to be engaged in productive industry, the prevalent system of education was not adapted to the requirements of these persons, and schools were wanted in which the necessary instruction could be obtained. Other circumstances resulting mainly from the application of steam power to machinery have rendered technical education necessary. Production on a large scale led to a great extension of the principle of the division of labor, in consequence of which it was found economical to keep a man constantly engaged at the same kind of work, since the more he practiced it the quicker and more skilful he became. Thus employed, the workman learned little or nothing of the process of the manufacture at which he assisted, or of other departments of the work than the particular one in which he was engaged, and his only opportunity of acquiring such knowledge was outside the workshop or factory in a technical school. The economy effected by the division of labor led to the extension of the principle to other industries than those in which machinery is largely employed. There are many trades in which manual skill is as necessary now as ever, but even in these the methods of instruction prevailing under the system of apprenticeship are now almost obsolete.

In many industries, including trades in which machinery is not as yet extensively employed, production on a large scale has increased the demand for unskilled labor, numbers of hands being required to prepare the work to be finished by a few artisans. Rapidity of execution is attained by keeping a workman at the same work, which after a time he succeeds in mechanically performing, and continues to do until some machine is invented to take his place. In most trades, as formerly practiced, the master employed a few apprentices who assisted him in his work, and who learnt from him to understand the details of their craft, so that, when the term of their apprenticeship was over, they were competent to practice as journeymen. But now the master has neither time nor opportunity to instruct young lads, and the old relation of master and apprentice is changed into that of capitalist and workman. In consequence of these altered relations between employer and employed, there is an acknowledged want of properly trained workmen in a number of trades in which skilful hand work is still needed; and in these trades a demand has arisen for technical schools, or some other substitute for apprenticeship, as a means of suitably training workmen and foremen. The ever-increasing competition in production has led to the employment, in many trades, of children to do work of a mechanical kind requiring little skill; but, whilst thus employed, these young people have little opportunity of learning those parts of their trade in which skill and special knowledge are needed; and when they are grown up, and seek higher wages, they are dismissed to make room for other children. Numbers of young men are thus thrown upon the labor market, competent to do nothing more than children's work, and to earn children's wages, and knowing no trade to which they can apply their hands. To remedy this, by creating some substitute for the old apprenticeship, is one of the objects of a system of technical education.

A complete system of technical education should provide necessary instruction for the different classes of persons engaged in productive industry. It is usual to divide these persons into three classes: (1) workmen or journeymen; (2) foremen or overseers; (3) managers or masters.

The industries in which they are employed may be grouped under four heads: (1) those involving the use of extensive machinery, such as iron and steel manufacture, machine making, the textile industries, and some of the chemical trades; (2) those which mainly require the use of hand tools, as cabinet-making, brick-work, plumbing, and tailoring; (3) those depending on artistic skill, as wood and stone carving, metal-chasing, decorative work, and industrial designing generally; (4) agriculture in all its branches. These industries will be referred to as manufactures, handicrafts, art industries, and agriculture. The foregoing classification comprises groups which necessarily, to some extent, overlap one another. Every factory contains a carpenter's and smith's shop, and handicraftsmen of group (2) are required in every manufacturing concern. Whilst the industries in which hand labor is exclusively employed are becoming fewer and fewer, there are many trades which, owing to the frequent invention of labor-saving appliances, are passing gradually from the class of handicrafts to that of manufactures. In these trades, of which watch and clock making and boot and shoe making may be taken as examples, there is still a demand for goods largely if not entirely produced by hand work. In such trades, owing to the absence of facilities for instruction in the ordinary shops, there is a want of skilled hand labor which there is an increasing difficulty in satisfying, and to supply this want technical schools of different kinds have been established. Then, again, there are many branches of manufacturing industry which greatly depend for their success upon the designer's art, and it is necessary that the industrial designer should possess a knowledge of the processes of the manufacture in which his designs will be utilized, as well as of the properties and capabilities of the material to which they will be applied. Indeed, it is the possession of this knowledge which mainly distinguishes the industrial designer from the ordinary artist. To determine the best training for such designers is one of the problems of technical education. There are many trades, too, in which the handicraftsman and the designer should be united. This is the case in such industries as wood-engraving, metal-chasing, and silversmith's work. In these and other trades the true artisan is the artist and handicraftsman combined.

In order to reconcile some of the different views which are held as to the objects of technical education, it is necessary to keep in mind the broad distinction, above referred to, between the conditions of production on a large scale, as in those industries in which goods are manufactured by the use of extensive labor-saving machinery, and in those trades in which hand work is chiefly employed. Much of the diversity of opinion regarding the objects of technical education is due to the difference of standpoint from which the problem is regarded. The volume of the trade and commerce of Britain depends mainly on the progress of its manufacturing industries. It is these which chiefly affect the exports and imports. The aim of manufacturers is to produce cheaper and better goods than can be produced by other manufacturers at home or abroad; and technical education is valuable to them, in so far as it enables them to do so. But the artisan engaged in hand industries looks to technical education for the means by which he may acquire a knowledge of the principles of his trade, which the absence of the system of apprenticeship prevents him from acquiring in the shop. Hence the artisan and the manufacturer approach the consideration of the question from different sides. To the spinner or weaver who almost exclusively employs women to tend his machinery, or to the manufacturing chemist whose workpeople are little more than laborers employed in carrying to and fro materials, knowing little or nothing of the scientific principles underlying the complicated processes in which they are engaged, the technical education of the workpeople may seem to be a matter of little moment. What such manufacturers require are the services of a few skilled engineers, artistic designers, or scientific chemists. From the manufacturer's point of view, therefore, technical instruction is not so much needed for the *hands* he employs in his work as for the *heads* that direct it. But in trades in which machinery plays a subsidiary part, technical teaching supplies the place of that instruction which, in former times, the master gave to his apprentice, and the workman looks to it to supply him with the knowledge of the principles and practice of his trade, on the acquisition of which his individual success greatly depends. In the former class of industries, technical education is needed mainly for the training of managers; in the latter, for the training of workmen. Hence has arisen a double cry,—for the teaching of art and of the higher branches of science, with a view to their application to manufacturing industry, and for the teaching of trades, and of the scientific facts which help to explain the processes and methods connected with the practice of these trades. This double cry has led to the establishment of technical universities and of trade schools.

Owing to the conditions under which manufacturing industry is now carried on, it is difficult to select competent foremen from the rank and file of the workmen. The ordinary hands gain a very limited and circumscribed acquaintance with the details of the manufacture in which they are engaged, and have little opportunity of acquiring that general knowledge of various departments of work, and of the structure of the machinery in use, which is essential to the foreman or overseer. It is in evening technical classes that this supplementary instruction, which it is the workman's interest to acquire and the master's to encourage, can be obtained. The history of invention shows how frequently important improvements in machinery are made by the workman or minder in charge of it, and adds weight to the arguments already adduced for giving technical instruction to persons of all grades employed in manufacturing industry. To these advantages of technical education, as affecting the workmen themselves as well as the progress of the industry in which they are engaged, must be added the general improvement in the character of the work produced, resulting from the superior and better-trained intelligence of those who have had the benefit of such instruction.

In order that the different classes of persons who are to be engaged in productive industry may receive a fitting preparatory training, the programme of elementary and secondary as well as of the higher education must be organized with reference to their special requirements. If the demand for technical instruction is to be fully satisfied, a great part of our existing system of education must be reconstructed, and the training provided in our several schools must be made a more fitting preparation for industrial work than it is present.

Schools in which the course of instruction is not specialized with a view to any particular industry, but is so arranged as to form a general preparation for manufacturing or other trade pursuits, are often spoken of as professional, technical, or trade schools; but such schools must be distinguished from apprenticeship schools, the object of which is to teach trades. Of the former class of schools there are excellent examples in the different countries of Europe as well as in the United States, and some few have recently been established in the United Kingdom. Of the latter class the best examples are found in France and Austria. The study of these schools, and of the means of providing fitting education for the different classes of producers, may be simplified by a statement of the following propositions:

1. The ordinary education of all persons who are likely to be engaged in productive industry should be determined by the general requirements of their future work. This proposition affects the curriculum of all schools in which different classes of producers are to be trained, *i.e.*, of primary, secondary, and higher schools, and involves the consideration of the extent to which, in such schools, modern languages, science, drawing, and manual instruction should take the place of literary and classical studies.

2. Special schools or classes should be established (*a*) for instruction in art, and in those sciences which serve to explain the processes of productive industry, including agriculture, manufactures, and engineering, as well as in the application of art and science to these departments of industry; (*b*) for the teaching of, and in certain cases for practice in, various handicrafts or trades.

3. The special schools should be adapted to the requirements of the different grades of workers, and to the different kinds of work in which they are or are likely to be engaged.

A survey of the technical schools in different countries show how these different requirements are met. Owing to the complexity of the problem, a complete or an ideal system of technical education is nowhere to be found. Schools have been established to meet local and present wants, and the greatest variety exists in the attempts that have been made to establish schools in accordance with the foregoing propositions.

1. *Workmen.*—Many attempts have been made to provide a substitute for apprenticeship, but hitherto with no great success. Two classes of workpeople have to be considered—

(1) those engaged in manufacturing industries, and (2) those engaged in handicraft industries. The education of all classes of workpeople begins in the public elementary schools; and, in view of the future occupation of the children, it may be taken for granted that primary instruction should be practical, and should include drawing and elementary science, with some amount of manual training for boys, and with needlework, cookery, and domestic economy for girls. In nearly every country of Europe, and in the United States, primary instruction includes drawing, in addition to reading, writing, and reckoning. In England this is not yet the case, drawing being taught in very few schools outside of the jurisdiction of the London school board. In France, Belgium, Holland, and Sweden handicraft instruction is generally included in the curriculum of elementary schools. Rudimentary science is also taught in nearly all the primary schools of Europe. Modelling is taught both to boys and girls in many Continental schools; and in Sweden "slojd," or elementary woodwork, in which simple and useful articles are constructed with the fewest possible tools, is taught with considerable success to children of both sexes.

In Germany and Switzerland there exists an excellent system of evening continuation schools, known as *Fortbildungs-* or *Ergänzungs-Schulen*, in which the instruction of the children who leave school before fourteen, and of those who leave at that age, is continued. In most of these schools drawing is taught with special reference to local industries. In England an attempt is being made to attract children to evening schools by means of recreative classes. These classes are intended to continue the child's general education, and to supplement it by some amount of practical teaching between the time that he leaves the elementary school and is prepared to take advantage of evening technical instruction. The training of most workpeople, and of nearly all those who are engaged in manufacturing industry, consists of (1) primary teaching in elementary schools; (2) practice in the factory or shop; (3) evening technical instruction.

In all the principal towns throughout Europe evening classes have been established for teaching drawing, painting, and designing, and the elements of science in their application to special industries. On the Continent these classes are mainly supported by the municipalities, by the chambers of commerce, by industrial or trade societies, by county boards, and in some cases by the fees of the pupils. They receive little or no support from the state. They are well attended by workpeople of all grades, who are encouraged by their employers to profit by these opportunities of instruction. In England evening technical instruction is more systematically organized than in any other country. It is under the direction of the committee of the council of education known as the Science and Art Department, and of the City and Guilds of London Institute for the advancement of technical education, an institute founded and supported by the corporation and by a large number of the livery companies of London. The department encourages instruction in pure science and in art; the institute in the application of science, and to some extent of art also, to different trades.

Both the department and the institute make grants on behalf of properly registered teachers on the results of the examination of their pupils. The directory of the department contains a detailed syllabus of the twenty-five different subjects on the teaching of which grants are paid, and in the programme of the institute are found syllabuses of instruction in the technology of fifty different trade subjects. In the evening classes organized by the department, as well as in those in connection with the institute, the workman or foreman engaged in any manufacturing industry has the opportunity, by payment of a very small fee, of studying art in all its branches, science theoretically and practically, and the technology of any particular industry. Provided his early education enables him to take advantage of this instruction, no better system has been suggested of enabling workmen, whilst earning wages at an early age, to acquire manual skill by continuous practice, and at the same time to gain a knowledge of the principles of science connected with their work and explanatory of the processes of the manufacture in which they are engaged.

For those engaged in handicraft trades this evening instruction is equally valuable, and in many parts of Europe there exist evening trade schools in which the workman is able to supplement the "sectional" practice he acquires in the shop by more general practice in other branches of his trade. In Vienna, for example, and in other parts of Austria, there are found practical evening classes for carpenters, turners, joiners, metal-workers, and others; and similar classes, some of which are subsidized by the City and Guilds Institute, have recently been established in England. Throughout Europe schools for weaving, with practical work at the loom and pattern designing, have existed for many years.

To provide a training more like the old system of apprenticeship, schools have been established in many parts of Europe which are known as professional, trade, or apprenticeship schools (*écoles professionelles, écoles des apprentis, Fachschulen*). The object is to train workmen; and the pupils, after completing their course of instruction in such a school, are supposed to have learnt a trade. The school is the substitute for the shop. In such a school the pupils have the advantage of being taught their trade systematically and leisurely, and production is made subsidiary to instruction. Under such an artificial system of production, the pupil is less likely to acquire excellence of workmanship and smartness of habit than in the mercantile shop, under the strain of severe competition. Moreover, the cost of maintenance of these schools renders it impossible to look to them as a general substitute for apprenticeship. By sending into the labor market, however, a few highly-trained workmen, who are absorbed in various works and exert a beneficial influence on other workmen, these schools serve a useful purpose. Schools of this kind have been tried with more or less success in different countries. In Paris there is the well-known École Diderot for the training of mechanics, fitters, smiths, etc.; and similar schools have been established in other parts of France. A furniture-trade school of the same category has recently been opened in Paris, and for many years a society of Christian Brethren have directed a large school in which several different trades have been taught. In this establishment, situated in the Rue Vaugirard, all the secular and general instruction is given gratuitously by the brothers, and in the several shops attached to the school skilled workmen are employed, who instruct the pupil apprentices, and utilize their labor. This system combines many of the advantages of shop work and school work, but it depends financially for its success upon the religious spirit which actuates its promoters and supporters. The Artane school, near Dublin, is conducted on somewhat similar principles, but is intended for a lower class of children. In Austria, particularly in the rural districts, there are numerous schools for the training of carpenters, joiners, turners, cabinetmakers, workers in stone and marble, in silver and other metals, etc. Schools of the same class are found in Germany, Italy, and elsewhere. It is only in certain cases, however, that apprenticeship schools can be said to satisfactorily answer the purpose for which they have been established. Where a new industry, especially in rural districts, has to be created; where decaying industries need to be revived; where machinery is superseding hand work, and, owing to the demands for ordinary hands, there is a dearth of skilled workmen; where through the effects of competition and other causes the trade is carried on under conditions in which competent workmen cannot be properly trained in the ordinary shop,—in these cases, and in various art industries, an apprenticeship school may prove to be the best means of training workmen, and of advancing particular trades. Generally, an apprenticeship school should be looked upon as a temporary expedient, as a form of relief applied at the birth or during any temporary depression of a particular industry. The proper training school for workmen is the factory or shop.

2. *Foremen.*—The foreman must be familiar with the various branches of work he is to overlook, and the training which the workman receives in the factory or shop affords him but scanty opportunities of obtaining this general knowledge. The foreman needs also a generally superior education. How then are foremen to be trained? The problem is somewhat easier than that of training workmen, because the number required is fewer. The variety of schools in Europe devoted to this purpose is very great. There are three distinct ways in which foremen are being trained.

(*a*) The evening technical classes in Britain and on the Continent offer to ambitious workmen an opportunity of acquiring a knowledge of other departments of the trade than those in which they are engaged, as well as of the scientific principles underlying their work. These classes serve the double purpose of improving the workpeople and of affording a means of discovering those who are best fitted to occupy higher posts.

(*b*) Special schools have been established for the training of foremen. There are many trade schools of this kind in which selected boys are received after leaving the elementary school. The best known are those at Châlons, Aix, Nevers, Angers, and Lille in France. These schools are intended for the training of foremen in engineering trades. They are state institutions, in which practical mechanical work in the shops is supplemented by theoretical instruction. The first of these schools was founded in 1803. The course lasts three years, and the number of students in each school must not exceed three hundred. The students spend from six to seven hours a day in the workshop, and are trained as fitters, founders, smiths, and pattern-makers. As in all such schools, salable goods are produced, but, as production is subordinated to instruction, the school does not bind itself to deliver work at a given date, and therefore does not compete with any manufacturing establishment. The students on leaving these schools are competent at once to undertake the duties of foremen, managers, or draughtsmen. At Komotau, Steyr, Klagenfurt, Ferlach, and many other places schools have been established on somewhat similar principles. In Germany there are special schools for the training of foremen in the building trade, which are chiefly frequented in the winter, and numerous schools are found in all parts of the Continent for the training of weavers. At Winterthur in Switzerland a school has been established the main purpose of which is the training of foremen. In Italy there are numerous technical institutes, the object of which is to train young men for intermediate posts in industrial works. In the United States the manual training schools, the number of which is rapidly increasing, have somewhat similar objects. In London, the Finsbury technical college of the City and Guilds of London Institute has a day department, the main purpose of which is the training of youths as foremen, works managers, etc.; but in this school, as well as in those last mentioned, the character of the instruction deviates considerably from that given in French schools, and aims rather at preparing youths to learn, than at teaching them their trade.

(*c*) A third method adopted for the training of foremen is by encouraging selected children of the ordinary elementary schools to continue their education in schools of a higher grade of a technical character. It is thought that, by developing to a higher degree the intelligence and skill of those children who show aptitude for scientific and practical work, they will be able, when they enter the shop, to learn their trades more quickly and more thoroughly, and to acquire that general knowledge of their work, and to exhibit those special aptitudes, which may qualify them for the position of foreman or manager. The education given in these schools, although having direct reference to the future career of the pupil, is disciplinary in character, and consists of the subjects of primary instruction further pursued,—of drawing, modelling, science, mathematics, and manual exercises. The curriculum is varied to some extent according to local requirements, the technology of the staple industries forming in many cases part of the instruction. Such schools, under varied forms, have been established in most Continental countries, some of the best examples of them being found in Paris, Lyons, Rheims, Rouen, and in other towns of France. The want of similar schools in Britain has been frequently pointed out. One of the oldest of these schools is the École Martinière at Lyons. The school was founded in 1820 by a bequest from Major-General Martin, who had fought against the English under Tippoo Sahib. In this school, in which the education is gratuitous, as in nearly all the higher elementary schools of France, instruction is given in drawing, modelling, chemistry, mechanics, and physics, in the working of wood and iron, and in German and English in addition to the subjects of an ordinary school education. Surveying is also taught to some of the pupils, and the instruction generally is of a very practical character. The students visit factories under the guidance of the masters, and on their return they write out full descriptions of their visits. The school hours are from seven to eleven in the morning and from one till seven in the afternoon. The boys from this school rapidly obtain places in the commercial and industrial houses of Lyons, and many of them, after a time, succeed in obtaining high positions. A very similar school, on more modern lines, has been established at Rheims, and is accommodated in a building especially adapted to the purpose. In this school instruction is directed towards the staple industries of the district, namely, weaving, dyeing, and engineering. There are many other similar schools in France, the object of which is to give the children of artisans and small shopkeepers a higher practical education in order to fit them to occupy the posts of foremen, overseers, and superior clerks in manufacturing and commercial firms. A large number of poor children showing talent are selected from the primary schools and receive scholarships; and the objection sometimes urged against the establishment of higher elementary schools,—that the better classes only are able to benefit by them—is thus obviated. In Germany the real-schools in which Latin is not taught, known as *Ohnelatein Realschulen*, have very nearly the same objects as the higher elementary schools of France. The instruction in these German schools is not yet so practical as in the schools of France. Drawing is always well taught, and the schools generally contain good chemical laboratories, as well as collections of physical apparatus and museums. From the children of these schools the ranks of foremen are largely recruited. They receive no special trade instruction, but the general training is so arranged as to qualify them for higher posts in industrial works. The cost of this higher education seldom exceeds £3 [$14.58] per annum. In Bavaria it is two shillings [49c.] a month. In most of these schools, as well as in the chief intermediate commercial schools, the exit certificate exempts a lad from two of the three years' compulsory military service, and this regulation, to which nothing corresponds in England, is an incentive to parents to allow their children to receive higher instruction, which operates very forcibly in largely increasing the number of well-educated youths in Germany. In these opportunities for higher education England is still very deficient, and the complaint is generally heard of the difficulties of obtaining competent foremen.

3. *Masters.*—The best special schools for the training of future masters, managers, engineers, manufacturers, and industrial chemists are in Germany and are known as technical high schools or polytechnic schools. Schools of a similar character are found in other countries, and in England the facilities for higher technical education have within the last few years greatly improved.

In Germany the polytechnic or *technische Hochschule* is an institution of university type in which the education has special reference to industrial purposes. In many respects the teaching coincides with that given in the universities. The chief distinction consists in the arrangement of courses of instruction in the several departments, in the admission of students having a non-classical preliminary training, and in the absence of certain faculties found in the university and the addition of others. It is not correct to say that the polytechnic is a professional school as distinguished from the university; for the faculties of law, medicine, and theology give to the university as distinctly a professional character as the faculty of engineering gives to the polytechnic. Nor can it be said that the scientific studies at the universities are less practical than at the polytechnic. For, whilst workshops for instruction in the use of tools are found in very few of the polytechnic schools, the laboratories, for the practical study of chemistry and physics, are perhaps better fitted and under more eminent professors at some of the German universities than at the polytechnic schools. At the same time, engineers of every description, architects, and builders, besides a great number of manufacturing chemists, find in the polytechnic the scientific and technical training which the lawyer or physician, and in many cases the industrial chemist, seeks in the university.

In some of the large cities—in Berlin, Vienna, and Munich, for instance—the university and polytechnic coexist; and in certain cases, in which a very special training is required to fit a youth for his career, the German student, after spending three or four years at a polytechnic school, passes on to another institution, such as a dyeing school, in which his studies are further specialized with a view to his future work.

Taking the technical high school of Munich as a type of other similar institutions, we find the cost of the building and of the various collections it contains to have amounted to nearly £200,000 [$972,000], and the annual cost of maintenance to be about £20,000 [$97,200]. The institution consists of six schools: (1) the general; (2) the civil engineering; (3) the building; (4) the mechanical engineering; (5) the industrial chemical; and (6) the agricultural. A department for electrical technology is now being built. In other institutions there are architectural, pharmaceutical, and mining schools. The programme of the Munich school gives a list of about 180 different courses of instruction distributed over the several departments. A separate professor is engaged to lecture on that particular subject with which he is specially conversant, and the number of such professors attached to a polytechnic school is very large. In the engineering department there are six or seven distinct courses of lectures under the direction of thirteen professors. The largest and most recently constructed of all these institutions is the polytechnic school of Berlin, which was completed in 1884 at a cost of about £450,000 [$2,187,000]. In France the institutions in which the highest technical instruction is given are concentrated in the capital. There are a large number of provincial colleges where the education is somewhat more practical, but where the mathematical and scientific teaching is not carried to so high a point (the École Centrale at Lyons, the École des Mineurs at St. Étienne, and the Institut du Nord at Lille, etc.). The École Centrale of Paris, in which the majority of French engineers who are not employed in the Government service are trained, is a rare instance of an institution for higher technical instruction which is self-supporting and independent of Government aid.

In Switzerland the federal polytechnic of Zurich is similar to the polytechnic schools of Germany and Austria. Italy has three superior technical institutes,—one at Milan, one at Turin, and one at Naples, in which technical education is given on the same lines as in German polytechnic schools. Holland has an excellent institution at Delft, which was opened in 1864; and in Russia the imperial technical school at Moscow is a high-class engineering school, in which the theoretical studies are supplemented, to a greater extent than in the German schools, by workshop practice.

In some of the German schools the fees charged vary according to the number of lectures and the number of hours of practical work which the student takes per week. Thus at Munich the entrance fee for each student is 10s. [$2.43], and the lecture fee is 2s. 6d. [60¾c.] for each hour's lecture per week, including the use of materials. At Zurich the cost of a student in a chemical department, including laboratory practice, does not exceed £12 [$58.32] per annum, and in other departments it does not exceed £4 [$19.44] per annum. At Delft the student pays about £16 [$77.76] per annum for a complete course.

In England there is a growing tendency to associate technical with university education. This is mainly owing to the fact that the colleges which have recently been established to give university education are poorly endowed, and have found it necessary to attract students by meeting the increasing demand for technical instruction. Most of the provincial colleges may indeed be regarded as technical schools with a literary side. In order that they may provide university education in addition to sound technical instruction, it is necessary that they should be placed on a sound and satisfactory footing by means of state endowment. Of the more recently erected English colleges, the Owens College at Manchester is the most important, combining the faculties of a German university with those of a polytechnic school. The Yorkshire College, Leeds, possesses a special school for the teaching of weaving and dyeing. Other somewhat similar institutions are found in Birmingham, Newcastle, Sheffield, Nottingham, Dundee, Cardiff, and elsewhere. The university of Edinburgh has a good school of chemistry, physics, and engineering, and the university of Glasgow has been long distinguished for the excellence of its physical laboratories. In University College and King's College, London, the metropolis possesses two institutions each of which may be likened to a university and a polytechnic combined. In the university of Cambridge there are mechanical workshops in connection with the chair of engineering. The Royal School of Mines and the normal schools of science and art in South Kensington are the only technical institutions in England supported by state aid. The central institution in London has more in common with the German polytechnic school than any other institution in Britain. This school is designed for the technical teaching of engineers, architects, master builders, and industrial chemists. It was built at a cost of £100,000 [$486,000], and is maintained by an annual grant from the City and Guilds of London Institute of £10,000 [$48,600], in addition to the students' fees.

Such is a brief outline of the means provided for the technical education of masters in different parts of Europe. It will be seen from the foregoing statement that efforts are now being made to bring Britain more nearly on a level with other countries in the provision of those kinds of instruction which are best adapted to the different classes of producers. But as yet only a beginning has been made, and in England technical students can be counted by hundreds, whilst those of Germany are numbered by thousands.

For further information the reader is referred to the *Report* of the royal commissioners on technical instruction, published in 1884. (P. M*.)

TEGEA, one of the chief cities of Arcadia, of which its territory occupied the southeastern corner, being bounded on the S. by Laconia, on the E. by Cynuria and Argolis, on the N. by the territory of Mantinea, and on the W. by Mænalia. Its legendary founder was Tegeates, son of Lycaon. Like many other cities of ancient Greece, Tegea was formed by the union of a population which had previously lived dispersed in villages. The people were divided into four tribes,—the Clareotis, Hippothœtis, Apolloniatis, and Athaneatis. Tegea offered a stubborn resistance to the encroachments of Lacedæmon, and on more than one occasion defeated its ambitious neighbor. About 560 B.C., however, the Lacedæmonians found the bones of Orestes in Tegea and conveyed them to Sparta; and henceforward Spartan valor, backed by this powerful fetich, proved too much for the merely carnal weapons of Tegea. At Platæa (479 B.C.), 3000 Tegeans fought the good fight of freedom, and were the first to enter the breach which the Athenians had made in the Persian redoubt. Between the Persian and Peloponnesian Wars hostilities again broke out between Tegea and Sparta, in the course of which Tegea was twice defeated. However, in the Peloponnesian War (431–404), and afterwards in the Corinthian War (395–387), Tegea sided with Sparta. But after the battle of Leuctra (371), when the star of Sparta began to decline, Tegea concluded an alliance with the victorious Thebans, and fought on their side against Sparta at the great battle of Mantinea (362). In the Macedonian period Tegea joined the Ætolian League, but Cleomenes, king of Sparta, having won it over to his side, the city was besieged and taken by Antigonus Doson, king of Macedonia, the ally of the Achæan League (222). In 218 the city was retaken, except the acropolis, by the Lacedæmonians under Lycurgus. After the defeat of Machanidas, tyrant of Sparta, by Philopœmen in 207, Tegea passed into the hands of the Achæan League. In the time of Strabo it was the only town of any importance in Arcadia. In the 2d century it was visited by Pausanias, who has left a fairly full description of it (viii. 45–53).

Of its buildings much the most famous was the great temple of Athene Alea, which had often afforded sanctuary to fugitives from Sparta. The old temple was burned down in 394 B.C., and Pausanias speaks of the newer temple as by far the finest and largest in the Peloponesus (that of Zeus at Olympia, however, occupied nearly double the area). The architect was Scopas; and, as the recent German excavations have proved, the temple was a Doric peripteros, with six columns at each end and fourteen at each side. Of the columns which Pausanias mentions in addition to the Doric, the Corinthian may have stood in the pronaos and posticum, the Ionic in "the interior of the temple" (for ἐκτός we should probably read ἐντός in Pausanias, viii. 45, 5). The ancient image of Athene Alea was carried off by Augustus, and placed at the entrance to his new forum at Rome. The statues of Æsculapius and Health, which in Pausanias's time stood on the two sides of the image of the goddess at Tegea, were by Scopas. On the front pediment of the temple was sculptured the hunt of the Calydonian boar, on the back pediment the combat between Telephus and Achilles. Some fragments of these pedimental sculptures (comprising the head of the boar and two human heads, one helmeted) have been discovered; and, as they are the only existing sculptures which can be referred with some certainty to the hand of Scopas himself, they are of the highest importance for the history of art. The site of the temple, at the modern village of Piali, was partially excavated under the auspices of the German archæological institute in 1879 and 1882. It appears that the foundations of the temple measured 49.90 metres (nearly 164 feet) by 21.30 (70 feet). As Tegea stood on a plain surrounded by mountains and liable to inundations, its site has been covered by an alluvial soil which has been favorable to the preservation of the ruins, and a thorough excavation might yield important results.

TEGNÉR, Esaias (1782–1846), the most celebrated of Swedish writers, was born November 13, 1782, at Kyrkerud in Wermland. His father was a pastor, and his grandparents on both sides were peasants. His father, whose name had been Esaias Lucasson, took the surname of Tegnerus—altered by his fifth son, the poet, to Tegnér—from the hamlet of Tegnaby in Småland, where he was born. In 1799 Tegnér, hitherto educated in the country, entered the university of Lund, where he graduated in philosophy in 1802, and continued as tutor until 1810, when he was elected Greek lecturer. In 1812, he was named professor, and continued to work as a lecturer in Lund until 1824, when he was made bishop of Wexiö. At Wexio he remained until his death, twenty-two years later. Tegnér's early poems have little merit. He was comparatively slow in development. His first great success was a dithyrambic war-song for the army of 1808, which stirred every Swedish heart. In 1811 his patriotic poem *Svea* won the great prize of the Swedish Academy, and made him famous. In the same year was founded in Stockholm the Gothic League (*Götiska förbundet*), a sort of club of young and patriotic men of letters, of whom Tegnér quickly became the chief. The club published a magazine, entitled *Iduna*, in which it printed a great deal of excellent poetry, and ventilated its views, particularly as regards the study of old Icelandic literature and history. Tegnér, Geijer, Afzelius, and Nicander became the most famous members of the Gothic League. Of the very numerous poems written by Tegnér in the little room at Lund which is now shown to visitors as the Tegnér museum, the majority are short, and even occasional lyrics. His celebrated *Song to the Sun* dates from 1817. He completed three poems of a more ambitious character, on which his fame chiefly rests. Of these, two, the romance of *Axel* and the delicately-chiselled idyl of *Nattvardsbarnen* ("The First Communion," 1820), translated by Longfellow, takes a secondary place in comparison with Tegnér's masterpiece, of world-wide fame. In 1820 he published in *Iduna* certain fragments of an epic or cycle of epical pieces, on which he was then working, *Frithiofssaga* or the Story of Frithiof. In 1822 he published five more cantos, and in 1825 the entire poem. Before it was completed it was famous throughout Europe; the aged Goethe took up his pen to commend to his countrymen this "alte, kräftige, gigantisch-barbarische Dichtart," and desired Amelia von Imhoff to translate it into German. This romantic paraphrase of an ancient saga was composed in twenty-four cantos, all differing in verse form, modelled somewhat, it is only fair to say, on an earlier Danish masterpiece, the *Helge* of Oehlenschläger. *Frithiofssaga* is the best known of all Swedish productions; it is said to have been translated nineteen times into English, eighteen times into German, and once at least into every European language. It is far from satisfying the demands of more recent antiquarian research, but it still is allowed to give the freshest existing impression, in imaginative form, of life in early Scandinavia. In later years Tegnér began, but left unfinished, two important epical poems, *Gerda* and *Kronbruden*. The period of the publication of *Frithiofssaga* (1825) was the critical epoch of his career. It made him one of the most famous poets of Europe; it transferred him from his study in Lund to the bishop's palace in Wexiö; it marked the first breakdown of his health, which had hitherto been excellent; and it witnessed a singular moral crisis in the inner history of the poet, about which much has been written, but of which little is known. Tegnér was at this time passionately in love with a certain beautiful Euphrosyne Palm, the wife of a town-councillor in Lund, and this unfortunate passion, while it inspired much of his finest poetry, turned the poet's blood to gall. From this time forward the heartlessness of woman is one of Tegnér's principal themes. It is a remarkable sign of the condition of Sweden at that time that a man not in holy orders, and so little in possession of the religious temperament as Tegnér, should be offered and should accept a bishop's crozier. He did not hesitate in accepting it; it was a great honor; he was poor; and he was anxious to get away from Lund. No sooner, however, had he begun to study for his new duties than he began to regret the step he had taken. It was nevertheless too late to go back, and Tegnér made a respectable bishop as long as his health lasted. But he became moody and melancholy; as early as 1836 he complained of fiery heats in his brain, and in 1840, during a visit to Stockholm, he suddenly became insane. He was sent to an asylum in Schleswig, and early in 1841 he was cured, and able to return to Wexiö. It was during his convalescence in Schleswig that he wrote *Kronbruden*. He wrote no more of importance; in 1843 he had a stroke of apoplexy, and on the 2d of November, 1846, he died in Wexiö. From 1819 he had been a member of the Swedish Academy, where he was succeeded by his biographer and best imitator Böttiger. In prose Tegnér wrote letters, which have been collected, and which are considered the best of their kind in the Swedish language. As a poet he will scarcely be preferred to Bellman or to Runeberg by Swedish verse amateurs, but he still exceeds these and all other writers in popularity.

TEHERAN, or, more properly, **TEHRAN** (lat. 35° 40′ N., long. 51° 25′ E.), for about a century the recognized capital of Persia, has little to distinguish it, in general outward appearance, from other large cities of the country, though in quite recent years Parisian streets or boulevards, and even Western architecture for single houses, in the midst of mud-brick palaces or plain mud hovels, have been incongruously introduced. Formerly a kind of polygon some 4 miles in circumference—with its mean "shahr panah" or wall, its clumsy and uneven ditch, and its six gates, two facing north, two south, one east, and one west,—Teheran has now been extended to an outer ditch and wall, thrown out on each side beyond the ancient limit. The bazaars are good, though hardly of the first class; the caravanserais deserve honorable mention; and the telegraph and arsenal are respectable institutions. The streets are for the most part narrow and wretchedly paved. The "Ark," or citadel, contains the royal and better description of public buildings, and connecting its encircling wall with the city gates are four principal thoroughfares, of which the parallel avenues from the Násiriya and Daulat entrances are the more notable. Between these two gates, in a parallelogram extending from one to the other and including both, is the gas-lighted Tôp Maidan, or "Place des Canons," in the centre of which is a large reservoir. European professors are to be found in the king's college, where some 250 students, more or less, are taught mathematics, engineering, military tactics, music, telegraphy, painting, together with the Arabic, English, French, and Russian languages. Among the not very remarkable mosques—to some of which *madrasahs*, or colleges, are attached—may be specially mentioned the Masjid-i-Shah, or king's mosque, with its handsome enamelled front, and the Masjid-i-Mádar-i-Shah, or mosque of the king's mother. Water is freely supplied to the town by means of the underground canals, or *kanáts*, from the near mountain ranges. Public baths abound, but the Europeans use those of the Armenian and not of the Mohammedan community. The British legation stands in a handsome garden of great size, in which are placed the houses of the secretaries, which resemble English villas. In the summer season the representatives of Western powers and other Europeans move out to the slope of the mountain range north of Teheran,—the British residents to Gulhak, a village about 7 miles from the city. A prominent feature in the landscape at Gulhak and the neighboring summer quarters, as at Teheran itself, is Demavend, the noblest and most graceful of Persian mountains.

The present population of Teheran may be taken at 160,000 at most. According to a late authority (Bassett, 1887) the European inhabitants are reckoned at about 100 only; the Jews number some 2500; and there are 150 Gabrs or Parsis, a sorry remnant of the old fire-worshippers. In 1872 there were said to be 1000 Armenians, mainly traders and artisans. In 1872 there were but four legations in Teheran—those of England, France, Russia, and Turkey. Since that year representatives have been added from Holland, Austria, Germany, and the United States. The French have summer quarters at Tejrísh and the Russians at Zargandah, at no great distance from the English Gulhak.

Morier supposes Teheran to be the Tahors of the Theodosian Tables, and recognizes it also in the account of the journey of the Castilian ambassadors to Timur. Porter, too, relates that in 1637 the secretary of the Holstein ambassadors mentions Teheran as "one of the towns which enjoy the privilege of maintaining no soldiers." Again, in the 17th century, it was visited by Pietro della Valle and by Sir Thomas Herbert,—the latter spelling it "Tyroan." Most writers affirm that Teheran, though not of recent origin, can barely be held of repute till Agha Muhammad made it his residence in about 1788, taking to himself the title of shah, as first of the Kajar kings, in 1796. Yet there is evidence that in the previous century it was a royal resort, if nothing more, in Herbert's statement that "the Toune is most beautified by a vast garden of the kings, succinct with a great towered mud-wall larger than the circuit of the city." Du Pré (who visited it in 1808) states that it had been pillaged and nearly destroyed by the Afghans,—evidently at their invasion of Persia in 1728. Since Agha Muhammad's time Teheran has been the usual seat of the Kajar dynasty, a circumstance to be attributed to the political advantages of its geographical position.

See, besides the authorities cited, *Telegraph and Travel* (1874); Dr. Wills's *Land of the Lion and Sun* (1883); and Mr. Bassett's *Land of the Imáms* (1887).

TEHUANTEPEC, an isthmus in Mexico, comprising the western extremities of the states of Vera Cruz and Oajaca, and limited eastwards by the states of Tabasco and Chiapas, thus lying between 16° and 18° N. lat. and 94° and 95° W. long. Between the Bay of Campeche on the north or Atlantic side and that of Tehuantepec on the south or Pacific side the distance in a bee line is only 125 miles. Here also the Sierra Madre falls rapidly from over 5000 feet in Chiapas to about 730 feet in the ridge skirting the Pacific coast, and leaving the rest of this district somewhat level, with a rise from the Atlantic of not more than 60 feet in the mile except at the Chivela Pass, where for 8 miles the gradients are about 116 feet per mile.

This favorable condition of the relief, combined with a relatively healthy climate subject only to dangerous insect pests in summer, has naturally attracted attention to the Tehuantepec isthmus, as offering peculiar advantages for interoceanic communication either by a navigable canal, a railway, or a ship railway. A first concession was made in 1841 by the Mexican Government to Don José de Garay, who had the land surveyed with a view to a canal, but who, after the war with the United States, surrendered his rights to Mr. P. A. Hargous of New York. The company then organized to give effect to the Garay grant caused a fresh survey for a railway to be made in 1851, under the direction of the late General J. G. Barnard. But nothing came of this or of another railway project in 1857, when a third survey was executed, under the direction of Col. W. H. Sidell. Then the "Tehuantepec Railway Company," formed in 1870 in New York, and reorganized in 1879, obtained a concession from the Mexican Government to construct the "Tehuantepec Railway;" but, after a few miles were made, the work was suspended, and in 1882 the Government contracted with private individuals for the completion of the line, which was to be 190 miles long, and to run from the mouth of the Goatzacoalcos (Coatzacoalcos) river on the Atlantic to the port of Salina Cruz on the Pacific. The work was carried to Minatitlan, a distance of 25 miles, in 1884, and was to have been completed in 1885; but since then operations appear to have been suspended for want of means. A Tehuantepec ship railway is also projected, as it is expected that most of the trade between the Atlantic and Pacific coasts of the United States will be attracted to this route, which shortens the distance between New York and San Francisco by 1477 miles, and between New Orleans and the same place by 2334 miles, as compared with that by the Panama railway and future canal.

Tehuantepec, the town which gives its name to the isthmus, bay, and neighboring lagoon, stands on the river Tehuantepec, 15 miles above its mouth on the Pacific, where it develops a shallow and somewhat exposed harbor. Of the population, estimated at 14,000, a large number are civilized and industrious Indians engaged in cotton-weaving and on the salt-works. Indigo is grown in the district, and there are productive pearl-fisheries in the bay. Amongst the exports are cochineal and a purple dye extracted from a shellfish abounding on the coast.

TEIGNMOUTH, a seaport and market town of England, in Devonshire, consisting of the parishes of East and West Teignmouth, and situated on the English Channel, at the mouth of the Teign and on the Great Western Railway, 14 miles south of Exeter and 209 west-southwest of London. It is somewhat irregularly built, partly on a projecting peninsula and partly on the acclivities rising behind the river. The Teign is crossed by a bridge 1671 feet in length, built of wood and iron in 1824. St. Michael's church, in East Teignmouth, erected in 1822-23 in the Decorated style, was enlarged in 1875. The other buildings include St. Scholastica's abbey (erected for Benedictine nuns in 1862), the East Devon and Teignmouth club-house, the mechanics' institute (1840), the temperance hall (1879), the sailors' home (1881), the baths (1883), and the public market (1883). There are two commodious quays and a pier 600 feet in length. Fine pipe and potters' clay (from Kingsteignton) is shipped to Staffordshire. Coal and culm are imported, and there is also a trade with Newfoundland. Fishing is extensively carried on. The town, which is not incorporated, was formerly governed by portreeves. It now forms an urban sanitary district, which was extended on 29th September, 1881. The population of the former area (1238 acres) in 1871 was 6751, and in 1881 it was 7120; that of the extended area (2347 acres) in 1881 was 8496.

Teignmouth is of very ancient origin. It received a grant of a market from Henry III. East Teignmouth was formerly called Teignmouth Regis, and West Teignmouth, Teignmouth Episcopi,—the manor having belonged to the see of Exeter until alienated by Bishop Vesey. Teignmouth was burned by French pirates in 1340, and was again devastated by the French on 26th June, 1690.

TEINDS. See TITHES.

TELEGRAPH.[1]

TELEGRAPH (from *τῆλε* and *γράφω*) signifies an instrument to write at a distance. The term is specifically applied to apparatus for communicating intelligence to a distance in unwritten signs addressed to the eye or ear, and has only recently had application to those wonderful combinations of inanimate matter which literally write at a distance the intelligence committed to them. The chief object of the present article is to explain the principles and practice of the electric telegraph, and we shall allude to other telegraphic systems only to illustrate the general principles of signalling.

Signalling generally.

A word expressing an idea may, according to a prearranged plan of signalling, be communicated by voice, by trumpet calls, by gun fire, by gesture or dumb signs, by lamp signals, by flags, by semaphore, or by electric telegraph. The simplest system of word-signalling hitherto practiced is that of the nautical flag telegraph, in which each hoist represents a word by a combination of four flags in four distinct positions (see SIGNALS, NAVAL). If n denote the number of flags, supposed all different, out of which the four to be sent up may be selected, the number of different ideas which can be expressed by a single hoist is $n(n-1)(n-2)(n-3)$, since there are n varieties out of which the flag for each of the four positions may be independently chosen. To commit to memory so great a number of combinations, which amount to 358,800 if $n=26$, would be a vain effort; the operators on each side must therefore have constant recourse to a dictionary, or code, as it is called. For the sake of convenient reference each flag is called by the name of a letter of the alphabet, and all that the operator has to bear in mind is the letter by which each flag is designated. Sometimes the words to be expressed are spelled out by means of the flags as in ordinary language; but, as in most words there are more than four letters, as scarcely any two consecutive words are spelled with four or less than four letters, and as more than four flags at a time cannot be conveniently used, the system of alphabetic signalling frequently requires the use of two hoists for a word, and scarcely ever has the advantage of expressing two words by one hoist. It is therefore much more tedious than code signalling in the nautical telegraph.

---

[1] [Some account of American contributions to telegraphy will be found in the Appendix to this volume under the title TELEGRAPHS.]

In point of simplicity spoken words may be considered as almost on a par with the nautical telegraph, since each word is in reality spoken and heard almost as a single utterance. Next in order comes the system of spelling out words letter by letter, in which—instead of, as in the nautical telegraph, 358,800 single symbols to express the same number of ideas—26 distinct symbols are used to express by their combinations any number whatever of distinct ideas. Next again to this may be ranked the system by which several distinct successive signals are used to express a letter, and letters thus communicated by compound signals are combined into words according to the ordinary method of language. It is to this last class that nearly all practical systems of electro-telegraphic signalling belong. But some of the earliest and latest proposals for electric telegraphs are founded on the idea of making a single signal represent a single letter of the alphabet; as instances we may name those early forms in which separate conductors were used for the different letters; a method suggested by Professor W. Thomson[1] in 1858 in which different strengths of current were to be employed to indicate the letters; and the various forms of printing telegraph now in use.

I. HISTORICAL SKETCH OF EARLY TELEGRAPHS.

Early forms.

Although the history of practical electric telegraphy does not include a period of more than half a century, the idea of using electricity for telegraphic purposes is much older. It was suggested again and again as each new discovery in electricity and magnetism seemed to render it more feasible. Thus the discovery of Stephen Gray and of Wheeler that the electrical influence of a charged Leyden jar may be conveyed to a distance by means of an insulated wire gave rise to various proposals, of which perhaps the earliest was that in an anonymous letter[2] to the *Scots Magazine* (vol. xv. p. 73, 1753), in which the use of as many insulated conductors as there are letters in the alphabet was suggested. Each wire was to be used for the transmission of one letter only, and the message was to be sent by charging the proper wires in succession and received by observing the movements of small pieces of paper marked with the letters of the alphabet and placed under the ends of the wires. A very interesting modification was also proposed in the same letter, viz., to attach to the end of each wire a small light ball which when charged would be attracted towards an adjacent bell and strike it. Some twenty years later Le Sage proposed a similar method, in which each conductor was to be attached to a pith ball electroscope. An important advance on this was proposed in 1797 by Lomond,[3] who used only one line of wire and an alphabet of motions. Besides these we have in the same period the spark telegraph of Reiser, of Don Silva, and of Cavallo, the pith ball telegraph of Ronalds, and several others. Next came the discovery of Galvani and of Volta, and as a consequence a fresh set of proposals, in which voltaic electricity was to be used. The discovery by Nicholson and Carlisle of the decomposition of water and the subsequent researches of Davy on the decomposition of the solutions of salts by the voltaic current was turned to account in the water voltameter telegraph of Sömmering and the modification of it proposed by Schweigger, and in a similar method proposed by Coxe, in which a solution of salts was substituted for water. Then came the discovery by Romagnesi and by Oersted of the action of the galvanic current on a magnet. The application of this to telegraphic purposes was suggested by Laplace and taken up by Ampère, and afterwards by Triboaillet and by Schilling, whose work forms the foundation of much of modern telegraphy. Faraday's discovery of the induced current produced by passing a magnet through a helix of wire forming part of a closed circuit was laid hold of in the telegraph of Gauss and Weber, and this application was at the request of Gauss taken up by Steinheil, who brought it to considerable perfection. Steinheil communicated to the Göttingen Academy of Sciences in September, 1838, an account of his telegraph, which had been constructed about the middle of the preceding year. The currents were produced by a magneto-electric machine resembling that of Clarke. The receiving apparatus consisted of a multiplier, in the centre of which were pivoted one or two magnetic needles, which either indicated the message by the movement of an index or by striking two bells of different tone or recorded it by making ink dots on a ribbon of paper. Among other workers about this time we may mention Masson, Bréguet, Davy, Deval, Billon, Soudalot, and Vorsselman, who proposed to use the physiological effects of electricity in working an electric telegraph.[4]

Steinheil appears to have been anticipated in the matter of a recording telegraph by Morse of America, who in 1835 constructed a rude working model of an instrument; this within a few years was so perfected that with some modification in detail it has been largely used ever since (see below). In 1836 Cooke, to whom the idea appears to have been suggested by Schilling's method, invented a telegraph in which an alphabet was worked out by the single and combined movement of three needles. Subsequently, in conjunction with Wheatstone, he introduced another form, in which five vertical index needles, each worked by a separate multiplier, were made to point out the letters on a dial. Two needles were acted upon at the same time, and the letter at the point of intersection of the direction of the indexes was read. This telegraph required six wires, and was shortly afterwards displaced by the single-needle system, still to a large extent used on railway and other less important circuits. The single-needle instrument is a vertical needle galvanoscope worked by a battery and reversing key, the motions to right and left of one end of the index corresponding to the dashes and dots of the Morse alphabet. To increase the speed of working, two single-needle instruments were sometimes used (double-needle telegraph). This system required two lines of wire, and, along with all multiple-wire systems, soon passed out of use. Similar instruments to the single and double needle ones of Cooke and Wheatstone were about the same time invented by the Rev. H. Highton and his brother Edward Highton, and were used for a considerable time on some of the railway lines in England. Another series of instruments, introduced by Cooke and Wheatstone in 1840, and generally known as "Wheatstone's step-by-step letter-showing" or "A B C instruments" were worked out with great ingenuity of detail by Wheatstone in Great Britian and by Bréguet and others in France. They are still largely used for private wires, but are being rapidly displaced by the telephone.[1] Wheatstone also described and to some extent worked out an interesting modification of his step-by-step instrument, the object of which was to produce a letter-printing telegraph. But it never came into use; some years later, however, an instrument embodying the same principle, although differing greatly in mechanical detail, was brought into use by Royal E. House of Vermont, U.S., and was very successfully worked on some of the American telegraph lines till 1860, after which it was gradually displaced by the Phelps combination telegraph. The House instrument is not now in use, but various modifications of it are still employed for private lines and for stock telegraphs, such as Calahan's and the universal stock telegraphs, Phelps's stock printer, Gray's automatic printer for private lines, Siemens's and Phelps's automatic type printers, etc. (see *infra*, pp. 129–130).

[1] See his *Mathematical and Physical Papers*, vol. ii. p. 105.

[2] From correspondence found among Sir David Brewster's papers after his death it seems highly probable that the writer of this letter, which was signed "C. M.," was Charles Morrison, a surgeon and a native of Greenock, but at that time resident in Renfrew.

[3] See Arthur Young, *Travels in France*, p. 8.

[4] The reader interested in the early history of the electric telegraph may consult Edward Highton, *The Electric Telegraph*, London, 1852; Moigno, *Traité de Télégraphie Électrique*, Paris, 1849; and Sabine, *History of the Electric Telegraph*, London, 1869.

II. GENERAL DESCRIPTION OF ELECTRIC TELEGRAPHS FOR LAND AND SEA.

Essential apparatus.

The first requisite for electro-telegraphic communication between two localities is an insulated conductor extending from one to the other. This, with proper apparatus for originating electric currents at one end and for discovering the effects produced by them at the other end, constitutes an electric telegraph.[2] Faraday's term "electrode," literally a way for electricity to travel along, might be well applied to designate the insulated conductor along which the electric messenger is dispatched. It is, however, more commonly and familiarly called "the wire" or "the line."

The apparatus for generating the electric action at one end is commonly called the *transmitting apparatus* or *instrument*, or the *sending apparatus* or *instrument*, or sometimes simply the *transmitter* or *sender*. The apparatus used at the other end of the line to render the effects of this action perceptible to any of the senses—eye, ear, or taste, all of which have been used in actual telegraphic signalling—is called the *receiving apparatus* or *instrument*.

Over-ground lines.

In the aerial or overground system of land telegraphs the main line consists generally of a "galvanized" iron wire from one-sixth to a quarter of an inch in diameter, stretched through the air from pole to pole, at a sufficient height above the ground for security. The supports or insulators, as they are called, by which it is attached to the poles are of very different form and arrangement in different telegraphs, but consist essentially of a stem of glass, porcelain, coarse earthenware, or other non-conducting substance, protected by an overhanging screen or roof. One end of the stem is firmly attached to the pole, and the other bears the wire. The best idea of a single telegraphic insulator may be got from a common umbrella, with its stem of insulating substance attached upright to the top of a pole and bearing the wire supported in a notch on the top outside. The umbrella may be either of the same substance as the stem—all glass or all glazed earthenware, for instance—or of a stronger material, such as iron, with an insulating stem fitted to it to support it below. Very good insulators may be made of continuous glass; but well-glazed porcelain is more generally used, or rather earthenware, which is cheaper, less brittle, and insulates well as long as the glazing is sufficent to prevent the porous substance within from absorbing moisture.

One of the best forms—Varley's double cup insulator—is shown in Fig. 1. It consists of two distinct cups (*c*, C), which are moulded and fired separately, and afterwards cemented together. The double cup gives great security against loss of insulation due to cracks extending through the insulator, and also gives a high surface insulation. An iron bolt (*b*) cemented into the centre of the inner cup is used for fixing the insulator to the pole or bracket.

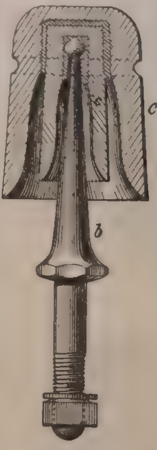

FIG. 1.—Varley's double cup insulator, one-fourth full size.

Under-ground lines.

In the underground system the main line generally consists of a copper wire, or a thin strand of copper wires, covered with a continuous coating of gutta percha, india-rubber, or some equivalent insulating substance, served with tarred tape and enclosed in earthenware, iron, or lead pipes laid below the surface of the ground. This system is largely used for street and tunnel work, and to a considerable extent, especially in Germany, for ordinary lines. Each tube generally contains a number of wires, which are either laid up into a cable and covered with a serving of tarred tape or hemp before being drawn into the tube, or—as is more commonly the case in the United Kingdom—simply laid together in a parallel group and tied at intervals with binders, which are removed as the wires are drawn into the tube. On some long underground lines in Germany the insulated wires are laid up into a cable, served with jute or hemp, and sheathed with a continuous covering of iron wires, precisely similar to the submarine cables described below. The cable is laid in a deep trench and coated with bitumen. This form of cable is easily laid, and if properly manufactured is likely to be very durable.

Sub-marine cables.

Submarine Cables.—A submarine cable (Figs. 2–4), as usually manufactured at present, consists of a core *a* in the centre of which is a strand of copper wires varying in weight for different cables between 70 and 400 ℔ to the mile. The stranded form was suggested by Prof. W. Thomson at a meeting of the Philosophical Society of Glasgow in 1854, because its greater flexibility renders it less likely to damage the insulating envelope during the manipulation of the cable. The central conductor is covered with several continuous coatings of gutta percha, the total weight of which also varies between 70 and 400 ℔ to the mile. With a light core the weight of the gutta percha generally exceeds that of the copper, while in some heavy cores the copper is heavier. The different coatings of gutta percha and of the conductor are usually separated by a thin coating of Chatterton's compound (a mixture of gutta percha, resin, and Stockholm tar), in order to make them adhere firmly together. This practice has recently been departed from by Messrs. Siemens Brothers, who have succeeded by an improved process of manufacture in getting perfect adhesion without the use of the compound. The core is served with a thick coating of wet jute, yarn, or hemp (*h*), forming a soft bed for the sheath, which consists of soft iron, or of homogeneous iron, wires of the best quality. The sheathing wires are usually covered with one or two servings of tarred canvas tape (*t*), or of tarred hemp, laid on alternately with coatings of a mixture of asphaltum and tar. The weight of the iron sheath varies greatly according to the depth of the water, the nature of the sea bottom, the prevalence of currents, and so on. Fig. 2 shows the intermediate type again sheathed with a heavy armor to resist wear in the shallow water near shore. In many cases a still heavier type is used for the first mile or two from shore, and several intermediate types are often introduced, tapering gradually to the thin deep-water type. Captain S. Trot and Mr. F. A. Hamilton have proposed [1] to abandon the iron sheath and substitute a strong double serving of hemp, laid on in such a way as to prevent twisting when the cable is under tension. This suggestion, which is a revival with some modifications of an old idea, is, however, still in the experimental stage.

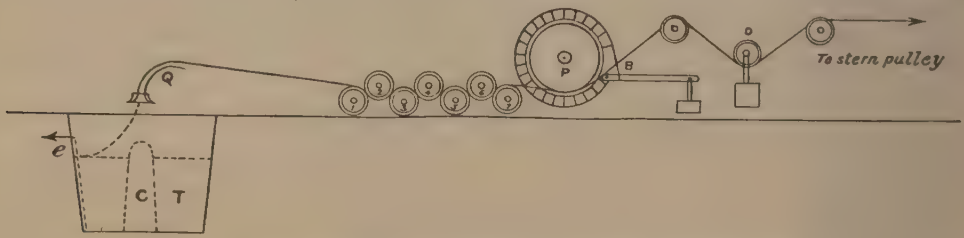

Fig. 6.—Diagram of cable tank and paying out apparatus of submarine cable.

We will now describe very briefly a few of the most important processes in the manufacture and submergence of submarine cables.

Their manufacture. In manufacturing a cable (Fig. 5) the copper strand is passed through a vessel A containing melted Chatterton's compound, then through the cylinder C, in which a quantity of gutta percha, purified by repeated washing in hot water, by mastication, and by filtering through wire-gauze filters, is kept warm by a steam-jacket. As the wire is pulled through, a coating of gutta percha, the thickness of which is regulated by the die D, is pressed out of the cylinder by applying the requisite pressure to the piston P. The newly coated wire is passed through a long trough T, containing cold water, until it is sufficiently cold to allow it to be safely wound on a bobbin B′. This operation completed, the wire is wound from the bobbin B′ on to another, and at the same time carefully examined for air-holes or other flaws, all of which are eliminated. The coated wire is treated in the same way as the copper strand,—the die D, or another of the same size, being placed at the back of the cylinder and a larger one substituted at the front. A second coating is then laid on, and after it passes through a similar process of examination a third coating is applied, and so on until the requisite number is completed. The finished core changes rapidly in its electric qualities at first, and is generally kept for a stated interval of time before being subjected to the specified tests. It is then placed in a tank of water and kept at a certain fixed temperature, usually 75° Fahr., until it assumes approximately a constant electrical state. Its conductor and dielectric resistance and its electrostatic capacity are then measured. These tests are generally repeated at another temperature, say 50° Fahr., for the purpose of obtaining at the same time greater certainty of the soundness of the core and the rate of variation of the conductor and dielectric resistances with temperature. Should these tests prove satisfactory the core is served with jute yarn, coiled in water-tight tanks, and surrounded with salt water. The insulation is again tested, and if no fault is discovered the served core is passed through the sheathing machine, and the iron sheath and the outer covering are laid on. As the cable is sheathed, it is stored in large water-tight tanks and kept at a nearly uniform temperature by means of water.

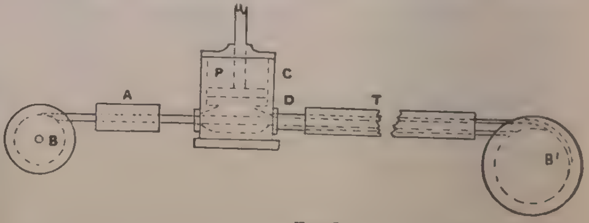

Fig. 5.

Submersion. The cable is now transferred to a cable ship, provided with water-tight tanks similar to those used in the factory for storing it. The tanks are nearly cylindrical in form and have a truncated cone fixed in the centre, as shown at C, Fig. 6. The cable is carefully coiled into the tanks in horizontal flakes, each of which is begun at the outside of the tank and coiled towards the centre. The different coils are prevented from adhering by a coating of whitewash, and the end of each nautical mile is carefully marked for future reference. After the cable has been again subjected to the proper electrical tests and found to be in perfect condition, the ship is taken to the place where the shore end is to be landed. A sufficient length of cable to reach the shore or the cable-house is paid overboard and coiled on a raft or rafts, or on the deck of a steam-launch, in order to be connected with the shore. The end is taken into the testing room in the cable-house and the conductor connected with the testing instruments, and, should the electrical tests continue satisfactory, the ship is put on the proper course and steams slowly ahead, paying out the cable over her stern. The cable must not be overstrained in the process of submersion, and must be paid out at the proper rate to give the requisite slack. This involves the introduction of machinery for measuring and controlling the speed at which it leaves the ship and for measuring the pull on the cable. The essential parts of this apparatus are shown in Fig. 6. The lower end *e* of the cable in the tank T is taken to the testing room, so that continuous tests for electrical condition can be made. The upper end is passed over a guiding quadrant Q to a set of wheels or fixed quadrants 1, 2, 3 ... then to the paying-out drum P, from it to the dynamometer D, and finally to the stern pulley, over which it passes into the sea. The wheels 1, 2, 3, ... are so arranged that 2, 4, 6, ... can be raised or lowered so as to give the cable less or more bend as it passes between them, while 1, 3, 5, ... are furnished with brakes. The whole system provides the means of giving sufficient back-pull to the cable to make it grip the drum P, round which it passes several times to prevent slipping. On the same shaft with P is fixed a brake-wheel furnished with a powerful brake B, by the proper manipulation of which the speed of paying out is regulated, the pull on the cable being at the same time observed by means of D. The shaft of P can be readily put in gear with a powerful engine for the purpose of hauling back the cable should it be found necessary to do so. The length paid out and the rate of paying out are obtained approximately from the number of turns made by the drum P and its rate of turning. This is checked by the mile marks, the known position of the joints, etc., as they pass. The speed of the ship can be roughly estimated from the speed of the engines; it is more accurately obtained by one or other of the various forms of log, or it may be measured by paying out continuously a steel wire over a measuring wheel. The average speed is obtained very accurately from solar and stellar observations for the position of the ship. The difference between the speed of the ship and the rate of paying out gives the amount of slack. The amount of slack varies in different cases between three and ten per cent., but some is always allowed, so that the cable may easily adapt itself to inequalities of the bottom and may be more readily lifted for repairs. But the mere paying out of sufficient slack is not a guarantee that the cable will always lie closely along the bottom or be free from spans. Whilst it is being paid out the portion between the surface of the water and the bottom of the sea lies along a straight line, the component of the weight at right angles to its length being supported by the frictional resistance to sinking in the water. If, then, the speed of the ship be v, the rate of paying out u, the angle of immersion i, the depth of the water h, the weight per unit length of the cable w, the pull on the cable at the surface P, and A, B constants, we have:

---

[1] *Journ. Soc. Telegr. Eng.*, vol. xii. p. 495.

$$\mathrm{P}=h\left\{w-\frac{\mathrm{A}}{\sin i}f(u-v\cos i)\right\}\ \ldots\ldots\ldots\ (a)$$

and $$w\cos i=\mathrm{B}f(v\sin i)\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(\beta),$$

where f stands for "function." The factors $\mathrm{A}f(u-v\cos i)$ and $\mathrm{B}f(v\sin i)$ give the frictional resistance to sinking, per unit length of the cable, in the direction of the length and transverse to the length respectively:[1] It is evident from equation (β) that the angle of immersion depends solely on the speed of the ship; hence in laying a cable on an irregular bottom it is of great importance that the speed should be sufficiently low. This may be illustrated very simply as follows: suppose $a\,a$ (Fig. 7) to be the surface of the sea, $b\,c$ the bottom, and $c\,c$ the straight line made by the cable; then, if a hill H, which is at any part steeper than the inclination of the cable, is passed over, the cable touches it at some point t before it touches the part immediately below t, and if the friction between the cable and the ground is sufficient the cable will either break or be left in a long span ready to break at some future time. It is important to observe that the risk is in no way obviated by the increasing slack paid out, except in so far as the amount of sliding which the strength of the cable is able to produce at the points of contact with the ground may be thereby increased. The speed of the ship must therefore be so regulated that the angle of immersion is as great as the inclination of the steepest slope passed over. Under ordinary circumstances the angle of immersion i varies between six and nine degrees.[2]

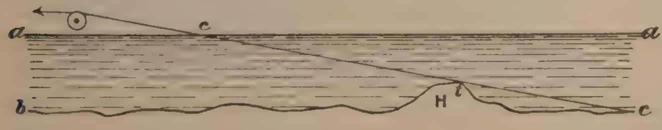

FIG. 7.

Qualities of a Telegraph Line.—The efficiency of the telegraph depends on three qualities of the main line—(1) its conducting quality, (2) its insulation, and (3) its electrostatic capacity.

Conducting quality.

1. The conducting quality of a wire or other elongated portion of matter is measured by the quantity of electricity which it allows to flow through it when a stated "electromotive force," or "difference of electric potentials," is maintained between its two ends. It may be most naturally, and is in point of fact generally, expressed in terms of resistance to transmission, regarded as a quality inverse to that of conducting power, and expressed numerically by the reciprocal of the measure of the conducting power. An independent explanation and definition of the electrical resistance of a conductor may be given as follows: the electrical resistance of a conductor is measured by the amount of electromotive force, or difference of potentials, which must be maintained between its ends to produce a stated strength of electric current through it.

Insulation.

2. The true measure of the insulation of a body is the resistance to conduction offered by its supports. The reciprocal of this, or the conducting power of the supports, measures the defectiveness of the insulation. Since no substance yet known is absolutely a non-conductor of electricity, perfect insulation is impossible. If, however, the supports on which a telegraph wire rests present, on each part and on the whole, so great a resistance to electric conduction as to allow only a small portion of the electricity sent in, in the actual working, at one end to escape by lateral conduction, instead of passing through the line and producing effect at the other end, the insulation is as good as need be for the mode of working adopted. With the good insulation attained in a submarine line, round every part of which the gutta percha is free from flaws, no telegraphic operation completed within a second of time can be sensibly influenced by lateral conduction. A charge communicated to a wire thus insulated under water, at the temperature of the sea-bottom, is so well held that, after thirty minutes, not so much as half of it is found to have escaped. From this, according to the familiar "compound interest" problem, it appears that the loss must be at the rate of less than five per cent. per two minutes.

Electro-static capacity.

3. In 1849 Werner Siemens proved that "when a current is sent through a submerged cable a quantity of electricity is retained in charge along the whole surface, being distributed in proportion to the tension of each point,"—that is to say, to the difference of potentials between the conductor at any point and the earth beside it. In 1854 Faraday showed the effect of this "electrostatic charge" on signals sent through great lengths of submerged wire, bringing to light many remarkable phenomena and pointing out the "inductive" embarrassment to be expected in working long submarine telegraphs. In letters[3] to Professor Stokes in November and December of the same year, Prof. W. Thomson gave the mathematical theory of these phenomena, with formulæ and diagrams of curves, containing the elements of synthetical investigation for every possible case of practical operations. Some of the results of this theory are given at the end of the present article. The conductor of a submarine cable has a very large electrostatic capacity in comparison with that of a land telegraph wire in consequence of the induction, as of a Leyden phial, which takes place across its gutta percha coat, between it and its moist outer surface, which may be regarded as perfectly connected with the earth, that is to say, at the same potential as the earth. The mathematical expressions for the absolute electrostatic capacity C, per unit of length, in the two cases are as follows:

Submarine line.

Let D = diameter of the inner conductor, supposed to be that of a circular cross section, or of a circle inappreciably less than one circumscribed about the strand which constitutes a modern submarine conductor; D′ = outer diameter of the insulating coat; I = specific inductive capacity of the gutta percha or other substance constituting the insulating coat. Then

$$\mathrm{C}=\frac{\mathrm{I}}{2\log_e \mathrm{D}'/\mathrm{D}}.$$

Air line.

In the case of a single wire of circular section, diameter D, undisturbed by the presence of others, and supported at a constant height h above the earth by poles so far apart as not to influence its capacity sensibly—

$$\mathrm{C}=\frac{1}{2\log_e 4h/\mathrm{D}}.$$

---

[3] Published in *Proc. Roy. Soc.* for 1855.

Example 1. In a submarine cable in which $D' = 1$ centimètre; $D = 0.4$ centimètre; and $I = 3.2$:

$$C = \frac{I}{2\log_e D'/D} = \frac{3.2 \times .4343}{2 \times .3979} = 1.75.$$

Example 2. In a land line in which $D = 0.6$ centimètre and $h = 600$ centimètres—

$$C = \frac{1}{2\log_e 4h/D} = \frac{.4343}{7.204} = \frac{1}{16.6}.$$

The capacity, therefore, is in this case less than one-twenty-ninth of that of the submarine cable of example 1 for the same length.

Telegraph Testing.

Standards of measurement.

Standards of Measurement.—A brief consideration of the standards according to which the electrical qualities referred to in the last section are measured, and the measurements to be described in this section are made, will render the statements of those qualities and quantities more definite. A complete and universally comparable system of standards for physical measurements can be obtained by adopting arbitrarily as fundamental units those of length, mass, and time, and expressing in terms of these in a properly defined manner the units of all the other quantities. The units now adopted all over the world for electrical measurements take the centimètre as the unit of length, the gramme as the unit of mass, and the mean solar second as the unit of time. There are two systems in use, the electrostatic and the electromagnetic. In the former the mutual forces exerted by two bodies, each charged with static electricity, are taken as the starting-point, and in the latter the mutual forces exerted between a current of electricity and a magnet. The units according to these two systems are definitely related; but as we deal in the present article with the electromagnetic system we give the following brief account of it only.

Units.

The *dyne* or *unit force* is that force which, acting on a gramme of matter, free to move, imparts to it a velocity of 1 centimètre per second. *Unit quantity of magnetism* or *unit magnetic pole* is that quantity of magnetism which, when placed at a distance of 1 centimètre from an equal and similar quantity of magnetism or a magnetic pole, repels it with unit force. *Unit magnetic field* is a field which, when a unit quantity of magnetism or a unit magnetic pole is placed in it, is acted on by unit force. *Unit current* is a current which, when made to flow round a circle of unit radius, produces a magnetic field of 2π units' intensity at the centre of the circle, or acts on a unit quantity of magnetism placed at the centre of the circle with 2π units of force. *Unit quantity of electricity* is the quantity conveyed by the unit current in one second. *Unit difference of potential* is the difference of potential between the ends of a conductor of unit length when it is placed with its length at right angles to the direction of force in a unit magnetic field and kept moving with a velocity of 1 centimètre per second in the direction at right angles to its own length and to the direction of the magnetic force. *Unit electromotive force* is produced in a closed circuit if any unit of its length is held in the manner, and moved in the direction and with the velocity, described in the last section. *Unit resistance* is the resistance which, when acted on by unit electromotive force, transmits unit current. *Unit capacity* is the capacity of a body which requires unit quantity of electricity to raise its potential by unity. The units above specified are generally referred to as the absolute C.G.S. electromagnetic units of the different quantities. In practice their magnitudes were found inconvenient, and certain multiples and submultiples of them have been adopted as the practical units of measurement: thus the *ohm* is equal to 10^9 C.G.S. units of resistance; the *volt* is equal to 10^8 C.G.S. units of electromotive force; the *ampere* is equal to 10^{-1} C.G.S. units of current; the *coulomb* is equal to 10^{-1} C.G.S. units of quantity; the *farad* is the capacity which is charged to a volt by a coulomb, and is equal to 10^{-9} C.G.S. units of capacity; the *microfarad* is the millionth part of the farad, and is equal to 10^{-15} C.G.S. units of capacity.

We are here chiefly concerned with the units of electromotive force, resistance, and capacity. No universally recognized standard of electromotive force has yet been established, but the want has been to a great extent supplied by the potential galvanometers, electrostatic voltmeters, standard cells, and other instruments devised by Sir W. Thomson and others. The work of Lord Rayleigh, Dr. Fleming, and other experimenters on the Clark and Daniell standard cells has shown conclusively that an electromotive force can be reproduced with certainty within one-tenth per cent. of accuracy by means of either of these cells. Specimens of the standard unit of resistance, or ohm, made of an alloy of platinum and silver, or of platinum and iridium, have been constructed, and can be relied on, if properly taken care of, to remain very nearly accurate from year to year. Similar specimens of the standard unit of capacity or microfarad which remain very nearly constant have been successfully produced. For a fuller treatment of this subject and of the methods of determining the different units, see ELECTRICITY, vol. viii. p. 38 *sq.*[1]

Telegraph line testing consists mostly of comparisons of the resistance of the conductor and the insulator with sets of standard resistances, and of comparisons of the inductive capacity of the line or cable with standard condensers of known capacity. When, as is sometimes the case, the strength of the current flowing through the line or through a particular instrument is to be determined, it is measured by an electrodynamometer, or by a current galvanometer, properly constructed for indicating currents in absolute measure. In the absence of such an instrument it may be obtained accurately by the use of a standard galvanometer in a known or determined magnetic field, or, taking advantage of Faraday's discovery of the electro-chemical equivalents, by measuring the amount of silver or of copper deposited by the current when it is made to pass through an electrolytic cell; or the electromotive force per unit resistance of the circuit may be determined by the use of standard resistances and a standard cell. Space does not allow us to do more than simply refer to these methods, the first two at least of which involve accurate and somewhat difficult experimental work.[2]

Measurement of wire resistance; by Wheatstone's bridge.

Measurement of Wire Resistance.—(1) By *Wheatstone's bridge.*[3] Let l (Fig. 8) be the line with its distant end connected with the earth, a and b known resistances, x a resistance which can be varied, G a galvanometer, K a single lever key, K_1 a reversing key, and B a battery. Put the zinc pole of the battery to the line and adjust the resistance x until the galvanometer G shows no deflection when K_1 is depressed. We then have, assuming no electromotive force in the line, $l = ax_1/b$. Next put the copper pole to the line and repeat the test, and suppose in this case $l = ax_2/b$; if these two values of l nearly

Gray, *Absolute Measurements in Electricity and Magnetism*, London, 1884.

[2] See A. Gray, *Absolute Measurements in Electricity and Magnetism*, pp. 27, 74; also T. Gray, *Phil. Mag.*, November, 1886. The following quotation from the art. TELEGRAPH in the 8th ed. of the *Ency. Brit.* shows how comparatively recent is the introduction of anything like absolute measurement in telegraph testing: "The ordinary test for insulation consists in applying a galvanic battery, with one pole to earth and the other through a galvanometer coil, to the line of telegraph of which the remote end is kept insulated. If the insulation of the whole line were perfect, the galvanometer needle would stand at zero; but, when looked for with a battery of suitable power and a galvanometer of suitable sensibility, indications of a current are always found, unless it is a very short length of very perfectly insulated line that is tested. The absolute measure of the strength of this current divided by the absolute measure of the electromotive force of the battery gives an absolute measure for the insulation of the cable. No telegraphic testing ought in future to be accepted in any department of telegraphic business which has not this definite character, although it is only within the last year that convenient instruments for working in absolute measure have been introduced at all, and the whole system of absolute measurement is still almost unknown to practical electricians." It was put in practice systematically for the first time in 1859, in experiments by Prof. F. Jenkin.

[3] For this theory, see ELECTRICITY, vol. viii. p. 41-3.

agree the true value may be taken as $2ax_1x_2/b(x_1+x_2)$. The effect of an electromotive force in the line itself is nearly eliminated by reversing the battery.

By direct deflection.

(2) Let the battery B (Fig. 9) be connected through the keys K_1 and K and the galvanometer G with the line *l*, which has its distant end to the earth as before; shunt the galvanometer by a shunt *s* until a convenient deflection is obtained, and then take as quickly as possible a series of readings with zinc and copper alternately to the line. Next substitute for *l* a set of resistance coils and vary the resistance until the same series of readings is obtained. The resistance introduced for the reproduction of each reading indicates the apparent resistance of the line when that reading was taken. The readings will generally differ because of the existence of a variable electromotive force in the line. If, however, the difference is not very great, the harmonic mean of the arithmetic mean of the resistances, when zinc and copper were respectively to the line, will give nearly the true resistance. Since the deflections are reproduced by substituting resistances for the line, the galvanometer zero may be off the scale to one side, and hence the total deflection, and therefore the sensibility, may be made very considerable. In this case the reversing key K is required for keeping the deflection in the same direction. With a perfectly insulated battery this can be accomplished by putting the galvanometer between the battery and the key K; but the arrangement shown is safer. The most suitable galvanometer for these tests is a dead-beat mirror galvanometer with a long enough suspension to prevent error from the viscosity of the fibre. Such an instrument is much to be preferred to the astatic form, especially when variable earth-currents are present.

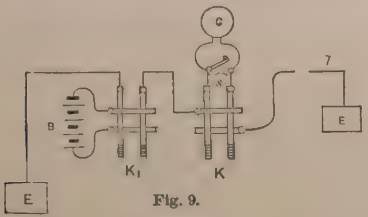

Fig. 9.

By differential galvanometer.

(3) A highly sensitive modification of method (2) is obtained by the use of a differential galvanometer, one coil of which is joined in circuit with the standard resistances and the other coil with the line. The resistances are then adjusted to balance, or to give no permanent deflection when the battery curcuit is closed. Several balances with positive and negative currents must be taken and the results combined as indicated above.

By electrometer.

(4) When an electrometer is employed for testing insulation, as described below, it may be used for the wire resistance also either by substituting it for the galvanometer in Wheatstone's bridge method (Fig. 8, G) or by that shown in Fig. 10. One pole of the battery B is joined to the line through the reversing key K and the resistance R, the other pole being to the earth. The electrometer *El.* is then applied to the two ends of R and to the end of *l* and the earth alternately and the relative deflection noted. The deflections should be as nearly as possible equal; that is, R should be as nearly as possible equal to *l*. The form of reversing key shown at K_1 is convenient for this test, as it allows the comparison to be made quickly; and as the readings can be always taken to the same side of zero, the whole length of the scale is available for each deflection. The key consists of two ordinary front and back stop single lever keys fixed together by an insulating piece *i* at such a distance apart that the contact stops *a*, *b* and *c*, *d* are at the corners of a square. Suppose one pole of the battery put to the line and the resistance R adjusted until no change of deflection is obtained by depressing K_1: then R is equal to *l* if there is no earth disturbance. Then put the other pole of the battery to the line: turn the levers of K through 90° round the pivot *p*; and repeat the adjustment of R for a second determination of *l*. Repeat these measurements several times and combine the results in the manner described in method (2). If R is not made equal to *l*, the resistances are in the ratio of the corresponding deflections.

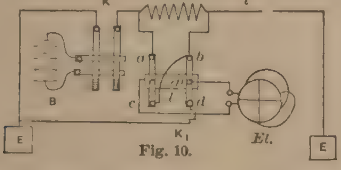

Fig. 10.

Measurement of insulator resistance; direct deflection method.

Measurement of Insulator Resistance.—(1) In the direct deflection method the connections are the same as those shown in Fig. 9, except that the distant end of the line is insulated. Very great care must be taken that the galvanometer and all the connections between it and the end of the line are so well insulated that no sensible part of the observed deflection is due to leakage through them. In making the test, first earth the line for five minutes; then, with the galvanometer short-circuited, apply the zinc pole of the battery to the line; at the end of from thirty seconds to a minute, depending on the length and capacity of the line, remove the short-circuit plug; and record the deflection at the end of every ten or fifteen seconds during the whole time (usually from ten to twenty minutes) the test is continued. Again earth the line for an interval equal to that during which the battery was applied; then apply the copper pole of the battery and repeat the readings as before. Using the deflections as ordinates and the corresponding times as abscissæ, construct a smooth curve for both the zinc and the copper test. The galvanometer constant divided by the mean ordinate of these curves at any time gives the insulation at that time. To determine the galvanometer constant, substitute a high resistance R, say one megohm, for the line, and shunt the galvanometer with a shunt *s*. If the deflection under these circumstances is *d* and G is the galvanometer resistance, the constant is

$$C = Rd\frac{G+s}{s}.$$

Electrometer method.

(2) The electrometer method is only applicable to lines of considerable inductive capacity, but is particularly well suited for cable testing. The battery B (Fig. 11) is connected through a reversing key K_1 to the ends of the resistance slide *ab*, one end of which is put to earth. The slide generally consists either of 10 or 100 equal resistances, amounting in the aggregate to from 10,000 to 100,000 ohms. The cable can be connected by means of the reversing key K to either pair of quadrants of the electrometer *El.*, the slider *s* being at the same time put to the other pair. To determine the constant of the electrometer, connect the earth wire *w* with the cable terminal and the slider with contact 1, and observe the deflection; this should be the same for both directions of the current through the slide; its value multiplied by 10, when the slide is made up of ten coils, gives the value in scale divisions of the full difference of potential between the ends of the slide. This number added to the zero reading of the electrometer is called the *inferred zero*. To find the insulation of the cable, remove the wire *w*, put in the short circuit plug *p*, move the slider to contact 10, and, the distant end of the cable being insulated, apply by means of K_1 the zinc pole of the battery to the cable and the copper pole to the earth. Allow sufficient time for the cable to charge—say one minute for a cable of 2000 knots—then remove the short-circuit plug and take readings every fifteen or thirty seconds. The difference of these readings from zero gives the fall of potential of the cable due to discharge through the insulating coat. Next earth the cable at both ends for a time equal to the duration of the last test, and after reversing K put the copper pole of the battery to the cable and the zinc pole to the earth and take another series of readings. Subtract these readings from the inferred zero, and, using the differences as ordinates and the corresponding times as abscissæ, draw two curves. To find the insulation of the cable at any

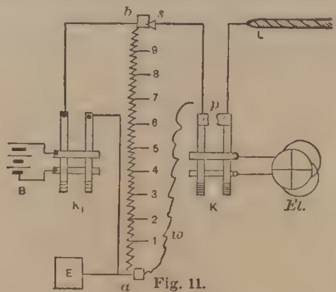

Fig. 11.

interval t after the battery was applied, draw a tangent to the curve at the point corresponding to that time and produce it to cut the axis of the ordinates. Let D_1 be the ordinate to the point of intersection, and D the ordinate at the time t; then, if C be the capacity of the cable in microfarads and I its insulation in megohms,

$$I = \frac{tD}{C(D_1 - D)}.$$

If the difference between the reading and the inferred zero at the times t and t_1 be D and D_1, the insulation is given by the equation

$$I = \frac{.4343(t_1 - t)}{C \log D/D_1},$$

when $t_1 - t$ is reckoned in seconds. This latter is the formula commonly used; it gives the insulation at some time in the interval between the two observations; the exact time depends on the rate of "absorption" of the cable.

The advantages of the electrometer method of testing cables are the comparative steadiness of the needle during earth-current disturbances, its high sensibility for the detection of small intermittent faults, and the fact that simultaneous tests can be taken from both ends of the cable. In order to test from both ends simultaneously one or other of the following methods may be adopted. Call the ends of the cable A and B, and suppose the operator at A is to begin the test. The operator at B joins the copper pole to the earth and the zinc pole to the line, and leaves the slider of his slide resistance at the earth end of the slide. Then, at a time previously arranged, he watches until he sees the electrometer begin to indicate a charge in the cable, and moves the slider along the slide so as to keep the electrometer near zero. As soon as the electrometer ceases to indicate increase of charge he ceases to move the slider and begins to record the deflections at regular intervals, the first reading being taken as zero. The other method is to leave the slider permanently to earth and keep the electrometer so insensitive that the deflection is always within the limits of the scale. Observe the time at which the electrometer begins to be deflected, and from that time onward take readings every thirty seconds during the time of the test. The mean of the readings taken at both ends, reduced to the same sensibility, should be used for calculating the insulation. This method not only eliminates the effects of earth-current disturbance but also throws light on the nature and distribution of such disturbances.

Fall of potential method by galvanometer.

When an electrometer is not available and the line is too much disturbed for good tests to be obtained by the galvanometer method, the following procedure may be adopted. Join the battery and the galvanometer in series with the cable as for the direct deflection test. Short-circuit the galvanometer and charge the cable for one minute. Insulate the cable for fifteen seconds; then break the short circuit of the galvanometer; again apply the battery, and take the deflection produced by the charge. Keep the battery on the cable for fifteen seconds, and during that time take if possible the direct deflection reading two or three times. Again insulate for fifteen seconds and repeat the above readings; and continue the same cycle of operations for the whole time of the test. After earthing the cable for the proper interval repeat the above test with the other pole of the battery to the cable. To reduce the charge readings to absolute measure, find the deflection of the galvanometer needle due to the charge of a condenser of n microfarads capacity by the testing battery; let d be this deflection. Then the deflection that would be obtained by charging the whole cable would be Cd/n, and, if D be any one of the deflections during the test, Dn/Cd is the fraction of the whole charge which has been lost in the fifteen seconds immediately preceding this charge; thus

$$I = \frac{.4343 \times 15}{C \log \dfrac{C^2d^2}{C^2d^2 - n^2D}}.$$

The method just described takes advantage in a somewhat imperfect manner of both the direct deflection and the electrometer test; but the galvanometer should have such a long period that the whole of the charge can take place before the needle is sensibly moved from its zero position, and that the vibration of the needle must not be damped to any great extent,—a condition which renders the instrument unsuitable for direct deflection testing.

The points with regard to the cable which should be particularly attended to when testing for insulation are—the continuity of the insulation all through the test, that is, there should be no sign of a breakdown for ever so short a time; the rate of polarization with positive and negative current is always the same in a perfect cable, but is seldom so when a fault exists; the absolute insulation with both currents should also be the same if the cable is perfect, but is never so for any length of time when a fault exists. If the insulations show any sign of being defective great care must be taken not to apply a powerful battery to the cable, unless the object is to increase or "break down" the fault. The resistance of a fault is generally diminished by applying the zinc pole of the battery to the cable and increased by applying the copper pole; but if the fault is small it sometimes happens that both currents increase the resistance. Even a very powerful battery may in such a case fail to increase the fault.

Thomson's capacity test.

Capacity Tests.—The arrangement of the connections for Thomson's capacity test are shown in Fig. 12. A well-insulated battery B is connected through a reversing key K_1 to the slide resistance *ab*, and by means of a key K *a* can be put to a standard condenser C and *b* to the cable, or the condenser and the cable can be connected together and then both put to earth through the galvanometer G by closing the key K_2. Any point in the resistance *ab* can be put to earth by means of the slider *s*. Suppose the middle point put to the earth, then C and L will be charged to equal potentials but of opposite sign. If the connections to the slide are broken and C is joined to L, the resulting charge will be zero when the capacity C is equal to the capacity L, and when K_2 is closed no current will flow through G. Similarly, if *as* is to *sb* as L is to C the resulting charge is zero. Hence when, after joining C to L, no deflection is shown on G when K_2 is closed—

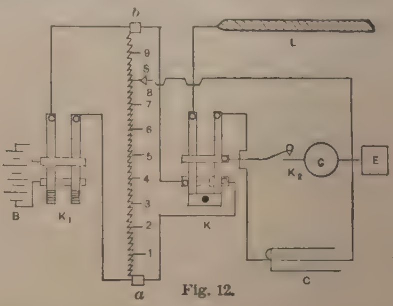

Fig. 12.

$$L = C\frac{as}{sb}.$$

Gott's test.

A modification of this test has been suggested by Mr. John Gott. The condenser C is joined in series with the cable and one end of the slide is put to earth. The galvanometer G is joined from the end of the cable to the slider *s*, and the position of the latter, which gives no deflection, is found by successive trials, the cable being discharged and recharged between the trials. A small condenser in the galvanometer circuit is an advantage, as it allows several adjustments to be made without discharging the cable. The most suitable instrument, however, is an electrometer, as it allows the adjustment to be made at once.

De Sauty's test.

The capacities of condensers may be compared by charging or discharging them through a galvanometer and comparing the deflections, or, as in De Sauty's method, by substituting them for two sides of a Wheatstone's bridge and finding the ratio of the resistances in the other two sides; then, with the galvanometer circuit closed, the battery circuit can be closed without producing any deflection. The galvanometer circuit must join the condensers at the same points as the bridge resistances. These methods are quite unsuited for telegraph-line testing because of the resistance and the inductive retardation of the line.

Tests of submerged cable.

Tests of a Submerged Cable.—During the submergence of a cable it is necessary to provide the means of knowing at every instant whether it continues in perfect electrical condition, so that should any fault develop it can be at once detected and further paying out stopped until it is removed. It is also of great importance that the ship and shore should be in telegraphic communication with each other. The arrangements made for these purposes by different electricians vary considerably; but the general principle will be gathered from Fig. 13, which includes all that is absolutely necessary for the purpose. The principal testing station is always on board the ship, and from it all the testing operations both on board and on shore are regulated. Referring first to the arrangements on board, B is the testing battery, K the testing key, and G the testing galvanometer; B_1 is the signalling or "speaking" battery, K_1 the key, and G_1 the galvanometer; R is a resistance box and E the earth-plate —the ship's side in this case. The battery B is connected through the key K, the resistance R, and the galvanometer G to the cable, as for direct deflection testing. The shore end of the cable is at the same time connected to one set of plates of a highly insulated condenser C_1 and (although this may be omitted) to one pair of quadrants of an electrometer *El.* The other pair of plates of the condenser are put to earth through the signalling key K_1. It is convenient also to have a second condenser C, on shore, the capacity of which can be readily varied, so arranged that its capacity can be added to that of C_1 by depressing the key K, and again discharged through a galvanometer G by releasing the key. The operations are then conducted as follows: The insulation is measured on board ship, alternately with positive and negative currents of from ten to fifteen minutes' duration, by observing the deflection on the galvanometer G; and the reading at the end of each minute, or oftener, is recorded in a diary. The continuity of the conductor is tested at short intervals—say every five minutes —by the observer on shore depressing the key K and thus adding the capacity of C to the cable. This gives a sudden deflection on the galvanometer G on board, and at the same time shows that the conductor is continuous and that the observer on shore is attending to his duties. When the shore key K is released, the discharge through G is indicated by a throw deflection, the amount of which is recorded in the diary and shows the potential to which the shore end of the cable is kept charged. When the electrometer *El* is used, a continuous test of the potential at the shore end is obtained, and the development of a fault in the cable is at once indicated. It is convenient for this purpose to dispense with the charge in the electrometer jar and needle and connect the needle to the pair of quadrants which are joined to the cable. The deflection is then proportional to the square of the potential and is always to one side of zero, so that the whole range of the scale is available for the deflection. The tests for wire-resistance and capacity are practically the same as those already described. They are in ordinary circumstances of much less importance than the insulation tests. The wire-resistance test is of great value, however, for giving a close estimate of the temperature of the submerged cable, and hence for giving the means of comparing the tests of the submerged cable with those of the cable previous to submersion. In laying short lengths of cable the shore station may be dispensed with and capacity tests relied on for continuity. Communication between ship and shore is carried on by means of the keys K_1, K_1, the galvanometer G_1 and the batteries B_1, B_1. The signalling key on board the ship adds or subtracts the electromotive force of the battery B_1 from the testing battery, and hence varies the potential of the cable. This is shown on shore by the partial charge or discharge of C_1 passing through the galvanometer G_1 and is interpreted in accordance with the single needle alphabet in the ordinary way. In a similar manner the signalling key on shore varies the charge of C_1, and so causes slight variations of the testing-current on board the ship, which are read on the galvanometer G_1 and interpreted in the same way. The testing is usually suspended during the signalling; but if the message is long an insulation reading is taken every few minutes according to pre-arrangement.

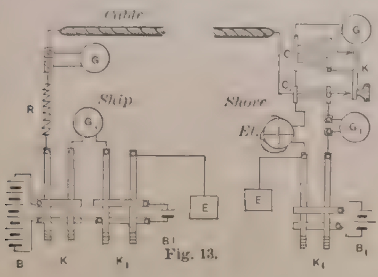

Fig. 13.

Marine galvanometer.

The galvanometers used at sea require to be constructed so that the rolling of the ship does not deflect the needle, either on account of its inertia and the action of gravity, or of the relative changes in the position of the ship's magnetism. The best form of marine galvanometer consists of two short bobbins of fine silk-covered wire placed end to end, about an eighth of an inch apart, and having their axes in the same line, with a very light mirror, carrying cemented to its back one or more small magnets suspended between the two bobbins in such a way that the centre of the mirror is in their common axis. The mirror and magnet system weighs from one-half to one grain. It is suspended as shown in Fig. 14 by a single silk fibre *f*, which passes through the centre of inertia of the mirror and needle system *m* and is fixed at one end directly to the frame F and at the other end to a light spring *s*. The frame F is made thin enough to slide into the opening between the two bobbins, so that the mirror can be easily taken out for adjustment when necessary. So long as the suspending fibre passes through the centre of inertia of *m* it is clear that no motion of translation of F can produce rotation of the mirror. When the instrument requires to be highly sensitive, as for testing purposes, it is shielded from the action of the ship's and the earth's magnetism by enclosing it in a massive iron case. For signalling purposes the controlling magnet is arranged to produce at the needle a field so strong that the effect of variations of external magnetism is inappreciable.

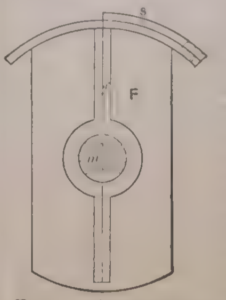

FIG. 14.—Marine galvanometer.

Testing for Faults.—Numerous methods have been proposed for the localization of faults in telegraph lines, some of a complex character and adapted to the cases of faults of a kind which fortunately seldom, if ever, occur. We give here a brief outline of the tests for the cases of most common occurrence.

Complete rupture with conductor insulated.

For the determination of the position of a complete rupture with the conductor insulated both the insulation and the capacity tests are theoretically applicable. The insulation of a line of uniform type and material is inversely as its length; hence if a piece is broken off the insulation is increased. If I be the total insulation before rupture, I_1 the insulation of one section after rupture, and *l* the total length of the line, the length of the section is Il/I_1. Unfortunately it is difficult to obtain the necessary accuracy in insulation testing on account of the great influence of earth-currents on the result; but apart from this there is always some uncertainty, especially in cables, as to the insulation at the break. For cables a fairly reliable test can be obtained from the capacity even when the insulation at the fault is somewhat imperfect, if it be sufficient to hold the greater part of the charge for a few seconds, since the amount of loss in any short interval can be estimated by a separate test. The capacity of a uniform cable is inversely as its length; hence, if C be the total capacity of the perfect cable and C_1 the capacity of one section, the length of that section is lC_1/C. When—as is almost always the case—the cable is not quite uniform in electrical quality and in temperature, a table or a curve showing the wire resistance, the insulation and the capacity up to any point from either end should be kept for reference.

Complete fracture with end partially earthed.

It is not at all uncommon in cables for one side of a fracture to be partially insulated through the conductor not breaking exactly at the same point as the insulator. In this case, however, the other end will be in most cases almost perfectly earthed and the position of the fault can be very nearly determined by the wire-resistance test. When both ends are partially insulated it is very difficult to obtain a near approach to the position of the fault because of the uncertainty as to which side of the break offers the greatest resistance. A first approximation is obtained by finding the wire resistance from both ends and subtracting the total wire resistance of the cable from the sum of these. This gives the sum of the resistances at the fracture, and half of this, if it is not too great, subtracted from the resistance of either section gives an approximation to the resistance of that section up to the break. If, however, the resistance at the fracture is comparable to the total wire resistance of the cable, this method is useless. An approach to the solution of the difficulty can be obtained from capacity tests, the cable being discharged through different resistances at the testing end. But the procedure is very uncertain and difficult, and a full discussion of it would take more space than can be afforded here. The resistance at a fault can sometimes be greatly diminished by repeated application alternately of the positive and negative poles of a powerful battery to the cable, but this should never be resorted to if it can possibly be avoided. The direct deflection method of taking wire resistance is most suitable for these tests. The resistance seems to diminish gradually after the battery is applied until it reaches a minimum value, after which it again increases. This maximum deflection should be taken as indicating most nearly the true wire resistance up to the fracture.

Partial earth without fracture.

When the fault is a partial earth without fracture, and both ends of the cable are available—as in factory testing, or when a second well-insulated cable can be used — the most satisfactory method is the loop test. In this the two sections of the cable form two sides of the Wheatstone's bridge; one pole of the battery is put to the junction of the other two sides and the other pole to earth,— that is, practically to the fault. The ratio of the resistances in the bridge when balance is obtained gives the ratio of the resistances of the two sections of the cable, or the ratio of the resistance of one section to the resistance of the other section plus the resistance of the second cable. The total resistance of the cable being known, it is easy to determine the position of the fault. When the fault has a high resistance it is necessary to make a correction for the want of perfect insulation in the sound part of the cable. When both ends of the cable are not available, measure the potential at the testing end and the resistance between that end and the earth, and simultaneously measure, by means of a slide resistance and zero galvanometer or by means of a quadrant electrometer, the potential at the distant end. Then, if V be the potential at the testing end, v the potential at the distant end, and R the resistance measured, the true resistance of the fault is $R(1-v/V)$. Another simple, although less perfect method, may be mentioned. Measure the resistance between both ends and the earth and subtract from the sum the true wire resistance of the cable; the difference is twice the resistance of the fault. The imperfection of this method, and indeed of any which involves two observations not made simultaneously, lies in the variable character of the resistance of a fault.

III. Modern Telegraphs.

Morse system.

The code of signals introduced by Morse is still employed in the United States and Canada, and the international code in vogue in Europe differs only slightly from it. Currents in one direction only are used, and different combinations of from one to four long and short contacts form the letters, while the numerals are represented by groups of five signals, and punctuation and other special signs by groups of six and sometimes more. The instruments used for land telegraphs on this system are of two types,—"sounders," which indicate by sound, and "recorders," which record the signals.

Morse recorders.

(1) Recorders vary in details of construction, but all have the same object, namely, to record the intervals during which the current is applied to the line. In the earlier forms of instrument the record was made by embossing lines on a ribbon of paper by means of a sharp stile fixed to one end of a lever, which carried at the other end the armature of an electromagnet. This method of recording is still largely employed in America, and certainly has the advantage of simplicity. The form of instrument almost universally used in Europe makes the record in ink, and hence is sometimes called the "ink-writer." This method has the advantage of distinctness, and so is less trying to the eyes of the operators. The action of the instrument will be understood from the annexed sketch (Fig. 15). Suppose s to be a strip of paper which is being pulled towards the left by means of two rollers, r_1 and r_2, moved by a train of mechanism. Underneath the roller r_1 a small wheel i is kept turning by the same mechanism and has its lower edge in contact with the surface of ink in the ink-well w. When a current is sent through the magnet m, the armature a is attracted and the lever l lifts the ink-wheel i into contact with the paper, against the surface of which it rolls until the current is broken, thus making a mark the length of which depends on the speed of the mechanism and the time the current flows. As the speed of the mechanism is nearly constant, the relative length of the marks depend only on the duration of the current. In this way the letters of the alphabet, or any other understood signs, are indicated by groups of long and short marks, commonly called "dashes" and "dots."

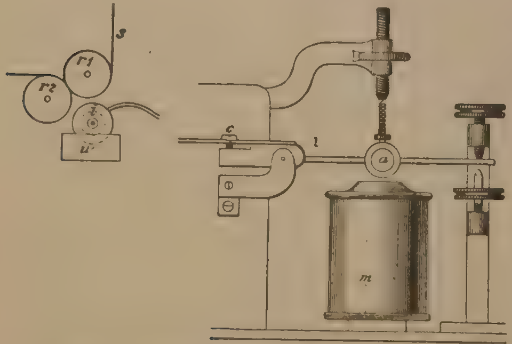

Fig. 15.—Morse ink-writer, one-fourth full size.

Morse sounders.

(2) Operators who use the recording instrument soon learn to read the message by the click of the armature against its stop, and as this is a less fatiguing method of reading, and leaves the hands and eyes free to write, the sound is usually preferred. Thus, when it is not necessary to keep a copy, a much simpler instrument may be employed and the message read by sound. The earliest successful form was Bright's bell sounder, which consisted of two bells of distinct tone or pitch, one of which was sounded when the current was sent in one direction and the other when it was reversed. This instrument was capable of giving very considerable speed, but it was more complicated than that now in use, which consists only of an electromagnet, with its armature lever arranged to stop against an anvil or screw b (Fig. 16) in such a way as to give a distinct and somewhat loud sound. Dots and dashes are distinguished by the interval between the sounds of the instrument in precisely the same way as they are distinguished when reading from the recorder by sound. The form of sounder commonly used in England is shown in Fig. 16; it is one of the simplest possible instruments, is easily adjusted to the current by tightening or slackening the spring s, and is very little liable to get out of order.

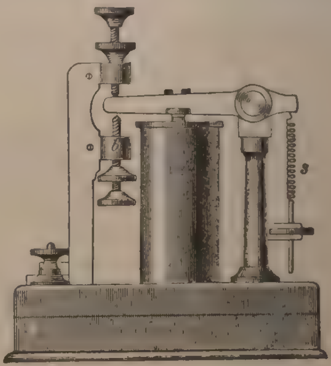

Fig. 16.—Morse sounder, one-fourth full size.

Chemical telegraphs.

Another and in some respects a simpler method of recording is to use a chemically prepared ribbon of paper. Suppose, for instance, the paper ribbon to be soaked in a solution of iodide of potassium and a light contact spring made to press continuously on its surface as it is pulled forward by the mechanism. Then, if a current is sent from the spring to the roller through the paper, a brown mark will be made by the spring due to the liberation of iodine. This was the principle of the chemical telegraph proposed by Edward Davy in 1838 and of that proposed by Bain in 1846. It gives a ready means of recording on the Morse plan at a high rate of speed, and Bain's telegraph was successfully worked for some years in America. Several ingenious applications of his method have been proposed, as, for example, the copying telegraph of Bakewell and of Cros, by means of which a telegram may be transmitted in the sender's own handwriting; the pantelegraph of Caselli; the autographic telegraphs of Meyer, Lenoir, Sawyer, and others; and the autographic typo-telegraph of Bonelli. The principle of action of these instruments is this: Suppose two metallic cylinders, one at the sending and the other at the receiving station, to be kept revolving synchronously, and suppose the axis of each to be threaded with a fine screw so that as it revolves rapidly it has a slow side motion. Wrap round the cylinder at the sending station a ribbon of tinfoil, or paper covered with a conducting coating, on which the message is written in varnish or some other insulating substance. Suppose also a ribbon of paper which has been soaked in iodide of potassium to be wrapped round the cylinder at the receiving station. Cause a style, as in the Bain telegraph, to press on each cylinder and set it in motion. It is evident that so long as the style at the sending end presses on the clean foil the style at the receiving end will continue to make a brown mark, but that when it passes over the varnish the mark will be interrupted. In this way, as the two cylinders revolve and move sideways, the series of interruptions made at the receiving end form an exact copy of the varnish marks at the sending end. These instruments are at present but little used.

Automatic telegraphs.

It has been found possible to make the Morse ink-writer so sensitive that it can record signals sent over land lines of several hundred miles in length very much faster than they can be transmitted by hand, and this has led to the adoption of automatic methods of transmission. One was proposed by Bain as early as 1846, but it did not come into use. That now employed is, however, practically a development of his idea. It consists in punching, by means of "a puncher," a series of holes in a strip of paper in such a way that, when the strip is sent through another instrument, called the "transmitter," the holes cause the circuit to be closed at the proper times and for the proper proportionate intervals for the message to be correctly printed by the receiving instrument or recorder. The most successful apparatus of this kind is that devised by Wheatstone; others have been introduced by Siemens and Halske, Garnier, Humaston, Siemens, and Little.

Wheatstone's automatic system.

In Wheatstone's automatic apparatus three levers are placed side by side, each acting on a set of small punches and on mechanism for feeding the paper forward a step after each operation of the levers. The punches are arranged as shown in Fig. 17, and the levers are adjusted so that the left-hand one moves *a*, *b*, *c*, and punches a row of holes across the paper (group 1 in the figure), the middle one moves *b* only and punches a centre hole (2 in the figure), while the right hand one moves *a*, *b*, *d*, *e*, and punches four holes (3 and 4 in the figure). The whole of this operation represents a dot and a dash or the letter "a." The side rows of holes only are used for transmitting the message, the centre row being required for feeding forward the paper in the transmitter. The perforation of the paper when done by hand is usually performed by means of small mallets, but at the central telegraph office in London the keys are only used for opening air-valves, the actual punching being done by pneumatic pressure. In this way several thicknesses of paper can be perforated at the same time, which is a great convenience for press work, since copies of the same message have often to be transmitted to several newspapers at the same time. The mode of using the paper ribbon for the transmission of the message is illustrated in Fig. 18. An ebonite beam E is rocked up and down rapidly by a train of mechanism and moves the cranks A and B by means of two metal pins *p*, *p*. A and B are in metallic contact with each other through the springs *s*, *s*, and they carry two light vertical rods M, M_1, the one as much in front of the other as there is space between two successive holes in the perforated ribbon. To the other ends of A, B rods H, H_1 are loosely hinged, their ends passing loosely through holes in the ends of the bar P, which is fixed to the divided disk D. By means of two collars K, K_1 and the wheel W, the disk D is made to oscillate in unison with the beam E. The cranks C and C_1 are connected with the poles of the sending battery B. The operation is as follows: The paper ribbon R is moved forward by its centre row of holes at the proper speed above the upper ends of the rods M, M_1; should there be no hole in the ribbon it pushes the crank A or B out of contact with the pins *p*, *p* and prevents a current passing to the line. Should, however, a row of holes, like group 1 above, be perforated, the rod M_1 will first be allowed to pass through the paper and copper will be put to the line; at the next half stroke of the beam, M will pass through, and as the disk D reverses the battery zinc will be put to the line. Thus for a dot first a positive and then a negative current are sent to the line, the effect of the positive current continuing during the time required for the paper to travel the space between two holes. Again, suppose groups 3 and 4 to be punched. The first part will be, as before, copper to the line; at the next half stroke of the beam M will not pass through, as there is no hole in the paper; but at the third half stroke it passes through and zinc is put to the line. Thus for a dash the interval between the positive and the negative current is equal to the time the paper takes to travel over twice the space between two successive holes. Hence for sending both a dot and a dash reverse currents of short duration are sent through the line, but the interval between the reversal is three times as great for the dash as for the dot. In the receiving instrument the electromagnet is so constructed that the armature, if pulled into any position by either current, remains in that position, whether the current continues to flow or not, until a reverse current is made to act on the magnet. For the dot the armature is deflected by the first current, the ink-wheel being brought into contact with the paper and after a short interval pulled back by the reverse currrent. In the case of the dash the ink-wheel is brought into contact with the paper by the first current as before and is pulled back by the reverse current after three times the interval. The armature acts on an inking disk on the principle described above, save only that the disk is supplied with ink from a groove in a second wheel, on which it rolls; the grooved wheel is kept turning with one edge in contact with ink in an ink-well. By this method of transmission the battery is always to the line for the same interval of time, and alternately with opposite poles, so that the effect of electrostatic induction is reduced to a minimum. Through the instrumentality of this method as many as 400 words per minute have lately been transmitted by Mr. Preece between London and Newcastle, a distance of 278 miles.

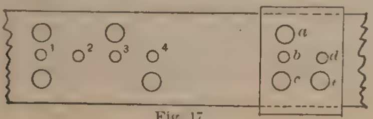

Fig. 17.

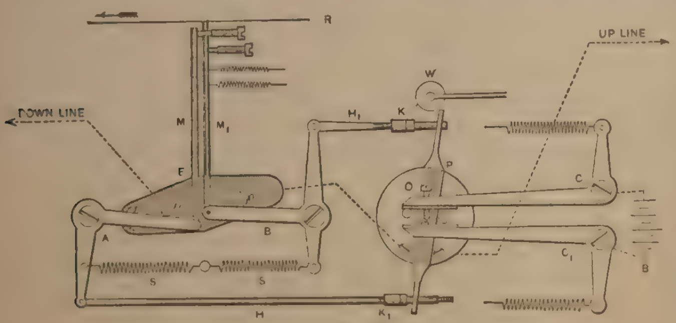

Fig. 18.

Hughes's type-printing telegraph.

The first considerable improvement on the House type-printer, referred to above, was made by D. E. Hughes of Kentucky in 1856. In the Hughes instrument (see Fig. 19) two trains of clockwork mechanism, one at each end of the line, are kept moving synchronously by powerful spring governors. Each instrument is provided with a key-board, resembling that of a small piano, the key levers of which communicate with a circular row, R, of vertical pins. A horizontal arm, A, fixed to a vertical shaft in gear with the mechanism sweeps over these pins at the rate of from one to two turns per second. When a key is depressed, slightly raising one of the pins, the battery is put to the line for a short time at that part of the revolution by means of a sledge, S, carried by the horizontal arm. The current thus sent to the line may be made either to act directly on the printing instrument or to close a local circuit by means of a relay. For simplicity we will suppose direct action. The current then passes through the coils of a powerful electromagnet, M, which relieves the printing mechanism. The electromagnet consists of two coils, each containing a soft iron core of the same length as the coil. These cores rest on the ends of the two arms of a powerful horseshoe permanent magnet, and thus become strongly polarized by induction. A soft iron armature is placed across the free ends of the soft iron cores and is pulled by a strong spring, the tension of which is adjusted so as to be nearly equal to the magnetic attraction. The current is sent in the proper direction to diminish the power of the magnet and allow the spring to preponderate. A very powerful action is thus obtained by means of a very small current, the actual work being done by motive-power in the instrument itself. After the letter is printed the mechanism short-circuits the magnet and replaces the armature automatically. The printing action is as follows: The type-wheel W is carried round continuously by the clockwork, to which it is attached through a friction sleeve which allows it to be stopped, and pushed backward or forward without stopping the mechanism. Another shaft carrying three cams is arranged so as to be locked into gear with the wheelwork when the armature leaves the poles of the magnet. The cams then come into action in rotation; the first moves the adjustment lever, shown to the left of W in the figure, which pushes a wedge-shaped piece into the teeth of the type-wheel and adjusts it exactly to the proper position for printing; the second cam presses the paper against the type; the third moves forward the paper; a fourth cam replaces the armature of the magnet and relieves the cam shaft, leaving the instrument ready to receive another letter. The whole of this operation occupies only a small fraction of a second. By means of the adjustment lever or "corrector" *l* every error in synchronism decidedly less than half the space from letter to letter is perfectly corrected each time an impression is made. Thus, during the time the receiving instrument at one station is in use, its type-wheel is kept in perfect agreement with the sending wheel at the other station; and, if the electric action keeps time, a wrong letter cannot be printed unless the rate of the clockwork is at fault by some such amount as one or two per cent. If the two wheels are allowed to run a long time without the electric maintenance of agreement, they will be found more or less at variance, as the pieces of clockwork, however good, cannot be perfect. All that is necessary to bring them into agreement again is to strike several times the key corresponding to a prearranged adjustment signal—that corresponding to the dot type, for instance. The receiver knows (according to the regulated system of working) that it is adjustment, not message, that is being sent; and he turns his type-wheel by hand till it prints dots. He then signals back "O.K." ("All correct!") and is ready to receive the message. If by any accident his type-wheel gets on a wrong letter in the course of a message, he disturbs the sender (who all the time sees the effect of his sending printed before his own eyes) by sending back a few currents on him; he receives dots by way of acknowledgment, and resets his type-wheel to print correctly. This system of telegraphic printing has a great advantage over the step-by-step system in using continuous instead of intermittent currents, and so avoiding the necessity for the rapidly acting electric escapement, which, however skilfully planned and executed, is always liable to failure when worked too rapidly. In Hughes's instrument almost perfect accuracy and certainty have been attained; and in actual practice it has proved to be decidedly superior to all previous type-printing telegraphs, not only in speed and accuracy, but in less liability to mechanical derangement from wear and tear and from accident. It involves many novel features: the receiving electromagnet is of peculiar construction and remarkable efficiency; the transmitting apparatus has a contrivance to prevent unintentional repetitions of a letter through the operator holding his finger too long on a key; the type-wheel has a lock for each station, to be opened by its own key, one of the letter keys of any of the instruments in the circuit. This instrument was for some years extensively used in the United States, until superseded by G. M. Phelps's [1858] modification of it, known as the "American combination printing telegraph," because it embodied part of Hughes's and part of House's instruments. With this modified form somewhat greater speed was obtained, but it was found difficult to drive, requiring the use of steam or some such motive power. In a subsequent modification introduced in 1875 an electromotor is applied to drive the printing mechanism. This allows a shorter train and stronger wheelwork to be used, secures more certain action, and involves less risk of derangement. Hughes's form was taken up by the French Government in 1860, and is still very largely in use in France.

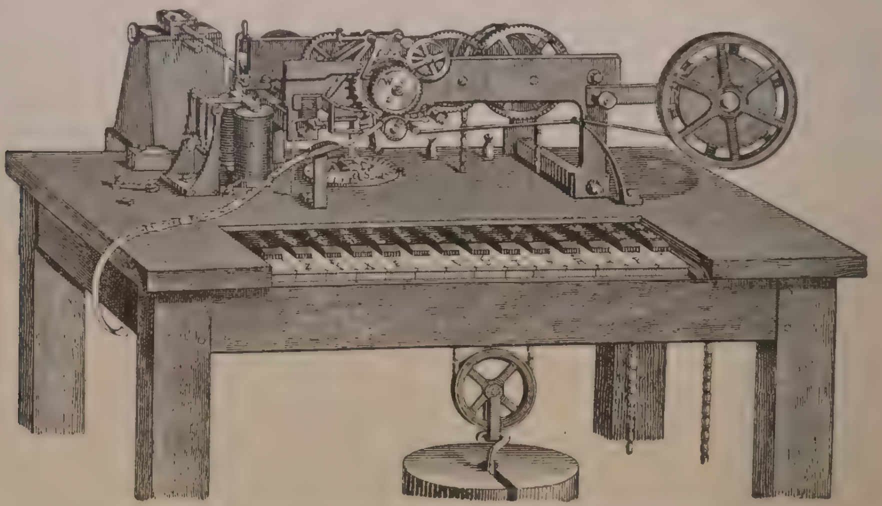

FIG. 19.—Hughes's type-printing instrument, one-tenth full size.

Stock telegraphs.

Stock and private line telegraphs constitute an important class of instruments, of which Law's "gold indicator," introduced in 1866, may be taken as the forerunner. A brief description of Calahan's stock telegraph, introduced in 1867, will give a general idea of the action of this class of instruments. The printing mechanism consists of two type-wheels, on the edge of one of which are the letters of the alphabet and on the edge of the other the numerals from 1 to 9 and fractions by eighths up to unity. The type-wheels are placed side by side, but can be turned independently of each other. Beneath them a platen is carried on one end of a lever, whose other end is attached to the armature of an electro-magnet. Between the platen and the wheels a ribbon of paper broad enough to cover the edges of both wheels is passed. The instrument is worked by three lines of wire, one for driving each type-wheel and one for printing and feeding the paper forward. The movement of the type-wheel is accomplished by an escapement acted on by closing and opening the circuit of an electromagnet. For the convenience of the sender the transmitting instrument is made in the form of two dials, each resembling the dial of an A B C instrument, round the edge of one of which letters are printed, and round the other the numerals and fractions. Mechanism is provided for opening and closing the circuit, so that by turning a handle (fixed to an axis passing through the centre of the dial) until an index attached to it points to the letter which is to be printed, the type-wheel of the receiving instrument is in the proper position to print that letter, and this is accomplished by depressing a key and closing the third circuit. The printing magnet then raises the platen and presses the paper against the type. Suppose direct United States telegraph stock is to be reported and the price is 9⅜. The operator turns the index on the letter dial to D and presses the printing key; he next turns the index to period and again presses the printing key; he then turns in succession to U, to period, to S, to period, and prints these; then he turns the index on the figure dial to 9 and prints it, lastly to ⅜ and to period and prints them. The quotation then reads on the paper ribbon D. U. S. 9⅜.

Various modifications of this instrument have since been introduced. In one form, the "universal stock printer," two lines of wire are required, and both type-wheels are driven by one wire, the printing magnet being made to change the action from one wheel to the other when the wheels are brought into a particular position. In another, "Phelps's stock printer," only one line of wire is required, a polarized armature being used for moving the type-wheels and an ordinary neutral armature for the printing. The rapid reversals which work the polarized armature do not last long enough to move the printing lever, but when a pause is made the printing mechanism is relieved and a letter printed. This instrument is similar in principle to the House apparatus and is capable of working at a considerable speed.[1]

Cowper's writing telegraph.

Cowper's writing telegraph is designed to record the message in written characters; its arrangement is as follows: Two lines of wire are connected, one with each of two small resistance slides, which are placed in such a way that the sliders move in the same plane but in directions at right angles to each other. A pen placed at the point of intersection of the lines of motion of the two sliders is connected with them in such a way that, when it is moved, as in the act of writing, each slider takes up that component of the motion which is in the direction in which it is free to move. The sliders thus vary the resistance in the line circuits by an amount proportional to the motion of the pen, and when a battery is kept joined in the circuit the current varies in the same way. The current is passed through the coils of two electromagnets at the receiving end, each capable of giving motion to a pencil in one line, at right angles to the direction of motion of the other. When the pen at the sending end is moved as in the act of writing a message the pencil at the receiving end moves in a corresponding manner on account of the variations of the current, and in this way it writes the message on a slip of paper moving beneath its point.

Open circuit, single-current system.

Methods of Working Telegraph Circuits.—(1) The arrangement on the open circuit system for single-current working is shown in Fig. 20, in which L_1 represents the line, G a simple form of galvanoscope, used simply to show that the currents are going to line when the message is being transmitted, K the transmitting key, B the battery, I the receiving instrument, and E the earth-plate. The complete circuit is from the plate E through the instrument I, the key K, and the galvanoscope G to the line L_1, then through the corresponding instruments to the earth-plate E at the other end, and back through the earth to the plate E. The earth is always, except for some special reason, used as a return, because it offers little resistance and saves the expense and the risk of failure of the return wire. The earth-plate E ought to be buried in moist earth or in water. In towns the water and gas pipe systems form excellent earth-plates. It will be observed that the circuit is not in this case actually *open*; the meaning of the expression "open circuit" is "no battery to line." Under normal circumstances the instruments at both ends are ready to receive, both ends of the line being to earth through the receiving instruments. A signal is sent by depressing the key K, and so changing the contact from *a* to *b*, and thus putting the battery to line. On circuits where the traffic is small it is usual to make one wire serve several stations. The connections at an intermediate or wayside station are shown at W. S is a switch, consisting of three blocks of brass fixed to an insulating base. W may be made the terminal station of L_1 by inserting plug 3, and of L_2 by inserting plug 2, or the instruments may be cut out of circuit by inserting plug 1. In ordinary circumstances the messages from all stations are sent through the whole line, and thus the operator at any station may transmit, if the line is free, by manipulating his key. The greatest inconvenience of this system arises from the varying strength and resistance of the batteries used at the different stations. As, however, delicate recording instruments are seldom required on such circuits little difficulty is experienced.

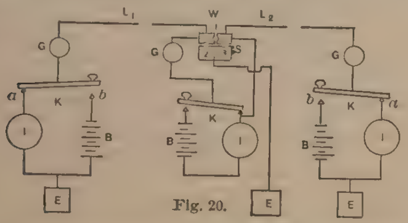

Fig. 20.

Positive and negative current.

(2) The connections for positive and negative current or single-needle working on open circuit are shown in Fig. 21, in which all the letters have the same meanings as before. But N is a single needle instrument, and K is a reversing key. The levers 1 and 2 press against the stops *a* when the line is free; hence the line is to earth at both ends. But, if lever 1 is depressed, one pole of the battery is put to line; if 2 is depressed, the other pole is put to the line. In this way the needles of the receiving instrument may be made to turn to either left or right; and, if we call a motion to the left a dot and a motion to the right a dash, the Morse alphabet may be read from these motions. The connections for wayside stations are illustrated at W, and will be readily understood from the description given under single-current working above.

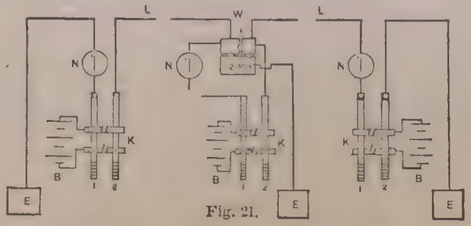

Fig. 21.

Double current.

(3) When the line consists in whole or in part of underground or submarine cable the capacity causes a very considerable diminution in the speed of working. This is to some extent got over by putting the earth connection in the middle of the battery and using double the number of cells, as shown in Fig. 22. The stop *a* of the key K is connected through a switch S with one pole of the battery B, and the stop *b* in the usual way with the other pole. Suppose the arm *c* of the switch S to be in contact with 2; then when the key is manipulated it sends alternately positive and negative currents into the line. If the positive is called the signalling current, the line will be charged positively each time a signal is sent; but as soon as the signal is completed a negative charge is communicated to the line, thus hastening the discharge and the return of the relay lever to its insulated stop. This method of working has been already referred to in connexion with Wheatstone's automatic system.

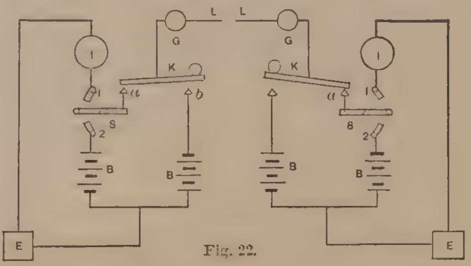

Fig. 22.

Closed circuit system.

The connections for single-current working on this system are illustrated in Fig. 23. It differs from the open circuit in only requiring one battery (although, as in the figure, half of it is often placed at each end), in having the receiving instrument between the line and the key, and in having the battery continuously to the line. The battery is kept to the line by the bar *c*, which short-circuits the keys. When signals are to be sent from either station the operator turns the bar *c* out of contact with the stop *b*, and then operates precisely as in open circuit sending. This system is more expensive than the open circuit system, as the battery is always at work; but it offers some advantages on circuits where there are a number of intermediate stations, as the circuit is under a constant electromotive force and has the same resistance no matter which station is sending or re-

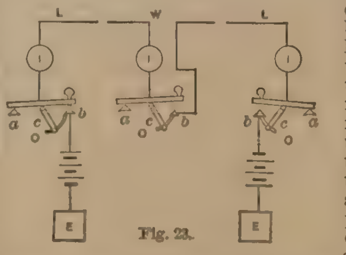

Fig. 23.

---

[1] For these and other type-printing instruments, see Prescott's *Electricity and the Electric Telegraph.*

ceiving. The arrangement at a wayside station is shown at W. When the circuit is long and contains a large number of stations, the sending battery is sometimes divided among them in order to give greater uniformity of current along the line. When only one battery is used the current at the distant end may be considerably affected by the leakage to earth along the line.

Relay working.

In working long circuits with ordinary instruments inconveniently high battery power is required in order to send sufficient current to produce the signals. In such cases it is usual to employ a local battery to produce the signals and to close the local battery circuit by means of a delicate circuit-closing apparatus called a *relay*, which is a very delicate electromagnetic key having its lever attached to the armature of the magnet. The arrangement at a station worked by relay is shown in Fig. 24, where L is the line of wire, joined through the key K to one end of the coil of the relay magnet R, the other end of which is put to earth. When a current passes through R the armature A is attracted and the local circuit is closed through the armature at *b*. The local battery B_1 then sends a current through the instrument I and records the signal. In the form of relay indicated in the figure the armature is held against the stop *a* by a spring S. In some cases—as, for example, in Siemens's polarized relay, shown in Fig. 25—the armature *a* is put in contact through the pivot *h* with one pole N of a permanent magnet *m*, the other pole *s* of which is fixed to the yolk *y* of a horse-shoe electromagnet M. The armature is placed between the poles of the electromagnet, a little nearer one pole than the other, so that the magnetic attraction holds the contact lever against the insulated stop without the aid of a spring. This form of relay only answers to currents in one direction, but it is capable of giving great sensibility, and for some purposes—for instance, in some methods of quadruplex working—its directional character is an advantage.

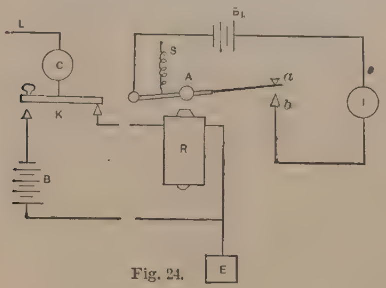

Fig. 24.

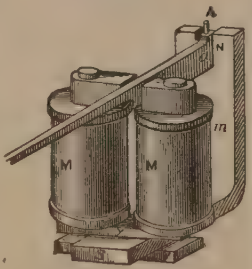

Fig. 25.—Siemens's polarized relay.

Translation.

Translation.—In a precisely similar manner a relay may be made to re-transmit automatically the message over another line, or, what is the same thing, over a continuation of the same line when the whole length is too great for direct working. It is not usual in practice to employ the delicate receiving relay for re-transmitting the message, but it is made to work a coarser instrument, which takes the place of the sounder, or, it may be, the sounder itself, in the local circuit. It is clear that one receiving relay may be used to work a number of re-transmitting keys in the same local circuit, and hence to distribute a message simultaneously over a number of branch lines from a central station.

Duplex.

Duplex, Quadruplex, and Multiple Telegraphy.—Duplex telegraphy consists in the simultaneous transmission of two messages, one in each direction, over the same wire. The solution of this problem was attempted by Gintl of Vienna in 1853 and in the following year by Frischen and by Siemens and Halske. Within a few years several methods had been proposed by different inventors, but none were at first very successful, not from any fault in the principle, but because the effect of electrostatic capacity of the line was left out of account in the early arrangements. The first to introduce a really good practical system of duplex telegraphy, in which this difficulty was sufficiently overcome for land line purposes, was J. B. Stearns of Boston (Mass.).[1] In order that the line between two stations S_1 and S_2 may be worked on the duplex system it is essential that the receiving instrument at S_1 shall not be acted on by the currents sent into the line at S_1, and similarly that the currents sent into the line at S_2 shall not act on the receiving instrument at S_2, while at the same time these currents must act on the instruments at S_2 and S_1 respectively. The two methods most commonly employed are the following:

Differential method.

(1) In Fig. 26 B is the sending battery, B_1, a resistance equal to that of the battery, R a set of resistance coils, and C a condenser. Suppose the key at station S_1 to be depressed; then a current flows into the line through circuit 1, and to earth through circuit 2. Now, if both these currents pass, as indicated in the figure, round the electromagnet of the receiving instrument, but in opposite directions, and if their strengths are properly adjusted, no effect will be produced on that instrument. At station S_2, however, the current flows to earth, partly through circuit 1 and partly through circuit 2, but in the same direction round the coils of the receiving instrument. Hence, if the current is strong enough, the receiving instrument at S_2 will be set in action. Similarly the depression of the key at S_2 can be made to produce a signal at S_1 and yet have no effect on the instrument at S_2. The necessary and sufficient condition is that the currents in circuits 1 and 2 at the sending station shall at all times bear a certain fixed ratio to each other, depending on the coils of the receiving instrument at that station. If for simplicity we suppose the resistance of the line to be constant and not to be affected by the transmitting apparatus, and to be of zero electrostatic capacity, the fixed ratio may be obtained by adjusting R in the auxiliary circuit 2. In actual practice the line has capacity, and this is compensated for by supplying to R from the condenser C capacity equivalent to that of the line. C should be of such a form that the capacity in the circuit can be varied, and it must have the same inductive retardation as the line; that is to say the capacity must be distributed along the resistance R in a manner equivalent to that in which the capacity of the line is distributed along its resistance. A rough approximation to this adjustment will answer the purpose for ordinary land line working, but for submarine cable work a very accurate adjustment is necessary. In order that the manipulation of the key may not affect the resistance of the line, the resistance between the point D and E should be as nearly as possible the same for all positions of the key. This implies that the keys shall not at any time break circuit, nor make contact on both the front and the back stops for more than an instant, for an instantaneous break of the circuit would affect the signals being received from the other station. The principle of the "continuity preserving key," used for duplex working, will be understood from the figure. So long as the key is not depressed the line is kept to earth through the resistance B_1; when the key is pushed down it suddenly changes to the battery B, being at the transition in contact with both B and B_1. This produces very little disturbance, because the key is moving quickly at that part of its stroke, and the resistance of the line and receiving instrument is generally much higher than that of B_1. This is called the "differential method." The principle was first enunciated by Frischen; but its present condition is the result of the labors of a large number of experimenters, among whom may be mentioned Siemens and Halske, Stark, Edlund, Gintl, Nyström, Preece, Nedden, Farmer, Maron, Winter, Stearns, and Muirhead.

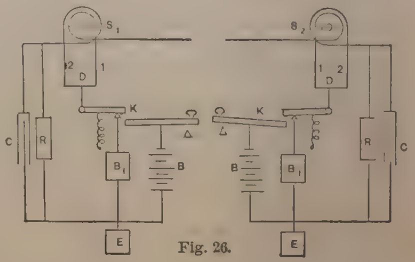

Fig. 26.

Bridge method.

(2) The second method to which we may here refer is known as the "bridge method" from the similarity of the arrangement (see Fig. 27) to that of the Wheatstone bridge. Instead of sending the currents in the two branches of the divided circuit DP

---

[1] [This duplex method was produced in 1858 and is also called the Franklin.—AM. ED.]

and DQ through the two coils of a differentially wound relay or receiving instrument, as in Frischen's method, two resistances *a* and *b* are inserted and the instruments are joined between P and Q. It is clear that if the difference of potential between P and Q is unaffected by closing the sending key K no change of current will take place in the instrument circuit. The relative potential of P and Q is not affected by the manipulation of K if the resistance *a* is to that of *b* as the resistance of L is to that of R; hence that is the arrangement used. The same remarks with regard to retardation and capacity that were made when describing the differential method apply here also. One very great advantage in this method is that the instrument used between P and Q may be of any ordinary form.

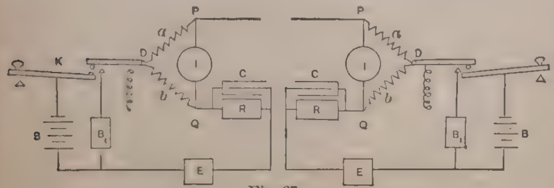

Fig. 27.

Most important cables, such as those of the Eastern Telegraph company and the various Atlantic cables, are worked duplex on Muirhead's plan. What may be called a mechanical method of duplexing a cable was described by Sir W. Thomson in a patent taken out by him in 1858. In this, as in the ordinary methods, a differentially wound receiving instrument was used, one coil being connected with the cable and the other with the earth; but it differed from other methods in requiring no "artificial" or model cable. The compensation was to be obtained by working the slides of a resistance slide included in the circuit of the compensating coil, either by the sending key or by clockwork relieved by the key, so as to vary the resistance in that circuit according to any law which might be required to prevent the receiving instrument being affected by the outgoing current. Four years later Varley patented his model cable, which was the first near approach to a successful solution of the duplex problem on the principle now adopted. It was not, however, a sufficiently perfect representation of a laid cable to serve for duplexing cables of more than a few hundred miles in length.[1]

By an interesting modification of the bridge method, which has been applied with excellent results by Dr. Muirhead to submarine work, condensers are substituted for *a* and *b*, one being also placed in the circuit between P and Q. In this case no current flows from the battery through the line or instruments, the whole action being inductive. As we have already stated, the distribution of the capacity along the resistance R must in submarine cable work be made to correspond very accurately with the distribution of the capacity along the resistance of the cable. This is accomplished by Dr. Muirhead in the following manner. One side of a sheet of paraffined paper is covered with a sheet of conducting substance, say tinfoil, and over the other side narrow strips of the same substance are arranged gridironwise to form a continuous circuit along the strip. The breadth and thickness of the strip and the thickness of the paraffined paper are adjusted so that the relative resistance and capacity of this arrangement are the same as those of the cable with which it is intended to be used. A large number of such sheets are prepared and placed together, one over the other, the end of the strip of the first sheet being connected with the beginning of the strip of the second, and so on to the last sheet, the whole representing the conductor of the cable. In the same way all the conducting sheets on the other side of the paper are connected together and form the earth-plate of this artificial cable, thus representing the sea. The leakage through the insulator of the cable is compensated for by connecting high resistances between different points of the strip conductor and the earth coating. Faults or any other irregularity in the cable may be represented by putting resistances of the proper kind into the artificial line. This system of duplexing cables has proved remarkably successful.

Quadruplex.

Quadruplex telegraphy consists in the simultaneous transmission of two messages from each end of the line. The only new problem introduced is the simultaneous transmission of two messages in the same direction; this is sometimes called "diplex transmission." The solution of this problem was attempted by Dr. J. B. Stark of Vienna in 1855, and during the next ten years it was worked at by Bosscha, Kramer, Maron, Schaak, Schreder, Wartmann, and others. The first to attain success was Edison (1874), and his method with some modifications is still used. One of the latest arrangements is shown in Fig. 28, a brief description of which will indicate the general principle involved. K_1 and K_2 are two transmitting keys the nature of which will be understood from the illustration; R_1 and R_2 are two differentially wound polarized relays, both of which are supposed to respond to positive currents and to be held against their back-stops by negative currents. When neither key is depressed a current, which for convenience we call -4, flows to the line; this is sufficient to overcome the pull of the spring T in the relay R_1 (the receiving instruments are supposed to be at the other end of the line) and hence the levers of both relays are held against their back-stops. When K_1 is depressed a current -1 is sent to the line, and, this being too weak to overcome the spring T, the lever of R_1 moves into contact with the auxiliary lever *l* and closes the circuit of the sounder S_1. When K_2 only is depressed a current $+4$ is sent to the line. This acts on both relays, but is powerful enough to overcome the pull of the spring T_1, and so to move the lever *l* and break the circuit of the sounder S_1 before it has time to act. Thus K_2 acts on the sounder S_2 but not on the sounder S_1. When both keys are depressed a current $+1$ is sent into the line. This is sufficient to move the lever of R_1 into contact with *l* but not to overcome the pull of T_1, and hence the circuit of sounder S_1 is closed; it is also sufficient to move the lever of R_2 and close the circuit of S_2. When therefore both keys are down the sounders S_1 and S_2 at the other end of the line are both set in action; the first responds to K_1 and the second to K_2. Thus all the conditions for the simultaneous transmission of two messages are provided for. It is not necessary to enter again into the question of continuity at the different positions of the keys. The figure illustrates how this diplex system may be duplexed, and hence how quadruplex working can be obtained. It is only necessary to wind the coils of the relay magnets differentially, when, by means of a precisely similar arrangement to that used for simple duplex, the instruments at the sending station are left unaffected by the outgoing currents, but are affected by the incoming currents. The method here indicated is on the differential principle; but it is scarcely necessary to say that the bridge method is equally applicable. A combination of the bridge and the differential methods has been used by Prescott and Smith, and possesses some advantages in certain cases. It is impossible in this article to go into the great variety of detail in arrangement and method with which it is possible to obtain good results.

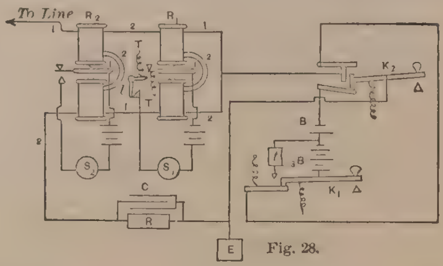

Fig. 28.

Multiple.

The several methods that have been proposed for the transmission of a number of messages in one direction on the same wire are reducible to two classes. In one the time which a revolving contact slider takes to make one revolution is divided into as many intervals as there are sets of sending and receiving instruments on the line, and by means of it the current is closed through the different sets of apparatus in succession. This implies the synchronous movement of the revolving sliders at the two ends of the line. In a sense this may be said to be simultaneous transmission; all the messages are being sent at the same time, but the progress of any one message is slower than it would be if it alone was occupying the whole line in the ordinary way. The method possesses some advantages when the line is capable of being worked at a higher speed than a single operator can attain, or when one of the stations can advantageously be used as a distributing station, for in that case one set of apparatus may be used as an automatic distributor. Multiple telegraphy on this plan was proposed by Thomson in 1858.[2] A very complete set of apparatus for the purpose was shown by Meyer at the Vienna exhibition of 1873.[1] Delaunay's multiple telegraph is the most recent development of the system, and has been lately adopted on some circuits in Great Britain.[2]

---

[1] See De Sauty, *Journ. Soc. Tel. Eng*, vol. ii. 1873.

[2] *Tel. Journ.*, September, 1886.

In the other class there are joined to the two ends of the line of wire a number of branch circuits, in each of which a set of transmitting and receiving apparatus is included. In the circuit, between the line and each of the sending keys, an electromagnetic vibrator is placed so as to open and close the circuit a great number of times during each signal. The vibrators in the key circuits at one end of the line have all different and, if possible, relatively incommensurable periods. The receivers at the other end of the line consist of a corresponding set of electromagnetic vibrators, mounted on resonators and having exactly the same vibrational periods as those in the key circuits at the sending end. When any one of the keys is manipulated the currents sent into the line have such a pulsatory character that they only affect the receiver, which is capable of vibrating freely in unison with these pulsations. When a number of keys are manipulated at the same time the receivers analyze the resultant wave, each picking out its own component, thus separating the different messages. The "harmonic telegraph" of Mr. Elisha Gray [1876] of America, is a good example of this class.

Working of Submarine Cables.—The arrangement of the apparatus for working some of the most recent cables is shown in Fig. 29. The cable is supposed to be worked duplex; but if S, C_1, C_2, and AC are removed and the key connected directly with C_3, the arrangement for simplex working is obtained. The apparatus consists of a sending battery B, a reversing transmitting key K, a slide of small resistance S, three condensers C_1, C_2, C_3, an artificial cable AC, the receiving instruments I and G, and one or more resistances R for adjusting the leakage current. The peculiar construction of AC has been already referred to. The conductor of the cable is practically insulated, as the condensers in the bridge have a very high resistance; hence no appreciable current ever flows into or out of the line. Two receiving instruments, a siphon recorder and a mirror galvanometer, are shown; one only is absolutely necessary, but it is convenient to have the galvanometer ready, so that in case of accident to the recorder it may be at once switched into circuit by the switch *s*. When one of the levers of K is depressed, the condenser C_1 and the cable, and the condenser C_2 and the artificial cable, are simultaneously charged in series; but, if the capacity of C_1 bears the same proportion to the capacity of the cable as the capacity of C_2 bears to the capacity of the artificial cable, and if the other adjustments are properly made, no charge will be communicated to C_3. After a very short interval of time, the length of which depends on the inductive retardation of the cable, the condensers corresponding to C_1 and C_3 at the other end begin to be charged from the cable, and since the charge of C_3 passes through the receiving instrument I or G the signal is recorded. The charging of C_3 at the receiving end will take place, no matter what is the absolute potential of the condensers, consequently the incoming signals are not affected by those which are being transmitted from that end. In actual practice the receiving instrument is so sensitive that the difference of potential between the two coatings of the condenser C_3 produced by the incoming signal is only a very small fraction of the potential of the battery B. When the key is relieved the condensers and cables at once begin to return to zero potential, and if the key is depressed and relieved several times in rapid succession the cable is divided into sections of varying potential, which travel rapidly towards the receiving end, and indicate their arrival there by producing corresponding fluctuations in the charge of the condenser C_3. All cables of any great length are worked by reverse currents, the single needle alphabet being used: that is to say, currents in one direction indicate dots and in the other direction dashes.

Con-
nections.

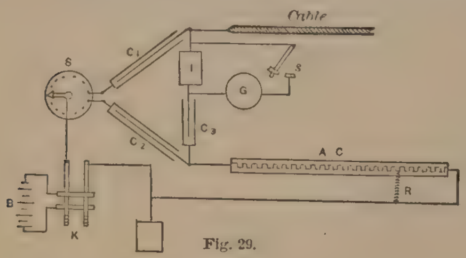

Fig. 29.

The following descriptions of the mirror galvanometer and the siphon recorder are, with some slight alteration, taken from a lecture delivered by Sir W. Thomson before the Institution of Engineers and Shipbuilders in Scotland.[3]

Mirror galvanometer.

(1.) The instrument first used for receiving signals through a long submarine cable (the short-lived 1858 Atlantic cable) was the mirror galvanometer,[4] which consisted of a small mirror with four light magnets attached to its back (weighing in all less than half a grain), suspended by means of a single silk fibre within the hollow of a bobbin of fine wire,—a suitable controlling magnet being placed adjacent to the apparatus. The action of the instrument is as follows: On the passage of a current of electricity through the fine wire coil the suspended magnets with the mirror attached tend to take up a position at right angles to the plane of the coil, and are deflected to one side or the other according as the current is in one direction or the other. Deflections to one side are interpreted as dots and to the other side as dashes, and the messages are transmitted in accordance with the international Morse code of signals.

Spark recorder.

(2.) The spark recorder in some respects foreshadowed the more perfect instrument—the siphon recorder—which was introduced some years later. Its action was as follows: To an indicator, suitably supported, a to-and-fro motion was given by the electro-magnetic actions due to the electric currents constituting the signals. The indicator was connected with a Ruhmkorff coil or other equivalent apparatus, designed to cause a continual succession of sparks to pass between the indicator and a metal plate situated beneath it and having a plane surface parallel to its line of motion. Over the surface of the plate and between it and the indicator there was passed, at a regularly uniform speed, in a direction perpendicular to the line of motion of the indicator, a material capable of being acted on physically by the sparks, either through their chemical action, their heat, or their perforating force. The record of the signals given by this instrument was an undulating line of fine perforations or spots, and the character and succession of the undulations were used to interpret the signals desired to be sent.

Siphon recorder.

(3) The latest form of receiving instrument for long submarine cables is the siphon recorder, for which Sir W. Thomson obtained his first patent in 1867. Within the three succeeding years great improvements were effected on it, and the instrument has since that date been exclusively employed in working most of the more important submarine cables of the world,—indeed all except those on which the mirror galvanometer method is in use. In the siphon recorder (see Fig. 30) the indicator consists of a light rectangular

signal coil of fine wire, suspended between the poles of two powerful electromagnets M, M so as to be free to move about its longer axis, which is vertical, and so joined that the electric signal currents through the cable pass through it. A fine glass siphon tube is suspended with freedom to move in only one degree, and is connected with the signal-coil and moves with it. The short leg of the siphon tube dips into an insulated ink-bottle, so that the ink it contains becomes electrified, while the long leg has its open end at a very small distance from a brass table, placed with its surface parallel to the plane in which the mouth of the leg moves, and over which a slip of paper may be passed at a uniform rate, as in the spark recorder. The ink is electrified by a small induction electrical machine E placed on the top of the instrument; this causes it to fall in very minute drops from the open end of the siphon tube upon the brass table or the paper slip passing over it. When, therefore, the signal-coil moves in obedience to the electric signal currents passed through it, the motion communicated to the siphon is recorded on the moving slip of paper by a wavy line of ink-marks very close together. The interpretation of the signals is according to the Morse code,—the dot and dash being represented by deflections of the line of dots to one side or other of the centre line of the paper. A very much simpler form of siphon recorder has been devised and brought into use within the last few years. Instead of the electromagnets, two bundles of long bar-magnets of square section and made up of square bars of glass-hard steel are used. They are supported vertically on a cast-iron socket, and on the upper end of each is fitted a soft iron shoe, shaped to concentrate the lines of force and thus produce a strong magnetic field in the space within which the signal-coil is suspended. Instruments of this kind have been made to work both with and without electrification of the ink. Without electrification the instrument (see Fig. 31) is very simple and compact, and capable of doing good work on cables 500 or 600 miles long. When constructed for electrification of the ink they are available for much greater lengths, but for cables such as the Atlantic the original form is still used. The strongest magnetic field hitherto obtained by permanent magnets (of glass-hard steel) is about 3000 C.G.S. With the electromagnets used in the original form of siphon recorder a magnetic field of about or over 5000 C.G.S. is easily obtained. Fig. 32 shows a facsimile of part of a message received and recorded by a siphon recorder, such as that of Fig. 30, from one of the Eastern Telegraph Company's cables about 830 miles long.

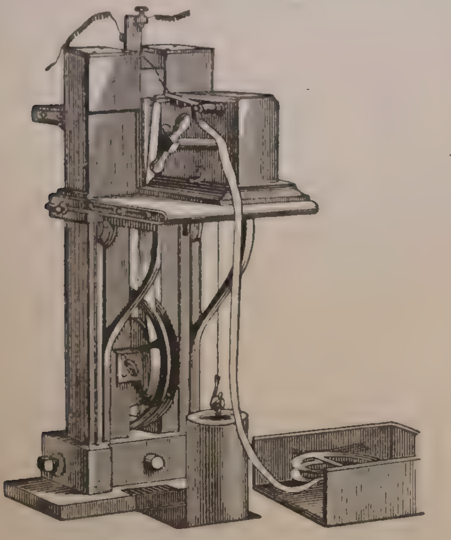

FIG. 31.—Siphon recorder.

Automatic curb sender.

(4) The automatic curb sender was designed by Sir W. Thomson for the purpose of diminishing the effect of inductive embarrassment in long cables. In ordinary hand-sending the end of the cable is put to one or the other pole of the battery and to earth alternately, the relative time during which it is to battery and to earth depending to a great extent on the operator. By the automatic curb sender the cable is put to one or the other pole of the battery and then to the reverse pole for definite proportionate times during each signal. The cable is thus charged first positively and then negatively, or *vice versa*, for each signal. This method not only facilitates the discharge of the cable, and so accelerates the return of the index of the receiving instrument to zero, but provides the means of sending positive and negative currents into the cable at the proper times and for the proper intervals. The action of the instrument is regulated, like that of Wheatstone's automatic transmitter, by a perforated slip of paper. The arrangement of the perforations and the method of using the paper slip are, however, quite different. The paper is fed forward by a central row of holes, which are therefore continuous. The dots and dashes of the message are represented by the side rows of holes; but the two currents required for a dot are produced wholly by one hole on one side, and those for a dash by one hole on the other side. The perforated slip is exactly similar to the message written by the siphon recorder, the side holes occupying the same relative positions as the loops to one side or other of the central line in the record. As the side holes reach a certain point in their passage through the instrument they allow the end of one or the other of two levers to fall; the other end of the lever lifts a light contact spring, forming one lever of a reversing key, and makes electrical connection between the battery and another set of springs, which also form the levers of a reversing key. The spring is held up by a flange on the edge of a revolving wheel passing under it, during the time required by the paper to advance through the distance between two central holes. During this interval the current is reversed at the proper time by a pair of adjustable cams fixed to the same spindle as the flanged wheel. This method of transmission has been found quite successful, though it has not been brought into use, as hand-sending has hitherto proved sufficient for the work required.

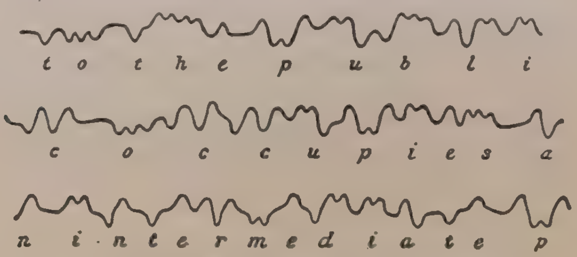

FIG. 32.—Facsimile of siphon recorder message.

Speed of signalling.

Speed of Signalling.—The mathematical theory of the speed of telegraphic signalling was given in a paper on "The Theory of the Electric Telegraph" communicated by Sir W. Thomson[1] to the Royal Society in 1855. He shows that, if k be the wire resistance, c the capacity per unit length, and l the total length of the line, the current at the receiving end at any time t after the application of the battery at the sending end is given by the equation

$$C_t = C\left\{1 - 2(\varepsilon - \varepsilon^4 + \varepsilon^9 - \varepsilon^{16} + \text{etc.})\right\},$$

where C is the maximum current which the battery is capable of maintaining through the line, and ε is equal to $(\frac{3}{4})^{\frac{t}{a}}$ when a is equal to $kcl^2 \log_e(\frac{4}{3})/\pi^2$. The number $\frac{4}{3}$ is quite arbitrary; it is chosen because it makes a nearly equal to the time required for the current to become sensible at one end of the line after the battery has been applied to the other end. The number $10^{\frac{1}{10}}$, which is more convenient for calculation and which does not differ greatly from $\frac{4}{3}$, was subsequently adopted by Sir W. Thomson, and also by Professor Jenkin.[2] The equation may be written

$$C_t = C\left\{1 - 2\left(e^{-\pi^2 t/kcl^2} - e^{-4\pi^2 t/kcl^2} + e^{-9\pi^2 t/kcl^2} - \text{etc.}\right)\right\},$$

which shows plainly how the current is affected by the length, the resistance, and the capacity of the line.

It is evident from this equation that a finite time is required after the battery has been applied at the sending end for the current to become sensible at the receiving end, the interval being practically equal to a, and also that for similar actions the intervals between operations for one line must be to the corresponding intervals for another line directly as the values of a or of kcl^2

---

[1] See his *Mathematical and Physical Papers*, vol. ii. p. 61.

[2] See Jenkin, *Electricity and Magnetism*, p. 331.

for the two lines. We see, therefore, that for lines of the same type, worked in the same manner, the speed of working will be inversely as the square of the length of the line, or, if the type varies, inversely as the product KQ, where K is the total resistance and Q the total capacity of the line. The interval *a* must not be confounded with the time required for each signal: it is a measure of the slowness of transmission; but the number of signals which can be received in a given time, on any one line, depends on the method of working and on the sensibility of the instruments employed. The ratios of the number of signals which can be sent over different lines in a stated time are the same as the ratios of the values of *a* for these lines. The value of *a* for the different Atlantic cables varies between a fifth and a quarter of a second, and, as the time required for the current to reach 90 per cent. of its maximum value is ten times *a*, an instrument which requires as much as 90 per cent. of the full current to produce a signal and a fall to 50 per cent. between the signals could only receive about one signal every two seconds or between one and two words per minute. The instruments actually used attain to a speed of about twenty times this; but they are capable of showing distinctly a current of a ten-thousandth, or even less, of the maximum current. The value of *a* for ordinary land lines is very small, probably not exceeding the five-thousandth part of a second for a circuit 500 miles in length. The current, therefore, rises almost to its full value for each signal when the time of contact is as small as the five-hundredth part of a second, or, on the Wheatstone instrument, when the speed is about 500 words per minute. There is, however, a very sensible increase in the effective resistance of the circuit, especially when iron wire is used, when signals are sent as rapidly as 100 per second, so that higher battery power is required for fast than for slow rates of speed. The difficulty in working land lines at rates up to 300, or even more, words per minute is not to any serious extent electrical, but is in great measure due to material and magnetic inertia in the receiving instruments. Although land lines can be worked at a very high speed when the whole of the wire is insulated on poles, the rate is greatly diminished if a length of underground or of submarine cable is included in the circuit. In practice also the speed depends greatly on the position of the cable in the circuit; for example, the actual speed from Dublin to London, according to Mr. Preece, is about twice as great as that from London to Dublin. Mr. Cully states that the greatest effect is produced when the cable is in the middle of the circuit. (T. GR.)

TELEMETER, or **Rangefinder.** This is an instrument used in modern warfare to determine the distance or range to an enemy's position, in order that correct elevations may be given to guns or rifles directed against it. Telemeters have been made on three distinct principles, and classified as acoustic, optical, and trigonometrical respectively.

Acoustic telemeters record the time which elapses between seeing the flash or smoke and hearing the report of a gun, rifle, or shell, the range being given in yards as "the time in seconds + 364.6." The Boulengé telemeter is the best known of this class. It consists of a graduated glass tube filled with liquid and containing a small metal traveller. At the flash the instrument is brought to a vertical position, and the traveller starts from zero; at the detonation it is turned to a horizontal position and the traveller stops. The objections to the acoustic telemeter are that the rate of transmission of sound in air is affected by wind and other local conditions and that the instrument cannot be used until firing has commenced.

Optical or *perspective telemeters* determine the distance to any point by observing the size of some object of known dimensions, as seen in a graduated telescope. Porro's telemeter, Elliott's telescope, and Nordenfelt's macrometer illustrate the principle. The chief defect of the system is that the objects most conveniently observed—men and horses—vary considerably in size, so that the assumption of a constant dimension may be productive of error.

Trigonometrical telemeters shorten the ordinary methods of surveying by adapting them to military purposes. They are of two kinds,—field rangefinders and rangefinders for coast batteries.

(1) *Field rangefinders* exist in great variety, and differ from one another both in the trigonometrical methods pursued and in the mechanical peculiarities exhibited. The following are the common solutions of what is technically called "the range-finding triangle,"—*i.e.*, a triangle in which O (Fig. 1) is the object the distance to which is required, AOB an acute angle, and AB the base,—O being visible both from A and B. (i.) Where the base is a fixed length and the angles are variable.—A fixed base is rarely adopted except when the base forms part of the instrument, the angles being observed by powerful telescopes. The range is usually read in yards by the assistance of verniers, extreme perfection of mechanism being necessary. Many ingenious instruments of the kind have been devised, but none have as yet proved satisfactory. With a fixed base the accuracy diminishes as the range increases. (ii.) Where the base and the angles are variable.—The base angles are generally observed by instruments of the theodolite type, and the base is actually measured or found by means of a sub-base. The range is obtained by table or calculating scale. The Nolan rangefinder, which was the first telemeter used by the British artillery, was of this kind. (iii.) Where one base angle is a right angle, the other angles and base being variable.—The instrument used is generally double-reflecting of the sextant type,—the base being found as in (ii.). The most perfect example is the Watkin rangefinder, used by the British horse and field artillery. It (Fig. 2) consists of an horizon glass capable of assuming two positions, and an index glass set in a steel arm, which is worked by a movable collar on a graduated bar, and this again is moved by the turning of a graduated cylinder. O (Fig. 3) being the object, the observer sets up a picket at A, and with the instrument at zero (the horizon glass being inclined 45° to the index glass) finds the right angle at the point C. A sub-base AB of 6 yards is then set off, and (with glasses set parallel and the sliding collar at 6) the observer reflects B upon A by turning the cylinder, which is thus made to record the base AC in yards. This reading being set on the graduated bar by moving the sliding collar, the observer proceeds to A, and from there reflects C upon O, which causes the range to be given in yards on the cylinder. In this operation the position of the sliding collar regulates the movement of the steel bar so that the number of turns of the cylinder is always a true

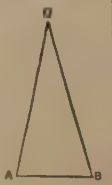

Fig. 1.

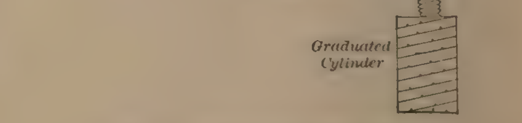

Fig. 2.—Watkin field rangefinder.

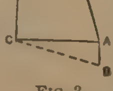

Fig. 3.

measure of the range OC, whatever the length of the base AC. (iv.) Where the angles are fixed and the base is a measure of the range.—The base points are determined by the use of prisms or of mirrors reflecting the particular angles adopted. The base is measured or found by a subsidiary triangle, and multiplied by a constant to give the range. The Weldon rangefinder, recently issued to the British infantry, is on this principle. It consists of three prisms, and is generally used as follows: O (Fig. 4) being the object and D a convenient distant point, the observer makes with the first prism the right angle OAD. He then retires in the direction DA till the second prism records the angle OBD = 88° 51′ 15″, when the range = 50 × AB. If it is inconvenient to measure AB, the observer can retire from B in the line OB until the third prism records the angle OCA = 74° 53′ 15″, when the range = 200 × BC. The prisms must be held in the plane of the objects and looked into at the same point. This rangefinder is very simple and portable, but is frequently inapplicable on hilly or broken ground, and does not possess great accuracy.

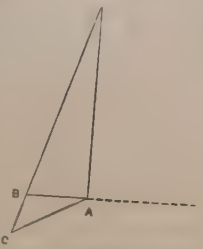

FIG. 4.—Weldon rangefinder.

The merits of different field rangefinders depend mainly upon the balance of advantages they offer with respect to accuracy, suitability to variety of ground, simplicity, portability, and durability, these conditions being of a more or less conflicting character. The following are recognized principles: (1) the naked eye cannot with certainty appreciate less than one minute difference of angle, therefore telescopic power is necessary in proportion as the base is short compared with the range; (2) telescopes of high power cannot be steadied by hand alone; (3) the longer the base the more inconvenient are any restrictions as to its length or direction; (4) it is a disadvantage to be compelled to traverse the line joining base points; (5) the longest base which it is convenient to measure by hand is that length of measuring line which can be stretched tight in a high wind.

(2) *Rangefinders for Coast Batteries.*—Rangefinding is less adapted to the requirements of coast defence than "position finding,"—a method which furnishes every gun with its proper training and elevation so that it can be fired without sighting the target. Rangefinders are, however, sometimes employed. The most worthy of notice is the Watkin depression rangefinder used by the British artillery in coast batteries. The instrument resembles in principle the Watkin field rangefinder, the height above the sea-level being a vertical base. The range is found by observing the angle of depression to the object. This is done by a powerful cross-wire telescope, which forms part of the instrument. The fastest steamer can be continuously followed, and even the successive grazes of shot and shell can be observed. The instrument is levelled upon a tripod stand. When necessary, it finds its exact height in feet above the water-level in any state of tide by reference to a datum distance, and it records the range in yards automatically on a graduated cylinder. An interesting contrivance combining telemeter and gun-sight, applicable to guns in permanent emplacements over non-tidal waters, has been tried in Italy. By means of a cam the hind-sight of the gun is always maintained in the position necessary to give the proper elevation in firing, so that it only remains to make the sights cover the target. (A. W. W.*)

TELEPHONE.

TELEPHONY is the art of reproducing sounds at a distance from their source. The term was first used by Philip Reis of Friedrichsdorf, in a lecture delivered before the Physical Society of Frankfort in 1861.[1] But, although this lecture and Reis's subsequent work received considerable notice, little progress was made until the subject was taken up between 1874 and 1876 by Alexander Graham Bell, a native of Edinburgh, then resident in Boston, Mass. Bell, like Reis, employed electricity for the reproduction of sounds; but he attacked the problem in a totally different manner. This will be better understood if we consider shortly on what the chief characteristics of sound depend (compare ACOUSTICS).

Characteristics of sound.

The sensation of sound is produced by rapid fluctuations in the pressure of the atmosphere on the tympanum of the ear. If the fluctuations are irregular and non-periodic, the sound is called a noise; if they are cyclic and follow a regular and sufficiently rapid periodic law, the sound is musical. In connection with the present subject it is important to notice the three characteristics of a musical sound, namely, *pitch*, *loudness*, and *quality*. The pitch of a musical sound depends on the number of cycles passed through by the fluctuations of the pressure per unit of time; the loudness depends on the amount or the amplitude of the fluctuation in each cycle; the quality depends on the form or the nature of the fluctuation in each cycle. The necessary condition for a successful system of telephony is the ability to reproduce these characteristics.

I. HISTORY.

Mechanical telephone.

In 1831 Wheatstone by his "magic lyre" experiment showed[2] that, when the sounding-boards of two musical instruments are connected together by a rod of pine wood, a tune played on one will be faithfully reproduced by the other. This only answers, however, for telephoning musical sounds to short distances. Another and somewhat similar example is furnished by what has been variously designated as the "string," "toy," "lovers," and "mechanical" telephone. Two disks of thin metal, or two stretched membranes, each furnished with a mouthpiece, are connected together by a thin string or wire attached at each end to the centres of the membranes. A good example may be made with two cylindrical tin cups; the bottoms form the membranes and the cups the mouthpieces. When the connecting string is held taut and sounds, such as those of ordinary speech, are produced in front of one of the membranes, pulses corresponding to the fluctuations of the atmospheric pressure are transmitted along the string and communicated to the other membrane, which in its turn communicates them to the air, thus reproducing the sound. In both these examples all the three characteristics—pitch, relative intensity, and quality—of sound are reproduced.

Page's discovery.

Let us now return to the development of the application of electricity to telephony. In July, 1837, Dr. C. G. Page of Salem, Mass., drew attention to the sound given out by an electromagnet at the instant when the electric circuit is closed or broken, and in October of the same year he discussed, in a short article[1] entitled "Galvanic Music," the musical note produced by rapidly revolving the armature of an electromagnet in front of the poles. Experiments bearing on this subject were subsequently made by a great number of investigators.[2] Page's discovery is of considerable importance in connection with the theory of action of various forms of telephone, and was a very important feature in the early attempts by Reis to transmit music and speech. On 26th August, 1854, there appeared in *L'Illustration* (Paris) an interesting article by Charles Bourseul on the electric transmission of speech.[3] The writer recommended the use of a flexible plate at the source of sound, which would vibrate in response to the varying pressure of the air, and thus open and close an electric circuit, and of a similar plate at the receiving station, which would be acted on electromagnetically and thus give out as many pulsations as there are breaks in the current. These suggestions were to some extent an anticipation of the work of Reis; but the conditions to be fulfilled before the sounds given out at the receiving station can be similar in pitch, quality, and relative intensity to those produced at the transmitting station are not stated, and do not seem to have been appreciated.

Bourseul's suggestions.

Reis's telephone.

In Reis's lecture an apparatus was described which has given rise to much discussion as to priority in the invention of the telephone. The instrument was described in over fifty publications[4] in various countries, and was well known to physicists previous to Bell's introduction of the electric telephone as a competitor with the electric telegraph. Reis caused a membrane to open and close an electric circuit at each vibration, thus transmitting as many electric pulses through the circuit as there were vibrations in the sound. These electric pulses were made to act on an electromagnet at the receiving station, which, in accordance with Page's discovery, gave out a sound of a pitch corresponding to the number of times it was magnetized or demagnetized per second. Reis's object was to reproduce at a distance not only music but also human speech; but that he did not wholly succeed is clear from the following extract from his lecture: "Hitherto it has not been possible to reproduce human speech with sufficient distinctness. The consonants are for the most part reproduced pretty distinctly, but not the vowels as yet in an equal degree." Considering the time at which he wrote, Reis seems to have understood very well the nature of the vibrations he had to reproduce, but he failed to comprehend how they could be reproduced by electricity. His fundamental idea—the interruption of the current—was a fatal mistake, which was not at the time properly understood. The suggestion of Bourseul and the experiments of Reis are founded on the idea that a succession of currents, corresponding in number to the successive undulations of the pressure on the membrane of the transmitting instrument, could reproduce at the receiving station sounds of the same character as those produced at the sending station. Neither of them seemed to recognize anything as important except pitch and amplitude, and Reis thought the amplitude was to some extent obtained by the varying length of contact in the transmitting instrument. This might possibly be to a small extent true; but, considering the small capacity of the circuits he used and the nature of his receiving instrument, it is hardly probable that duration of contact sensibly influenced the result. The quality of the sounds was to some extent also reproduced; but, judging from the results of recent telephone investigation, it is highly probable that this was due, not to the varying duration, but to the varying firmness of the contact. Since the effect of the degree of contact has, through the researches of Bell, Berliner, Edison, Hughes, Elisha Gray, and others, become generally understood, it has become easy to make instruments very similar to those of Reis; and even his instruments, with slight modification, can be made to speak fairly well. The accidental transmission of words by Reis, the occasional recognition of the voice of a singer, and other instances of the transmission of quality were no doubt due to this element, the existence of or the necessity for which was never, so far as the present writer knows, hinted at by Reis.

Bell's researches.

The next worker at the telephone, and the one to whom the present great commercial importance of the instrument is due, was Bell. His aim was the production, by means of the undulations of pressure on a membrane caused by sound, of an electric current the strength of which should at every instant vary directly as the pressure varied.[5] His first idea seems to have been to employ the vibrations of the current in an electric circuit, produced by moving the armature of an electromagnet included in the circuit nearer to or farther from the poles of the magnet. He proposed to make the armature partake of the vibrations of the atmosphere either by converting it into a suitable vibrator or by controlling its vibrations by a stretched membrane of parchment. In the early trials the armature had the form of a hinged lever of iron carrying a stud at one end, which pressed against the centre of a stretched membrane. The experiments with this form were not successful, and, with the view of making the moving parts as light as possible, he substituted for the comparatively heavy lever armature a small piece of clock spring, about the size of a sixpence, glued to the centre of the diaphragm. The magnet was mounted with its end carrying the coil opposite, and very close to, the centre of the piece of clock spring. This answered sufficiently well to prove the feasibility of the plan, and subsequent experiments were directed to the discovery of the best form and arrangement of the parts. An increase in the size of the iron disk attached to the membrane augmented both the loudness and the distinctness of the sounds, and this finally led to the adoption of the thin iron disk now in use, which is supported round its edge, and acts as both membrane and armature. Again, the form of the opening or mouth-piece in front of the membrane exercised considerable influence on the efficiency of the instrument, and it was ultimately ascertained that a small central opening, with a thin air space extending across the face of the membrane, was best. It was also found that comparatively small magnets were sufficient, and that there was no particular virtue in the closed circuit and electromagnet, but that a small permanent magnet having one pole in contact with the end of the core of a short electromagnet, the coil of which was in circuit with the line, but which had no permanent current flowing through it, answered the purpose quite as well.[6] In fact the effect of keeping a permanent current flowing through the line and the coils of the electromagnet was to keep the core of the electromagnet magnetized. This seems to have been almost simultaneously pointed out by Bell and others who were working in conjunction with him and by Professor Dolbear. Many experiments were made for ascertaining the best length of wire to use in the coil of the transmitting and the receiving instrument; but this is clearly a question dependent to a large extent on the nature of the line and the system of working adopted.

[6] The extreme smallness of the magnets which might be successfully employed was first demonstrated by Professor Peirce of Brown University, Providence, R. I.

After Bell's success a large number of experimenters entered the field, and an almost endless variety of modifications have been described. But few possess any real merit, and almost none have any essentially new principles.[1]

Edison's transmitter and friction receiver.

A telephone transmitter and a receiver on a novel plan were patented in July, 1877, by Edison, shortly after the introduction of Bell's instruments. The receiver was based on the change of friction produced by the passage of an electric current through the point of contact of certain substances in relative motion. In one form a drum, mounted on an axis and covered by a band of paper soaked in a solution of caustic potash, is turned under a spring the end of which is in contact through a platinum point with the paper. The spring is attached to the centre of a diaphragm in such a way that, when the drum is turned the friction between the point of the spring and the paper deflects the diaphragm. The current from the line is made to pass through the spring and paper to the cylinder. Now it had been previously shown by Edison that, when a current is made to pass through an arrangement like that just described, the friction between the paper and the spring is greatly diminished. Hence, when the undulating telephonic currents are made to pass through the apparatus, the constant variation of the friction of the spring causes the deflections of the diaphragm to vary in unison with the variation of the electric currents, and sounds are given out corresponding in pitch, and also to some extent in quality, with the sounds produced at the transmitting station. A cylinder of chalk was used in some of Edison's later experiments with this receiver. The transmitter is illustrated (see Fig. 10) and described (p. 142) below.

Elisha Gray's experiments.

Experiments very similar to these of Edison were made by Elisha Gray, of Chicago, Ill., and described by him in papers communicated to the American Electrical Society in 1875 and 1878. In these experiments the electric current passed through the fingers of the operator's hand, which thus took the place of the spring in Edison's apparatus. The diaphragm was itself used as the rubbing surface, and it was either mounted and rotated or the fingers were moved over it. When the current passed, the friction was felt to increase, and the effect of sending a rapidly undulating current through the arrangement was to produce a sound. The application of this apparatus to the transmission of music is described by Gray.[2]

Dolbear's condenser telephone.

In another form of telephone, brought prominently forward by Professor Dolbear,[3] the effects are produced by electrostatic instead of electromagnetic forces, as in the Bell-telephone. Sir W. Thomson observed in 1863[4] that when a condenser is charged or discharged a sharp click is heard, and a similar observation was made by Cromwell F. Varley, who proposed to make use of it in a telegraphic receiving instrument.[5] In Dolbear's instrument one plate of a condenser is a flexible diaphragm, connected with the telephone line in such a way that the varying electric potential produced by the action of the transmitting telephone causes an increased or diminished charge in the condenser. This alteration of charge causes a corresponding change in the mutual attraction of the plates of the condenser; hence the flexible plate is made to copy the vibrations of the diaphragm of the transmitter. It is obvious that this apparatus may be used either as a transmitter or as a receiver, but that the effects must under ordinary circumstances be in either case extremely feeble.

In the Reis instruments the transmitter and receiver are separate parts, which are not interchangeable. The Bell telephone can be used either as a transmitter or as a receiver. The Edison receiver and the Dolbear condenser were only intended to be used as receiving instruments.

Liquid transmitters of Bell and E. Gray.

It was very early recognized—and, indeed, is mentioned in the first patents of Bell, and in a caveat filed by Elisha Gray in the United States patent office only some two hours after Bell's application for a patent—that sounds and spoken words might be transmitted to a distance by causing the vibrations of a diaphragm to vary the resistance in the circuit. Both Bell and Gray proposed to do this by introducing a column of liquid into the circuit, the length of the resistance of which could be varied by causing the vibrations of the diaphragm to vary the depth of immersion of a light rod fixed to it and dipping into the liquid (see Figs. 8, 9 below). This idea has been perhaps the most fruitful of any modification of telephonic apparatus introduced.

Berliner's microphone transmitter.

On 4th April, 1877, Mr. Emile Berliner filed a caveat in the United States patent office, in which he stated that, on the principle of the variation with pressure of the resistance at the contact of two conductors, he had made an instrument which could be used as a telephone transmitter, and that, in consequence of the mutual forces between the two parts of the current on the two sides of the point of contact, the instrument was capable of acting as a receiver. The caveat was illustrated by a sketch showing a diaphragm with a metal patch in the centre, against which a metal knob was lightly pressed by an adjusting screw. This seems to have been the first transmitter in which it was proposed to use the resistance at the contact of two conductors.

Edison's microphone transmitter.

Almost simultaneously with Berliner, Edison conceived the idea of using a variable resistance transmitter.[6] He proposed to introduce into the circuit a cell containing carbon powder, the pressure on which could be varied by the vibrations of a diaphragm. He sometimes held the carbon powder against the diaphragm in a small shallow cell (from a quarter to half an inch in diameter and about an eighth of an inch deep), and sometimes he used what he describes as a *fluff*, that is, a little brush of silk fibre with plumbago rubbed into it. In another form the plumbago powder was worked into a button cemented together with syrup and other substances. In the specification of the patent applied for on 21st July, 1877, he showed a sketch of an instrument which consisted of a diaphragm, with a small platinum patch in the centre for an electrode, against which a hard point, made of plumbago powder cemented together with india-rubber and vulcanized, was pressed by a long spring, the pressure of the carbon against the platinum disk being adjusted by a straining screw near the base of the spring. Subsequently he filed an application for a patent in which various forms of springs and weights assisted in maintaining the contacts and otherwise improved the instrument.

Hughes's microphone.

In the early part of 1878 Professor Hughes, while engaged in experiments upon a Bell telephone in an electric circuit, discovered that a peculiar noise was produced whenever two hard electrodes, such as two wires, were drawn across each other, or were made to touch each other with a variable degree of firmness. Acting upon this discovery, he constructed an instrument which he called a microphone,[1] and which consisted essentially (see Fig. 11) of two hard carbon electrodes placed in contact, with a current passing through the point of contact and a telephone included in the same circuit. One of the electrodes was attached to a sounding-board capable of being vibrated by sound-waves, and the other was held either by springs or weights in delicate contact with it. When the sounding-board was spoken to or subjected to sound-waves, the mechanical resistance of the loose electrode, due to its weight, or the spring, or both, served to vary the pressure at the contact, and this gave to the current a *form* corresponding to the sound-waves, and it was therefore capable of being used as a speaking-telephone transmitter.[2] The best transmitters now in use are modifications of Hughes's apparatus. A microphonic apparatus very similar to it is described in the specification of a German patent taken out by Robert Lutdge on 12th January, 1878. In this patent the action of the microphone is also described.[3]

Blake transmitter.

The next transmitter of note, introduced by Mr. Francis Blake, U. S. (see Fig. 13 below), although it does not, like the first microphones, embody anything intrinsically new, is one of the most perfect and convenient forms of microphone. It is at present almost universally used in the United States.

Modifications of Edison's transmitter.

It appears to be pretty well established that carbon in one form or another is the best material for one or both of the contacts of a microphone transmitter. When both the contacts are of carbon and the surfaces have considerable area, say from a quarter to half an inch in diameter, the sounds are loud, but have a tendency to harshness. When, as in the Blake transmitter, one of the contacts is a piece of polished gas carbon and the other a small sphere of platinum about the twentieth of an inch in diameter, the articulation is clear, but less loud. For most purposes, however, the increased clearness more than compensates for the diminished loudness. Many transmitters in actual use—as, for instance, the "Gower," largely employed in the United Kingdom—have a number of contacts. Some of these when properly adjusted are both loud and clear in their action. Although the Blake instrument is most in vogue in America, in the United Kingdom and on the Continent multiple contact microphones have found more favor. Carbon powder instruments have been to some extent used, and in one or two cases—as, for example, the Hunnings transmitter—with considerable success. The fault in most of them is the tendency of the powder to "pack," which causes the instrument to rapidly lose sensibility. In the Hunnings transmitter this difficulty is to a large extent overcome by the use of a coarse granular powder in a somewhat large cell (about an inch in diameter and from one-eighth to one-fourth of an inch deep). The front face of the cell is a piece of platinum foil, which serves both as an electrode and as a diaphragm. The cell is placed either on edge or in an inclined position when in use, the action being precisely similar to that in other transmitters. In addition to its freedom from packing, the carbon, in consequence of the inclined position of the cell, is also less liable to fall away from the electrode and break the circuit. Some packing of the powder, however, does occur, and several modifications have been proposed by Blake and others for making the sound vibrations stir the powder and keep it loose. Good results appear to have been got by placing the cell mouth downwards, the carbon powder lying on the platinum foil, and by forming the upper electrode either of wire gauze or of a perforated plate completely immersed in the powder. The sound vibrations are conveyed to the bottom of the cell by a bent tube communicating with a mouthpiece. Instruments of this class are very loud-speaking, and, therefore, very serviceable for long or disturbed circuits.

Radiophone.

The radiophone is an instrument proposed by A. G. Bell and Sumner Tainter in 1880, for utilizing radiant energy, such as light or radiant heat, for the transmission of sound. The apparatus forms a telephone transmitter of a particularly interesting kind. In the earlier papers describing it and the experiments which led to its invention it is called *photophone*, because at that time the effects were supposed to be wholly due to light. Afterwards, in order to avoid ambiguity, Bell changed the name to *radiophone* and suggested that, to distinguish between instruments depending on the different kinds of radiation, the names *photophone*, *thermophone*, etc., should be employed. He also proposed the name *spectrophone* for an application of this instrument to spectrum investigation.[4] The apparatus is founded on the discovery, made by Mr. May while carrying out experiments on selenium for Mr. Willoughby Smith, that when selenium is exposed to light its electrical resistance is very different from what it is in the dark. This discovery led to a great many interesting experiments by other investigators.[5] In thinking over this discovery in 1878 Bell conceived the idea that, if a beam of light proceeding from one station could be made to fall on a selenium plate at another station, and if its intensity could be varied by the voice of a speaker, then by connecting a telephone and a battery in circuit with the selenium plate the words spoken at the distant station would be heard in the telephone. This was found to be the case. At first, to vary the intensity of the beam, it was passed through a small opening, the width of which could be varied by the vibrations of a diaphragm against which the speech was directed. But better results were afterwards obtained when the diaphragm formed a mirror from which the beam of light was reflected. The spreading of the beam, due to the vibrations of the mirror diaphragm, served to vary its intensity (see Fig. 18 below).

Edison's phonograph.

Edison's phonograph (see Fig. 19 below) is an instrument whose action somewhat resembles that of a telephone transmitter and which has been much talked of in regard to its possible applications in telephony. It was invented shortly after the introduction of the telephone for the purpose of recording sounds, and was included in some of Edison's telephone patents as a means of working a telephone transmitter, and thus telephoning sounds which had been previously recorded on the phonograph sheets.

II. TELEPHONIC INSTRUMENTS.

One of the best-known forms of the Reis telephone is shown in Fig. 1. The transmitter consists of a box A, provided with a mouthpiece M. In the top of the box a round hole is cut and across it a membrane S of hog's bladder is stretched. A thin strip of platinum *p* fixed to the box at one side of the hole and extending to the centre of the membrane, supports at that point one foot of a light metal tripod *egf*. One of the feet, *e* or *f*, rests in a cup containing mercury, which is in metallic connection with the terminal *b*, while the end of the strip *p* is similarly in connection with the terminal *a*. The receiver consists of an electromagnet made up of a magnetizing coil H, with a stout knitting needle for a core. When in use these two instruments are joined in circuit with a battery B, so that under ordinary circumstances a continuous current is flowing through the line. Suppose a sound is then produced in front of the mouthpiece M, the successive variations in the pressure of the air are communicated to the inside of the box, and cause the membrane to vibrate in unison with the sound. Reis's theory of the action of the instrument was that at each outward impulse of the membrane the point *g* would be thrown out of contact with the plate underneath it and would thus break the circuit. There would consequently result as many breaks in the circuit as there were vibrations in the sound, and in conformity with Page's discovery, the electromagnetic receiver would give out a rapid succession of beats, which would together form a continuous sound of the same pitch as that to which the transmitter was subjected.

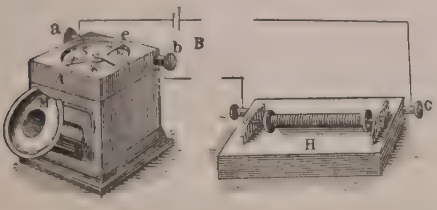

FIG. 1.—Reis's telephone.

Bell's first telephone.

Fig. 2 shows the first telephone made by Bell for transmitting speech. It consisted of a wooden frame F, to one side of which a tube T was fixed; over the end of the tube a membrane M was stretched taut by a stretching ring R. To the opposite side of the frame and with its axis in line with that of the tube T was fixed an electromagnet H, and between the membrane M and the end of the electromagnet a hinged armature A was arranged in such a way that its motions would be controlled by the membrane. The instrument was joined in circuit with a battery and another similar instrument placed at a distance. A continuous current was made to flow through the circuit, which kept the electromagnet magnetized. Bell reasoned thus: when words are spoken in front of the tube T the membrane will be set in vibration and with it the armature A, and the vibration of the armature in front of the electromagnet will induce variations in the line current; their magnitude will be proportional to the amplitude, and their frequency to the frequency of the vibrations of the armature; in fact, the difference between the actual and the average current in the circuit will be at each instant proportional to the rate of motion of the armature. It follows from this that the armature and membrane of the distant instrument should have induced in them a motion precisely similar to that of the membrane of the transmitter. This telephone was made in June, 1875, but was put aside after trial as unsatisfactory on account of the feebleness of the sounds it produced; since then, however, a successful telephone has been made on precisely the same plan as that here indicated.

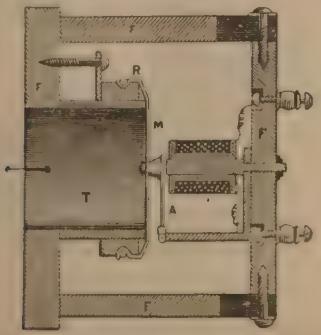

FIG. 2.—Bell's first telephone; one-fifth full size.

Bell's second telephone.

The next form tried is shown in Fig. 3. It is very similar except in constructive details to the first; the hinged armature, however, is omitted, its place being taken by a small iron disk A fixed to the centre of the diaphragm D. The electromagnet H is, as before, placed so as to have the centre of the soft iron core C opposite to the centre of the disk, and the theory according to which it was expected to act is the same. The results obtained with this instrument were much more satisfactory; indeed it was with one precisely like that shown in the figure that the remarkable results of the Philadelphia Exhibition in 1876 were obtained. A perspective and a sectional view of the receiving instrument used along with that shown in Fig. 3 are illustrated in Figs. 4 and 5. It consisted of an iron cylindrical box B, through the axis of which a rod of soft iron C was passed to form the core of an electromagnet, having the magnetizing helix H wound on the upper half of its length. Across the top of the box a thin disk D of soft iron was fixed, the core C being just clear of the disk when the strongest current is flowing through the helix. In the perspective view the disk is removed, showing the end of the core. These instruments are interesting, not only because they may be considered the first really successful speaking telephones, but because they are of the same form as those brought to Great Britain in 1876 by Sir W. Thomson, and exhibited before the British Association at Glasgow in that year.

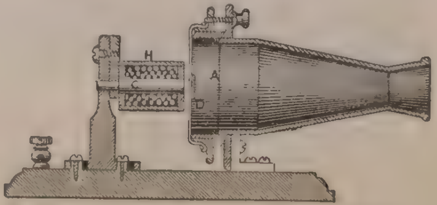

FIG. 3.—Bell's second telephone; one-fifth full size.

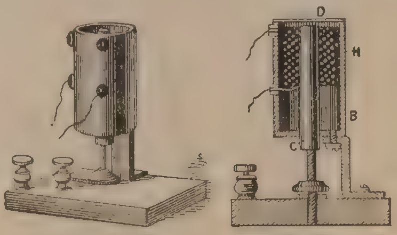

FIG. 4. FIG. 5.

FIGS. 4, 5.—Bell's iron box receiver (1876).
FIG. 4, perspective view; FIG. 5, sectional view.

Fig. 6 shows one of the earliest forms brought into commercial use. On each pole of a somewhat large horse-shoe permanent magnet M a short coil E with a soft iron core was fixed. This is one of the early forms of permanent magnet telephones, of which there were at that time several, including a hand telephone very similar to that shown in Fig. 7. In another form, introduced about the end of 1877, the small magnetizing coils and soft iron cores were fixed

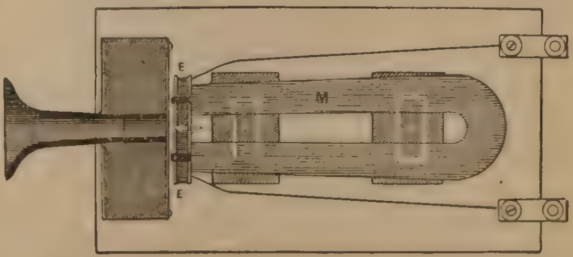

FIG. 6.—Bell's multiple pole telephone (1877); one-fifth full size.

on the side and opposite the poles of the horse-shoe magnet, and the diaphragm was placed with its plane parallel to that of the magnet. The diaphragm in these telephones was of thin sheet iron and a little over 4 inches in diameter.

Bell's hand telephone.

The form of telephone now almost universally in use is shown in Fig. 7. It was introduced in December, 1877, and consists of a compound permanent magnet M, fitted into the centre of a tube of vulcanite or "hard rubber" and carrying at one end a short electromagnet, the coil of which through its terminals *t*, *t* is included in the circuit when the instrument is in use. In front of the electromagnet, with its plane normal to the axis of the magnet, is fixed a thin soft iron disk about 1¾ inches in diameter, which has its cover cut to a convenient shape to form a mouthpiece. This telephone acts well either as a transmitter or as a receiver; but for the former purpose it is now seldom used on account of the great advances which have been made in "microphone" transmitters.

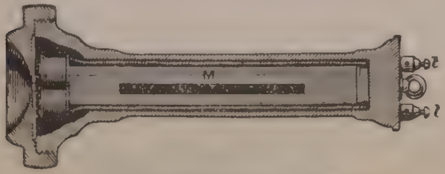

Fig. 7.—Bell's hand telephone, present form.

Bell's liquid transmitter.

It has been stated that Bell and Elisha Gray almost simultaneously suggested the use of a column of liquid to vary the resistance in the circuit. The form of instrument proposed by the former and said to have been exhibited at the Philadelphia exhibition is shown in Fig. 8. It consists of a speaking tube or mouthpiece M, across the lower end of which a membrane D is stretched. To the centre of the membrane a light rod R, made of metal or of carbon, is fixed with its length at right angles to the plane of the membrane. Under the lower end of R a small metallic vessel C is supported on a threaded rod, working in a nut fixed to the sole F, so that its height may be readily adjusted. Suppose C to be filled with water or any other conducting liquid, and the rod R to be of metal. C is raised until the liquid just touches the point of the rod, when advantage is taken of the change of contact resistance with the greater or less immersion of R during the vibration of D. Good results were obtained with mercury as the liquid and with a rod of carbon.

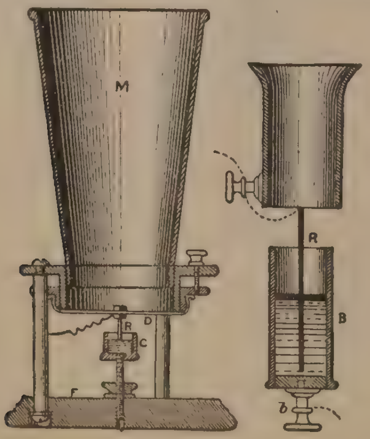

Fig. 8. Fig. 9.

Fig. 8.—Bell's liquid transmitter.
Fig. 9.—Elisha Gray's liquid transmitter.

E. Gray's liquid transmitter.

The arrangement proposed by Elisha Gray is almost identical in form with Bell's. The only difference seems to be that Gray intended the rod R (Fig. 9) to reach near to the bottom of the vessel B or to the end of another rod, a prolongation of *b*, projecting up from the bottom. The variation of the current was produced by the variation of the distance between the ends of the rod caused by the vibrations of the diaphragm. This plan was not tried until after the success of Bell's experiments was known, and when it was tried the results did not prove encouraging. Indeed the variations of the resistance which can be produced in this way must be excessively small, unless the liquid has a very high specific resistance, the distance between the ends is very small, and the sides of the rods are prevented by an insulated covering from interfering with the results. Neither of these transmitters has any great merit as such, but they show that both Bell and Gray clearly recognized the principle on which successful transmission of the different forms of sound, including speech, could be accomplished.

Edison's microphone transmitter.

The first successful microphone transmitter was Edison's. An early form of it (Fig. 10) somewhat resembles Bell's hand telephone in external form. A cell of insulating material has at its bottom a flat-headed platinum screw G; on the top of G is a layer of carbon powder C, on the top of that a thin platinum disk D, and above that, forming the cover of the cell, a disk of ivory B, held in position by a ring E. Resting on the centre of this disk is a small piece of rubber tubing, which is lightly pressed by the diaphragm A, and this, as in the hand telephone, is held in position by the mouthpiece M. The varying pressure on A, when a sound is produced near it, causes corresponding variations in the pressure on the carbon powder, and this produces similar variations in its electrical resistance. Thus, when the instrument is included in an electric circuit through which a current is flowing, undulations in the pressure on the diaphragm produce corresponding undulations in the current.

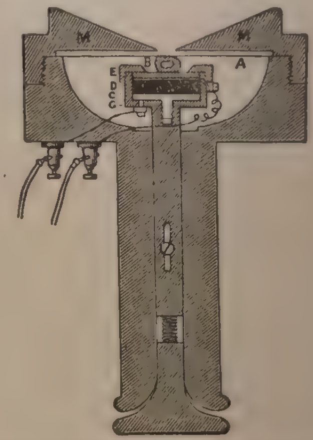

Fig. 10.—Edison's microphone transmitter.

Hughes's microphone.

Perhaps the best known forms of the microphone are those introduced by Prof. Hughes. One of the commonest is shown in Fig. 11. It consists of two rectangular pieces of wood, B and D, fixed together with their planes at right angles to each other. D forms the base, and to B two small blocks of carbon C, C are attached. Between these a light rod A of the same material is supported on small cups formed in C, C. To the blocks two electrodes *e*, *e* are connected for the purpose of inserting the instrument in an electric circuit. The material which Hughes found most suitable for the carbon blocks and rod was wood charcoal metallized by heating it to redness and plunging it while hot into mercury. If this microphone is joined in circuit with a telephone and a small battery, say one or two small Daniell cells, the vibration produced by a fly walking on the base D can be distinctly heard in the telephone. The same appa-

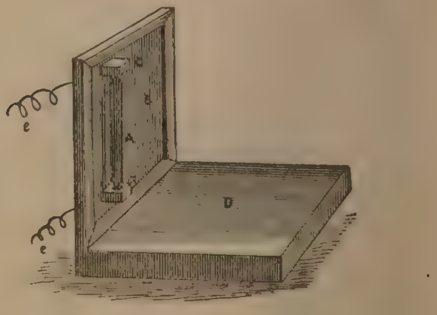

Fig. 11.—Hughes's microphone.

ratus will also act as a microphone transmitter, but the sounds are apt to be harsh. A better form for this purpose is shown in Fig. 12. In this a light pencil of carbon M is pivoted at *h* and has one end resting on two blocks of carbon *c*, *c*, the lower one being fixed to the base. The pressure of M on the carbon block is regulated by a spring *s*. This arrangement is enclosed in a box of thin wood, against which the sound is directed. It is capable of acting well as a transmitter, and especially in a modified form used by Hughes as a microphone receiver. The lower block *c* is then attached to the centre of a vertical diaphragm and against it the sounds are directed.

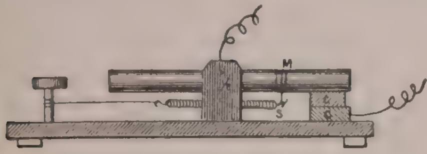

FIG. 12.—Microphone transmitter.

Blake transmitter.

The Blake transmitter, which is perhaps most widely used of all, is a simple modification of the Hughes instrument last described. It consists (Fig. 13) of a frame F, to which is attached a diaphragm D of thin sheet iron; in front of this is a cover M, M provided with a suitable cavity for directing the sound-waves against the diaphragm. The microphonic arrangement consists of a spring S, about the hundredth of an inch thick and the eighth of an inch broad, fixed at one end to a lever L, and carrying at its free extremity a brass block W. In one side of W a small disk C of gas carbon is inserted, resting on the hemispherical end of a small platinum pin K, about the twentieth of an inch in diameter, held in position by a thin spring A. The pressure of the carbon on the platinum point can be adjusted by the screw N, which turns the lever about the flexible joint G. The electrical connections of the instrument as arranged for actual use are also illustrated in the figure. The current circuit goes through S, W, C, K, A, and the primary circuit of the induction coil I to the battery B, and thence to S again. This forms a local circuit at the transmitting station. The line of circuit passes through the secondary of the induction coil I to the line, from that to the telephone T at the receiving station, and then either to earth or back to the induction coil by a return line of wire.

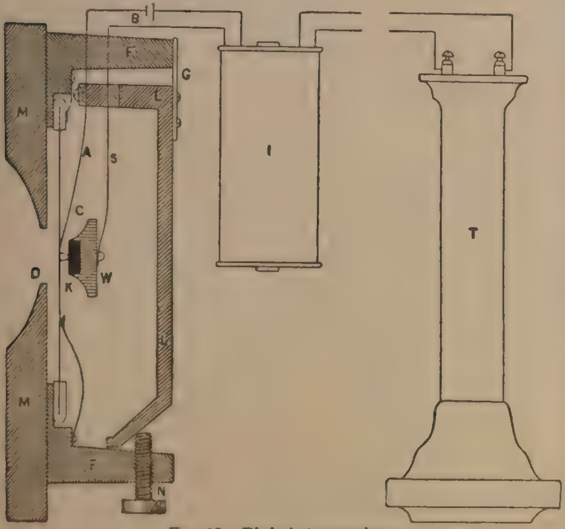

FIG. 13.—Blake's transmitter.

Telephonic Circuits.

Telephone wires.

The lines used for telephone purposes are, generally speaking, so far as erection, mode of insulation, and so on are concerned, much the same as those used for ordinary telegraphs. In towns where a very large number of wires radiate from one centre or exchange, as it is called, where thick wires are unsightly, and where it is often necessary to provide for long spans, a comparatively thin wire of strong material is employed. For this reason various bronzes, such as silicon, aluminium, etc., have come to be extensively used for making wires for telephone lines. They are made from about the twentieth to the thirtieth of an inch in diameter, and are found to wear well in the somewhat mixed atmosphere of a town; and owing to their lightness and considerable tensile strength it is comparatively easy to erect them and keep them in order. The main objection to them is the high electrical resistance they oppose to the current. The lines on a town exchange system are not, however, as a rule, so long as to make this objection of great importance. But long lines, such as those extending between towns some miles apart, should be made of pure copper wire hard drawn. It has lately been found possible to draw copper so hard as to be almost equal to bronze in strength, and yet to retain about three times the electric conductivity of that substance. Copper and bronze wires possess great advantages for telephonic purposes over the iron wires employed in telegraph lines, in that they offer a much lower effective resistance to the rapidly undulating and intermittent currents produced by telephonic transmitters. The electric resistance opposed by a wire to the passage of such a current is always greater than that opposed to a steady current, and this difference is much more marked when the wire is of magnetic material like iron. This increased resistance rises in proportion to the rapidity of the undulations of the current; consequently high notes are more resisted than low notes. Besides this variable resistance, telephony has to contend with "self-induction" (see ELECTRICITY, vol. viii. pp. 74–76 *sq.*) of the current on itself, and this is by no means unimportant, especially on long circuits.[1] The marked difference between iron and copper for long circuits is plainly shown by the fact that Rysselberg and others have spoken clearly to a distance of over 1000 miles through a copper wire insulated on poles, whereas Preece could not work a similar line of iron wire between London and Manchester.

Capacity.

The electrostatic capacity of the line (see TELEGRAPH, p. 123 above) is also diminished by the use of thin wires of highly conducting material. They should all if possible be erected on poles at a considerable height above the earth. It is not practicable to work an ordinary underground line through more than 20 miles, and cable telephony through distances of over 100 miles may in the present state of science be put down as an impossibility.

Induction.

Another element of great importance in connection with telephone lines, which in most cases does not require to be attended to in ordinary telegraph circuits, is the induction from one line to another (see ELECTRICITY, vol. viii. p. 71 *sq.*). When two lines having, as in ordinary telegraphy, an earth connection at each end run for any great distance, say a mile or more, parallel to each other on the same supports, a conversation which is being carried on through one of them can be overheard by means of the telephones on the other. This is due to the fact that, when a current is suddenly set up in one closed circuit, it induces an instantaneous current in any other closed circuit which is near to it. This induced current not only destroys the privacy of the circuit in question but also lowers its efficiency. The mischief is even greater when telegraph and telephone lines run along the same route supported on the same poles, because the strong intermittent currents sent through telegraph wires and the irregular manner in which the intermittences follow each other, induce a series of such powerful secondary currents in the telephone lines that the noise heard in the telephone is often sufficient, when the line is a mile or two long, to drown all speech.

Methods for overcoming induction.

In the case of parallel telephone lines the best, if not the only, cure is to use return wires, and arrange them so that the currents induced in the outgoing wire shall be neutralized by the corresponding current induced in the incoming wire. For mixed telegraph and telephone circuits various methods have been proposed; but the most generally approved plan is to have return wires. For circuits worked wholly on the return principle the main thing to be attended to is the symmetrical arrangement of the wires, so that the outgoing and incoming wires may be subjected to the same influence. This is nearly provided for by running them in such a way that they may all be supposed to lie on the surface of a cylinder in lines parallel to its axis, the two wires at the opposite ends of a diameter being always used for the same circuit. When more than four wires form the group complete compensation is not obtained in this way, because the current is always stronger near the transmitting end of the line than near the receiving end, on account of the very sensible effect of the capacity and the leakage of the line. It is therefore best to arrange the wires in groups of four—that is, in pairs of circuits—and run them so as to form spiral lines round an axial line equidistant from each of the four wires. Any pair of wires forming a circuit which runs parallel to other wires can be arranged so as to be very nearly free from induction by interchanging their position relatively to the other wires at short distances along the line. Care must, however, be taken, when more than one group of four or when more than one pair are run, that the compensation produced by the twisted arrangement of one set, or of the interchanges of the wires in the different pairs, is not spoiled by the twisting or interchanging of another set or pair. Telephone lines running parallel to telegraph lines should be formed into one or more groups, each being run on the twist plan so as to eliminate as completely as possible the effect of the telegraph signals; the small residual effect of the telephone signals is of comparatively little importance in such a case. A twisted cable of telephone wire may, when each circuit is formed by diametrically opposite wires, be placed in the same tube with similar cables employed for telegraph purposes. The central wire of the cable may be used either as a telegraph line or as a telephone line having an earth return. Another method is to use powerful telephone transmitters and insensitive receivers; that is to say, make the telephone currents so powerful that the telegraphic induced currents will be small in comparison, and use receivers so insensitive as to suit such currents. One of the main obstacles in the way of this method at present is the difficulty of getting strong telephonic currents, for even the best transmitters are not yet sufficiently powerful, and there is, besides, a decided tendency towards a loss of quality in the sound when the transmitter is made powerful. A third method is to render the telegraphic current comparatively harmless by taking away the suddenness of the intermittences. This is quite possible because the number of currents sent per second, even on fast working circuits, is not such as to produce a high musical note. If, then, the currents be made in some way to rise slowly to their full strength and fall again slowly to zero, the diaphragm of the receiving instrument, instead of showing the sudden rise and sudden fall as at present, would move so slowly backwards and forwards that the ear would not be disturbed by the sound. Perhaps the simplest way to accomplish this is to place an electromagnet in the circuit of the telegraph line at the sending station, for the self-induction of the magnet-coil prevents the current assuming its strength suddenly. But on telegraph circuits where speed is of great importance this method cannot be followed owing to the retardation of the telegraph signals and the consequent loss of speed thereby occasioned.

Rysselberg's system.

An ingenious application of the method of compensation just indicated has been made by Rysselberg, who has used not only wires carried on the same poles as the telegraph but even the telegraph lines themselves for telephone purposes. The arrangement of his system is shown in Fig. 14, where L and L_1 represent two telegraph lines. Between these, at each end, are inserted two condensers C_1, C_2 and a telephone T, together with transmitters, etc., so that, supposing the telegraph instruments removed, the two wires would be an ordinary telephone circuit worked through condensers. The telegraph apparatus consists of an ordinary receiver R, sending battery B, and key K, together with a condenser C, inserted between the earth and the line terminal of the key, and two electromagnetic inductors E, E′. When the key is depressed the current is retarded by the electromagnet E and the condenser C, which has to be charged, giving in fact additional electrostatic capacity at the sending end of the line. The current is still further retarded by the electromagnet E′; hence the condenser C_1 becomes charged so gradually that very little disturbance is noticeable in the telephone T. The condensers C_1, C_2 prevent leakage from one line to the other, but have sufficient capacity to allow the telephone to act as if it were in a metallic circuit.

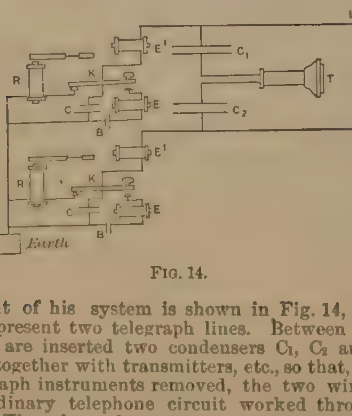

Fig. 14.

The Working of Telephone Circuits.

Early methods.

The method first employed for working a telephone line was extremely simple. A single line of wire, like an ordinary telegraph line, had a Bell telephone included in it at each end and the ends were put to earth. Words spoken to the telephone at one end could be heard by holding the telephone to the ear at the other. To obviate the inconvenience of placing the telephone to the mouth and the ear alternately, two telephones were commonly used at each end, joined either parallel to each other or in series. The contrivance most generally adopted for calling attention is the call bell, rung either by a small magneto-electric machine or by a battery. The telephone was switched out of circuit when not in use and the bell put in its place, an ordinary key being used for putting the battery in circuit to make the signal. This arrangement is still employed, a hook being attached to the switch lever so that the mere hanging up of the telephone puts the bell in circuit. In some cases, when the bell is rung by a magneto machine, the coil of the machine is automatically cut out of circuit when it is not in action, but the turning of the handle moves a centrifugal arrangement by which it is thrown in.

Working with microphone.

At first it was usual to employ the same instrument both as transmitter and as receiver, and to join it in the direct circuit. But it was soon found that the microphone transmitter could only be used to advantage in this way when the total resistance of the circuit, exclusive of the microphone, was small compared with the resistance of the microphone,—that is, on very short lines worked with low resistance telephones. The transmitter on long and high resistance lines worked better by joining indirectly in a local circuit, in the manner shown in Fig. 13, the microphone, a battery, and the primary of an induction coil, and putting the line in circuit with the secondary of the induction coil, which acted as the transmitter. The resistance of the microphone can thus be made a large fraction of the total resistance of the circuit in which it is placed; hence, by using considerable currents, small variations in its resistance can be made to induce somewhat powerful currents in the line wire. The requisite energy is derived from the battery. If there are other resistances in the circuit it is, in some cases, better to join it as a shunt to the primary circuit of the induction coil. It may even prove advantageous to insert resistances in the circuit, increase the battery power, and join the microphone as here indicated, because in this way powerful currents can be obtained in the line without the harshness which is apt to be produced by the variations of a strong current passing through the microphone.

Translation.

Translation from one line to another, or from one section to another of the same line, is effected by putting the primary of an induction coil in the place of the receiving telephone, the secondary being in circuit with the second line or section. This plan is useful where the same message is to be sent to different places at once (distributed), and is sometimes used for translating from a double wire to a single wire system. Probably a better plan is to work a microphone by the membrane of the receiving telephone, and re-transmit the message, taking new energy from a second battery.[1] When the induction coil arrangement is used for translating from a double to a single wire circuit, or *vice versa*, it is necessary to make the induction coil suit the circuits, so that either coil may be used as primary, according to the end from which the message is sent. Everything else being similar, the resistances of the coils should be in nearly the same ratio as the resistances of the lines in which they are placed.

Exchanges.

In a large town it is neither practicable nor desirable to connect each subscriber directly with all the other subscribers, hence a system of "exchanges" has been adopted. An exchange is a central station to which wires are brought from the different subscribers, any two of whom can be put in telephonic communication with each other when the proper pairs of wires are joined together in the exchange. The arrangement is illustrated in Fig. 15, where C represents an exchange from which wires radiate to the points *a*, *b*, *c*, *d*, . . . Suppose *a* wishes to speak to *d*; he communicates his wish to an attendant at C, who first calls *d*, and then connects 6 to 1, making the circuit continuous from *a* to *d*. The arrangements at the exchange for facilitating connections vary considerably, but are similar in principle to the switch boards used in telegraphy. Each of the wires is first brought to an indicator and then to a set of terminals arranged in an orderly manner on a board, the number of the terminal for any one wire being the same as the number under the shutter of the indicator in that wire circuit. In many cases the terminals take the form of spring clips, which connect the line to earth, and under which a thin piece of metal, covered with insulating material on one side and called a "jack," can be readily inserted for connecting that circuit with any other. A piece of flexible wire cord, carrying a jack at each end, forms a ready and common medium of connection; but in many cases the switch board is arranged with cross strips of metal so that by inserting a jack into the terminals of the two wires they can be both connected to the same strip of metal and therefore together. In large exchanges one switch board of moderate size is not sufficient, and so a number are fitted, being connected together by several conductors, in order that no interruption may ensue in consequence of these being all occupied. A line on one board is connected with one on another board by joining the terminal of the first to one of the conductors connecting the two boards by a jack-cord, and then by another jack-cord connecting that conductor to the terminal of the other line. Thus different switch boards may be looked upon as separate exchanges, connected together by a number of trunk wires after the manner described below.

---

[1] See Thomson and Houston, *Tel. Journ.*, 15th August, 1878.

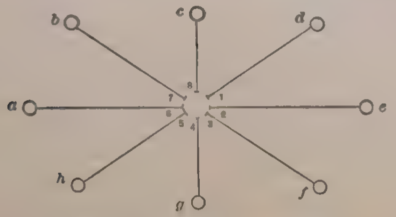

FIG. 15.—Telephone exchange.

In a large system it is much more convenient and economical to have exchanges in the various districts, and connect these with a central exchange by a sufficient number of trunk lines. A subscriber in one district wishing to speak to a subscriber in another calls the exchange in his own district and is put in communication by the attendant stationed there with the central exchange. The attendant at the central exchange puts the subscriber in communication with the district he requires, and the attendant there calls the other subscriber and joins the two subscribers' lines together. In some cases neighboring district exchanges have, besides a common means of communication through the central exchange, an independent connection. These arrangements are diagrammatically illustrated in Fig. 16, where 1, 2, 3, 4, 5, 6 represent district exchanges and C the central exchange; districts 3 and 4 and 4 and 5 are supposed to have independent connections.

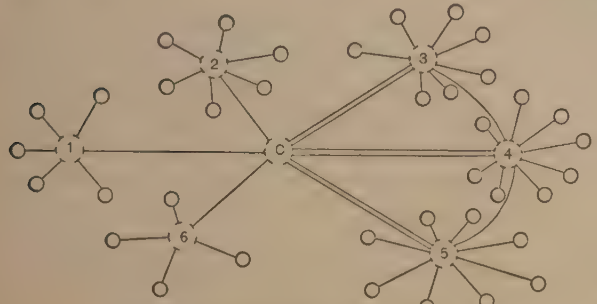

FIG. 16.—Telephone district exchanges.

Sinclair's automatic exchange.

An arrangement was proposed about two years ago by Mr. D. Sinclair of the Glasgow telephone exchange for allowing small district exchanges to be worked by the attendants at the central exchange.[1] The two exchanges are connected by a trunk line and from the district exchange wires are led to the different subscribers. These wires are in the normal state of matters connected with contact plates, over which an arm joined to the trunk wire can be made to travel. Suppose the central exchange wishes to speak to any one of the subscribers, the arm is made to travel round, by currents sent from the exchange through an electromagnetic step by step arrangement, until it comes in contact with the proper plate, after which the subscriber is called in the ordinary way. When one subscriber belonging to the district exchange wishes to speak to another in the same district, he rings the bell in the ordinary way, and this operation disconnects all other subscribers and puts him in connection through the trunk line with the central exchange. The attendant there ascertains to whom it is that he wishes to speak, and by moving round the contact arm puts the two subscribers' lines in contact.

Indicator or annunciator.

The indicator, or annunciator as it is sometimes called, is shown in Fig. 17. It consists of an electromagnet, M, which on a current being sent through it pulls down the armature *a*, relieves the catch *c*, and allows the shutter *d* to fall down, exposing a plate *p*, on the front of which the number of the subscriber is printed. When the exchange is called, the shutter *d* is dropped, the attendant connects the line leading to the exchange table with the terminal corresponding to the indicator, and finds who is wanted; then he calls that subscriber, makes the through connection, and puts up the shutter. When the subscribers have finished, both call the exchange, or, as it is commonly put, "ring off;" this drops both shutters and serves as the signal that they have finished speaking.

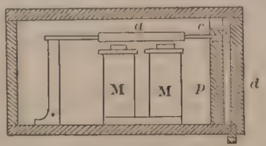

FIG. 17.—Indicator or annunciator.

Radiophone.

The principle of transmitting sound by the radiophone will be understood from Fig. 18. M represents a mirror, from which a beam of light is reflected through the lens *l* to a second mirror *m*, and *m* forms a diaphragm against the back of which the sound vibrations sent through the tube *t* are made to impinge. The beam of light, after being reflected from *m*, passes through the lower lens *l*, and thence as a nearly parallel beam to the parabolic reflector R. A photophonic receiver P, supposed in this case to be a spiral of selenium wire wound on the surface of a cylinder, is placed at the focus of the reflector so that the beam of light from *m* is concentrated on it. In circuit with the receiver P a battery B and a telephone T are included, and through the circuit a feeble electric current flows continuously. The photophonic receiver should be placed so as to receive as little light as possible from any other source than the mirror *m*. Words spoken through the tube *t* make the mirror *m* vibrate, so that the beam of light reflected from it becomes more or less spread. The lens *l* is then unable to bring the beam into parallelism, and the intensity of the reflections from R to P is varied, therefore also the current through the coil of the telephone, which in consequence gives out a sound. The amount of spreading of the beam being proportional to the intensity of the vibrations of *m*, and this again proportional to the intensity of the sounds, the sounds heard in the telephone are similar to those produced at the end of *t*. Theoretically the receiver may be at any distance from the transmitter, but considerable difficulty arises if the distance is great.

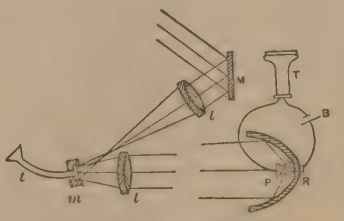

FIG. 18.—Bell's radiophone.

---

[1] See *Proc. Phil. Soc. of Glasgow*, vol. xvii. p. 39.

Phonograph.

One of the simplest forms of the phonograph is shown in Fig. 19. It consists of a rigid spindle S screwed for about one-third of its length, and fitted to work smoothly but tightly in the frame *f*, *f*, which is securely attached to a sole plate P. On the spindle a drum D is fixed, the axis of which coincides accurately with that of the spindle. On the surface of the drum a screw is cut of precisely the same pitch as that on the spindle. A fly-wheel W is fixed to one end of the spindle, and is provided with a handle H, by which the spindle and drum can be conveniently turned. One of the bearings has either a screw thread cut along it, or is fitted with one or more studs which work easily, but without shake, in the screw thread. When the spindle is turned, it receives a transverse motion, and a point fixed relatively to the sole plate P and touching the drum traces out a spiral on its surface, exactly coinciding with the screw thread cut on it. A mouthpiece M, like that of a telephone-transmitter, provided with a diaphragm of parchment or similar substance, is mounted on a lever, which is pivoted at *h* and provided with a set screw *b*. A blunt needle point is either fixed to the centre of the diaphragm or carried by a light spring in such a way as to press on the centre of the diaphragm with the needle point projecting outwards. To use the instrument, the drum D is covered with a sheet of somewhat stiff tinfoil, and the mouthpiece is adjusted as shown in the figure, with the needle point over the hollow part of the tinfoil, and fixed by the set screw to make a slight indentation in it. The drum is then turned and words spoken in a somewhat loud and clear tone in front of the mouthpiece. The vibrations of the diaphragm cause the needle point to make indentations more or less deep, according to the intensity of the sound, in the surface of the tinfoil. If the mouthpiece is then raised, the drum turned back to its original position, the mouthpiece lowered so that the point rests on the groove which it previously made, and the drum again turned, the diaphragm, acted on by the needle point passing over the indentation, will give out the same words which were spoken to it. (T. GR.)

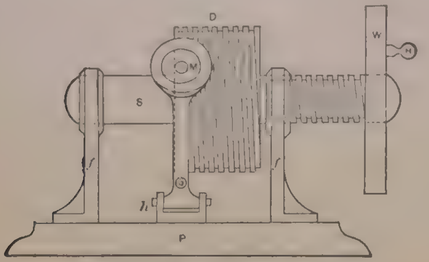

FIG. 19.—Edison's phonograph.

TELESCOPE.

THE telescope is an optical instrument employed to view or discover distant objects.[1] The fundamental optical principles involved in its construction have already been dealt with in the articles LIGHT and OPTICS, and these should be first perused by the reader.

HISTORY.

Roger Bacon.

The credit of the discovery of the telescope has been a fruitful subject of discussion. Thus, because Democritus announced that the milky way is composed of vast multitudes of stars, it has been maintained that he could only have been led to form such an opinion from actual examination of the heavens with a telescope. Other passages from the Greek and Latin authors have similarly been cited to prove that the telescope was known to the ancients. But, as has been remarked by Dr. Robert Grant (*History of Physical Astronomy*, p. 515), we are no more warranted in drawing so important a conclusion from casual remarks, however sagacious, than we should be justified in stating that Seneca was in possession of the discoveries of Newton because he predicted that comets would one day be found to revolve in periodic orbits. Molyneux, in his *Dioptrica Nova*, p. 256, declares his opinion that Roger Bacon (who died *c.* 1294) "did perfectly well understand all kinds of optic glasses, and knew likewise the method of combining them so as to compose some such instrument as our telescope." He cites a passage from Bacon's *Opus Majus*, p. 377 of Jebb's edition, 1733, translated as follows:

> "Greater things than these may be performed by refracted vision. For it is easy to understand by the canons above mentioned that the greatest objects may appear exceedingly small, and the contrary, also that the most remote objects may appear just at hand, and the converse; for we can give such figures to transparent bodies, and dispose them in such order with respect to the eye and the objects, that the rays shall be refracted and bent towards any place we please, so that we shall see the object near at hand or at any distance under any angle we please. And thus from an incredible distance we may read the smallest letters, and may number the smallest particles of dust and sand, by reason of the greatness of the angle under which we see them. . . . Thus also the sun, moon, and stars may be made to descend hither in appearance, and to be visible over the heads of our enemies, and many things of the like sort, which persons unacquainted with such things would refuse to believe."

Molyneux also cites from Bacon's *Epistola ad Parisiensem*, "Of the Secrets of Art and Nature," chap. 5:

> "Glasses or diaphanous bodies may be so formed that the most remote objects may appear just at hand, and the contrary, so that we may read the smallest letters at an incredible distance, and may number things, though never so small, and may make the stars also appear as near as we please."

These passages certainly prove that Bacon had very nearly, if not perfectly, arrived at theoretical proof of the possibility of constructing a telescope and a microscope; but his writings give no account of the trial of an actual telescope, nor any detailed results of the application of a telescope to an examination of the heavens. It has been pointed out by Dr. Smith, in his *Complete System of Optics*, that Bacon imagines some effects of telescopes which cannot be performed by them, and his conclusion is that Bacon never actually looked through a telescope.

Della Porta.

Giambattista della Porta, in his *Magia Naturalis*, printed in 1558, makes the following remarkable statement:

> "If you do but know how to join the two (viz., the concave and the convex glasses) rightly together, you will see both remote and near objects larger than they otherwise appear, and withal very distinct."

Wolfius infers from this passage that its author was the first actual constructor of a telescope, and it appears not improbable that by happy accident Porta really did make some primitive form of telescope which excited the wonder of his friends. Here, however, his interest in the matter appears to have ceased, and he was unable either to appreciate the importance of his discovery or to describe the means by which the object was attained. Kepler, who examined Porta's account of his concave and convex lenses by desire of his patron the emperor Rudolph, declared that it was perfectly unintelligible. Poggendorff (*Gesch. der Physik*, p. 134) throws considerable doubt on the originality of Porta's statement.

---

[1] In recent years the term "photographic telescope" has been applied to instruments employed to record the appearance of celestial objects by photography.

Leonard Digges.

Thomas Digges, in his *Stratioticus*, p. 359, published in 1579, states that his father, Leonard Digges.

> "Among other curious practices had a method of discovering by perspective glasses set at due angles all objects pretty far distant that the sun shone upon, which lay in the country round about."

And that this was by the help of a manuscript book of Roger Bacon, of Oxford, who he conceived was the only man besides his father who knew it. There is also the following passage in the *Pantometria* (bk. i. chap. 21) of Leonard Digges[1] (originally published by his son Thomas in 1571, and again in 1591):

> "Marvellous are the conclusions that may be performed by glasses concave and convex, of circular and parabolic forms, using for multiplication of beams sometime the aid of glasses transparent, which, by fraction, should unite or dissipate the images or figures presented by the reflection of other."

He then describes the effects of magnification from a combination of lenses or mirrors, adding:

> "But of these conclusions I minde not here to intreate, having at large in a volume[2] by itselfe opened the miraculous effects of perspective glasses."

It is impossible to discredit the significance of these quotations, for the works in which they occur were published more than twenty years before the original date claimed for the discovery of the telescope in Holland.

That Roger Bacon had tolerably clear ideas as to the practical possibility of constructing telescopes, and that Leonard Digges had access to some unpublished MSS. of Bacon, and by their aid constructed some form of telescope, seem to be obvious inferences from the preceding evidence. But it is quite certain that previous to 1600 the telescope was unknown, except possibly to individuals who failed to see its practical importance, and who confined its use to "curious practices" or to demonstrations of "natural magic." The practical discovery of the instrument was certainly made in Holland about 1608, but the credit of the original invention has been claimed on behalf of three individuals, Hans Lippershey and Zacharias Jansen, spectacle-makers, in Middelburg, and James Metius, of Alkmaar (brother of Adrian Metius, the mathematician).

The Dutch telescope of 1608.

Descartes, in his treatise on *Dioptrics* (1637), attributes the discovery to Metius "about thirty years ago," whilst Schyrælus de Rheita, a Capuchin friar, in his *Oculus Enoch et Eliæ* (Antwerp, 1645), gives the credit to Lippershey about 1609. Peter Borel, physician to the king of France, published at The Hague, in 1655, a work *De Vero Telescopii Inventore*. He was assisted in its preparation by William Borel, Dutch envoy at the court of France, and the latter declares, as the result of patient investigation, that Jansen and his father were the real inventors of the telescope in 1610, and that Lippershey only made a telescope after hints accidentally communicated to him of the details of Jansen's invention. But the most trustworthy information on the subject is to be got from the researches of Van Swinden.[3] Briefly summarized, this evidence is as follows. In the library of the university of Leyden, amongst the MSS. of Huygens there is an original copy of a document (dated 17th October, 1608) addressed to the states-general by Jacob Andrianzoon (the same individual who is called James Metius by Descartes), petitioning for the exclusive right of selling an instrument of his invention by which distant objects appear larger and more distinct. He states that he had discovered the instrument by accident when engaged in making experiments, and had so far perfected it that distant objects were made as visible and distinct by his instrument as could be done with the one which had been lately offered to the states by a citizen and spectacle-maker of Middelburg. Among the Acts of the states-general preserved in the Government archives at The Hague, Van Swinden found that on 2d October, 1608 the assembly of the states took into consideration the petition of Hans Lippershey, spectacle-maker, a native of Wesel and an inhabitant of Middelburg, inventor of an instrument for seeing at a distance. On 4th October a committee was appointed to test the instrument, and on the 6th of the same month the assembly agreed to give Lippershey 900 florins for his instrument. Further, on the 15th December of the same year they examined an instrument invented by Lippershey at their request to see with both eyes, and gave him orders to execute two similar instruments at 900 florins[4] each; but, as many other persons had knowledge of this new invention to see at a distance, they did not deem it expedient to grant him an exclusive privilege to sell such instruments. The dates of these documents dispose effectually of Borel's statement that Lippershey borrowed the ideas of Jansen in 1610. They also prove that, whilst Metius was in possession of a telescope, with which he may have experimented, about the time when Lippershey presented his application for patent rights, yet he makes no pretension that Lippershey borrowed the invention from him. The conclusion is that Lippershey was the first person who independently invented the telescope, and at the same time made the instrument known to the world. The common story is that Lippershey, happening one day, whilst holding a spectacle lens in either hand, to direct them towards the steeple of a neighboring church, was astonished, on looking through the nearer lens, to find that the weathercock appeared nearer and more distinct. He fitted the lenses in a tube, in order to adjust and preserve their relative distances, and thus constructed his first telescope. But doubt may be thrown on this traditional account owing to the further statement that the image of the weathercock so viewed was seen turned upside down. All the original Dutch telescopes were composed of a convex and a concave lens, and telescopes so constructed do not invert. The inverting telescope, composed of two convex lenses, was a later invention; still it is not impossible that the original experiment was made with two convex lenses.

Jansen.

Metius.

Lippershey.

Telescopes seem to have been made in Holland in considerable numbers soon after the date of their invention, and rapidly found their way over Europe. Sirturus, in his *De Telescopio* (1618), states that "a Frenchman proceeded to Milan in the month of May, 1609, and offered a telescope for sale to Count di Fuentes;" and Lorenzi Pigorna writes,[5] under date 31st August, 1609, that "Galileo had been appointed lecturer at Padua for life on account of a perspective like the one which was sent from Flanders to Cardinal Borghese." Simon Marius, the German astronomer, appears to have made astronomical observations in 1609 with a telescope which he procured from Holland, and Professor Rigaud, of Oxford, found from the MSS. of Harriot, the mathematician, that he had been making astronomical observations with a Dutch telescope as early as July, 1609.

Galileo.

Galileo, in his *Nuncius Sidereus*, states that, happening to be in Venice about the month of May, 1609, he heard that a Belgian had invented a perspective instrument by means of which distant objects appeared nearer and larger, and that he discovered its construction by considering the effects of refraction. In his *Saggiatore* Galileo states that he solved the problem of the construction of a telescope the first night after his return to Padua from Venice, and made his first telescope next day by fitting a convex lens in one extremity of a leaden tube and a concave lens in the other one. A few days afterwards, having succeeded in making a better telescope than the first, he took it to Venice, where he communicated the details of his invention to the public, and presented the instrument itself to the doge Leonardo Donato, sitting in full council. The senate, in return, settled him for life in his lectureship at Padua and doubled his salary, which was previously 500 florins, and which then became treble that which any of his predecessors had enjoyed. Galileo may thus claim to have invented the telescope independently, but not till he had heard that others had done so. In fact the time was ripe; and, as often happens in similar circumstances, only a hint was necessary to complete the latent chain of thought. Galileo devoted all his time to improving and perfecting the telescope. Knowing the theory of his instrument, and possessed of much practical skill, coupled with unwearied patience, he conquered the difficulties of grinding and polishing the lenses, and soon succeeded in producing telescopes of greatly increased power. His first telescope magnified three diameters; but he soon made instruments which magnified eight diameters, and finally one that magnified thirty-three diameters.[1] With this last instrument he discovered in 1610 the satellites of Jupiter, and soon afterwards the spots on the sun, the phases of Venus, and the hills and valleys on the moon. He demonstrated the rotation of the satellites of Jupiter round the planet, and gave rough predictions of their configurations, proved the rotation of the sun on its axis, established the general truth of the Copernican system as compared with that of Ptolemy, and fairly routed the fanciful dogmas of the philosophers. These brilliant achievements, together with the immense improvement of the instrument under the hands of Galileo, overshadowed in a great degree the credit due to the original discoverer, and led to the universal adoption of the name of the Galilean telescope for the form of the instrument invented by Lippershey.

---

[1] He died about 1570. His son alludes to his untimely death in the preface to the *Pantometria*.

Kepler.

Gascoigne.

Kepler first explained the theory and some of the practical advantages of a telescope constructed of two convex lenses in his *Catoptrics* (1611). The first person who actually constructed a telescope of this form was Father Scheiner, who gives a description of it in his *Rosa Ursina* (1630). William Gascoigne was the first who practically appreciated the chief advantages of the form of telescope suggested by Kepler, viz., the visibility of the image of a distant object simultaneously with that of a small material object placed in the common focus of the two lenses. This led to his invention of the micrometer and his application of telescopic sights to astronomical instruments of precision (see MICROMETER, vol. xvi. p. 251). But it was not till about the middle of the 17th century that Kepler's telescope came into general use, and then, not so much because of the advantages pointed out by Gascoigne, but because its field of view was much larger than in the Galilean telescope.

Huygens.

Cassini.

Aerial telescopes.

The first powerful telescopes of this construction were made by Huygens, after much labor, in which he was assisted by his brother. With one of these of 12-feet focal length, he discovered the brightest of Saturn's satellites (Titan) in 1655, and in 1659 he published his *Systema Saturnium*, in which was given for the first time a true explanation of Saturn's ring, founded on observations made with the same instrument. The sharpness of image in Kepler's telescope is very inferior to that of the Galilean instrument, so that when a high magnifying power is required it becomes essential to increase the focal length. Cassini discovered Saturn's fifth satellite (Rhea) in 1672 with a telescope of 35 feet, and the third and fourth satellites in 1684 with telescopes made by Campani of 100 and 136 feet focal length. Huygens states that he and his brother made object-glasses of 170 and 210 feet focal length, and he presented one of 123 feet to the Royal Society of London. Auzout and others are said to have made telescopes of from 300 to 600 feet focus, but it does not appear that they were ever able to use them in practical observations. Bradley, on 27th December, 1722, actually measured the diameter of Venus with a telescope whose object-glass had a focal length of 212¼ feet. In these very long telescopes no tube was employed, and they were consequently termed *aerial telescopes*. Huygens contrived some ingenious arrangements for directing such telescopes towards any object visible in the heavens,—the focal adjustment and centring of the eye-piece being preserved by a braced rod connecting the object-glass and eye-piece. Other contrivances for the same purpose are described by La Hire (*Mém. de l' Acad.*, 1715) and by Hartsoeker (*Miscel. Berol.*, vol. i. p. 261). Telescopes of such great length were naturally difficult to use, and must have taxed to the utmost the skill and patience of the observers. One cannot but pay a passing tribute of admiration to the men who, with such troublesome tools, achieved such results.

Reflecting telescopes.

Gregory.

Newton.

Cassegrain.

Hadley.

Until Newton's discovery of the different refrangibility of light of different colors, it was generally supposed that object-glasses of telescopes were subject to no other errors than those which arose from the spherical figure of their surfaces, and the efforts of opticians were chiefly directed to the construction of lenses of other forms of curvature. James Gregory, in his *Optica Promota* (1663), discusses the forms of images of objects produced by lenses and mirrors, and shows that when the surfaces of the lenses or mirrors are portions of spheres the images are curves concave towards the objective, but if the curves of the surfaces are conic sections the spherical aberration is corrected. He was well aware of the failures of all attempts to perfect telescopes by employing lenses of various forms of curvature, and accordingly proposed the form of reflecting telescope which bears his name. But Gregory, according to his own confession, had no practical skill; he could find no optician capable of realizing his ideas, and after some fruitless attempts was obliged to abandon all hope of bringing his telescope into practical use. Newton was the first to construct a reflecting telescope. When in 1666 he made his discovery of the different refrangibility of light of different colors, he soon perceived that the faults of the refracting telescope were due much more to this cause than to the spherical figure of the lenses. He over-hastily concluded from some rough experiments (*Optics*, bk. i. pt. ii. prop. 3) "that all refracting substances diverged the prismatic colors in a constant proportion to their mean refraction"; and he drew the natural conclusion "that refraction could not be produced without color," and therefore "that no improvement could be expected from the refracting telescope" (*Treatise on Optics*, p. 112). But, having ascertained by experiment that for all colors of light the angle of incidence is equal to the angle of reflection, he turned his attention to the construction of reflecting telescopes. After much experiment he selected an alloy of tin and copper as the most suitable material for his specula, and he devised means for grinding and polishing them. He did not attempt the formation of a parabolic figure on account of the probable mechanical difficulties, and he had besides satisfied himself that the chromatic and not the spherical aberration formed the chief faults of previous telescopes. Newton's first telescope so far realized his expectations that he could see with its aid the satellites of Jupiter and the horns of Venus. Encouraged by this success, he made a second telescope of 6⅓-inches focal length, with a magnifying power of 38 diameters, which he presented to the Royal Society of London in December, 1671. A third form of reflecting telescope was devised in 1672 by Cassegrain (*Journal des Sçavans*, 1672). No further practical advance appears to have been made in the design or construction of the instrument till the year 1723, when John Hadley (best known as the inventor of the sextant) presented to the Royal Society a reflecting telescope of the Newtonian construction, with a metallic speculum of 6-inches aperture and 62⅝-inches focal length, having eye-pieces magnifying up to 230 diameters. The instrument was examined by Pound and Bradley, the former of whom reported upon it in *Phil. Trans.*, 1723, No. 378, p. 382. After remarking that Newton's telescope "had lain neglected these fifty years," they stated that Hadley had sufficiently shown "that this noble invention does not consist in bare theory." They compared its performance with that of the object-glass of 123-feet focal length presented to the Royal Society by Huygens, and found that Hadley's reflector

---

[1] This last power could not be exceeded with advantage in this form of telescope till after the invention of the achromatic object-glass.

> "will bear such a charge as to make it magnify the object as many times as the latter with its due charge, and that it represents objects as distinct, though not altogether so clear and bright. . . . Notwithstanding this difference in the brightness of the objects, we were able with this reflecting telescope to see whatever we have hitherto discovered with the Hugenian, particularly the transits of Jupiter's satellites and their shadows over his disk, the black list in Saturn's ring, and the edge of his shadow cast on his ring. We have also seen with it several times the five satellites of Saturn, in viewing of which this telescope had the advantage of the Hugenian at the time when we compared them; for, being in summer, and the Hugenian telescope being managed without a tube, the twilight prevented us from seeing in this some of these small objects which at the same time we could discern with the reflecting telescope."

James Short.

Bradley and Molyneux, having been instructed by Hadley in his methods of polishing specula, succeeded in producing some telescopes of considerable power, one of which had a focal length of 8 feet; and, Molyneux having communicated these methods to Scarlet and Hearn, two London opticians, the manufacture of telescopes as a matter of business was commenced by them (Smith's *Optics*, bk. iii. ch. 1). But it was reserved for James Short of Edinburgh to give practical effect to Gregory's original idea. Born at Edinburgh in 1710 and originally educated for the church, Short attracted the attention of Maclaurin, professor of mathematics at the university, who permitted him about 1732 to make use of his rooms in the college buildings for experiments in the construction of telescopes. In Short's first telescopes the specula were of glass, as suggested by Gregory, but he afterwards used metallic specula only, and succeeded in giving to them true parabolic and elliptic figures. Short then adopted telescope-making as his profession, which he practiced first in Edinburgh and afterwards in London. All Short's telescopes were of the Gregorian form, and some of them retain even to the present day their original high polish and sharp definition. Short died in London in 1768, having realized a considerable fortune by the exercise of his profession.

Achromatic telescopes.

Chester M. Hall.

Euler.

Klingenstierna.

Dollond.

The historical sequence of events now brings us to the discovery of the achromatic telescope. The first person who succeeded in making achromatic refracting telescopes seems to have been Chester Moor Hall, a gentleman of Essex. He argued that the different humors of the human eye so refract rays of light as to produce an image on the retina which is free from color, and he reasonably argued that it might be possible to produce a like result by combining lenses composed of different refracting media.[1] After devoting some time to the inquiry he found that by combining lenses formed of different kinds of glass the effect of the unequal refrangibility of light was corrected, and in 1733 he succeeded in constructing telescopes which exhibited objects free from color. One of these instruments of only 20-inches focal length had an aperture of 2½ inches. Hall was a man of independent means, and seems to have been careless of fame: at least he took no trouble to communicate his invention to the world. At a trial in Westminster Hall about the patent rights granted to Dollond (Watkin *v.* Dollond),[2] Hall was admitted to be the first inventor of the achromatic telescope; but it was ruled by Lord Mansfield that "it was not the person who locked his invention in his scrutoire that ought to profit for such invention, but he who brought it forth for the benefit of mankind."[3] In 1747, Euler communicated to the Berlin Academy of Sciences a memoir in which he endeavored to prove the possibility of correcting both the chromatic and the spherical aberration of an object-glass. Like Gregory and Hall, he argued that, since the various humors of the human eye were so combined as to produce a perfect image, it should be possible by suitable combinations of lenses of different refracting media to construct a perfect object-glass. Adopting a hypothetical law of the dispersion of differently colored rays of light, he proved analytically the possibility of constructing an achromatic object-glass composed of lenses of glass and water. But all his efforts to produce an actual object-glass of this construction were fruitless,—a failure which he attributed solely to the difficulty of procuring lenses worked precisely to the requisite curves (*Mem. Acad. Berlin*, 1753). Dollond admitted the accuracy of Euler's analysis, but disputed his hypothesis on the grounds that it was purely a theoretical assumption, that the theory was opposed to the results of Newton's experiments on the refrangibility of light, and that it was impossible to determine a physical law from analytical reasoning alone (*Phil. Trans.*, 1753, p. 289). In 1754 Euler communicated to the Berlin Academy a further memoir, in which, starting from the hypothesis that light consists of vibrations excited in an elastic fluid by luminous bodies, and that the difference of color of light is due to the greater or less frequency of these vibrations in a given time, he deduced his previous results. He did not doubt the accuracy of Newton's experiments quoted by Dollond, because he asserted that the difference between the law deduced by Newton and that which he assumed would not be rendered sensible by such an experiment.[4] Dollond did not reply to this memoir, but soon afterwards he received an abstract of a memoir by Klingenstierna, the Swedish mathematician and astronomer, which led him to doubt the accuracy of the results deduced by Newton on the dispersion of refracted light. Klingenstierna showed from purely geometrical considerations, fully appreciated by Dollond, that the results of Newton's experiments could not be brought into harmony with other universally accepted facts of refraction. Like a practical man, Dollond at once put his doubts to the test of experiment, confirmed the conclusions of Klingenstierna, discovered "a difference far beyond his hopes in the refractive qualities of different kinds of glass with respect to their divergency of colors," and was thus rapidly led to the construction of object-glasses in which first the chromatic and afterwards the spherical aberration were corrected (*Phil. Trans.*, 1758, p. 733).

---

[1] The same argument was employed by Gregory more than fifty years previously, but had been followed by no practical result. The lens of the human eye is not achromatic (see LIGHT, vol. xiv. p. 606).

[2] At a meeting of the Royal Astronomical Society held on 9th May, 1886, a legal document, signed by Chester Moor Hall, was presented by Mr. R. B. Prosser of the Patent Office to the society. On the same occasion Mr. Ranyard made the following interesting statement respecting Hall:

"Some years ago very little was known about Moor Hall. It was known that, about seven years after the patent for making achromatic object-glasses was granted to Dollond, his claim to the invention was disputed by other instrument-makers, amongst them by a Mr. Champness, an instrument-maker of Cornhill, who began to infringe the patent, alleging that John Dollond was not the real inventor, and that such telescopes had been made twenty-five years before the granting of his patent by Mr. Moor Hall. John Dollond, to whom the Copley medal of the Royal Society had been given for his invention, was then dead, and his son brought an action for infringing the patent against Champness. There is no report of the case, but the facts are referred to in the reports of subsequent cases. It appears that workmen who had been employed by Mr. Moor Hall were examined, and proved that they had made achromatic object-glasses as early as 1733. Dollond's patent was not set aside, though the evidence with regard to the prior manufacture was accepted by Lord Mansfield, who tried the case, as having been satisfactorily proved. . . . Mr. Hall was a bencher of the Inner Temple, and was alive at the time of the action. He was a man of some property, and is spoken of on his tombstone as an excellent lawyer and mathematician. He was not a fellow of the Royal Society, but must certainly have known of the gift of the Copley medal to Dollond. It is very curious the conflicting evidence we have to reconcile, but I think the balance of evidence is in favor of there having been a prior invention of achromatic object-glasses before the date of Dollond's patent" (*Astron. Register*, May, 1886; see also the *Observatory* for same date).

[3] *Gentleman's Magazine*, 1790, part ii. p. 890.

[4] For a good account of this controversy, see Dr. H. Servus, *Geschichte des Fernrohrs*, p. 77 *sq.*, Berlin, 1886.

We have thus followed somewhat minutely the history of the gradual process by which Dollond arrived independently at his invention of the refracting telescope, because it has been asserted that he borrowed the idea from others. Montucla, in his *Histoire des Mathématiques* (pp. 448–449), gives the following footnote, communicated to him by Lalande:

> "Ce fut Chestermonhall" (an obvious misprint for Chester Moor Hall) "qui, vers 1750, eut l'idée des lunettes achromatiques. Il s'adressoit à Ayscough,[1] qui faisoit travaillir Bass. Dollond ayant eu besoin de Bass pour un verre que demandoit le duc d'Yorck, Bass lui fit voir du crown-glass et du flint-glass. Hall donna une lunette à Ayscough, qui la montra à plusieurs personnes; il en donna la construction à Bird, qui n'en tint pas compte. Dollond en profita. Dans le procès qu'il y eut entre Dollond et Watkin, au banc du roi, cela fut prouvé; mais Dollond gagna, parce qu'il étoit le premier qui eût fait connoître les lunettes achromatiques."

It is clearly established that Hall was the first inventor of the achromatic telescope; but Dollond did not borrow the invention from Hall without acknowledgment in the manner suggested by Lalande. His discovery was beyond question an independent one. The whole history of his researches proves how fully he was aware of the conditions necessary for the attainment of achromatism in refracting telescopes, and he may be well excused if he so long placed implicit reliance on the accuracy of experiments made by so illustrious a philosopher as Newton. His writings sufficiently show that but for this confidence he would have arrived sooner at a discovery for which his mind was fully prepared. It is, besides, impossible to read Dollond's memoir (*Phil. Trans.*, 1758, p. 733) without being impressed with the fact that it is a truthful account, not only of the successive steps by which he independently arrived at his discovery, but also of the logical processes by which these steps were successively suggested to his mind.

The triple object-glass, consisting of a combination of two convex lenses of crown glass with a concave flint lens between them, was introduced in 1765 by Peter, son of John Dollond, and many excellent telescopes of this kind were made by him.

W. Herschel.

The limits of this article do not permit a further detailed historical statement of the various steps by which the powers of the telescope were developed. Indeed, in its practical form the principle of the instrument has remained unchanged from the time of the Dollonds to the present day; and the history of its development may be summed up as consisting not in new optical discoveries but in utilizing new appliances for figuring and polishing, improved material for specula and lenses, more refined means of testing, and more perfect and convenient methods of mounting. About the year 1774, William Herschel, then a teacher of music in Bath, began to occupy his leisure hours with the construction of specula, and finally devoted himself entirely to their construction and use. In 1778, he had selected the *chef d'œuvre* of some 400 specula which he made for the celebrated instrument of 7-feet focal length with which his early brilliant astronomical discoveries were made. In 1783 he completed his reflector of 18$\frac{7}{10}$-inches aperture and 20-feet focus, and in 1789 his great reflector of 4-feet aperture and 40-feet focal length. The fame of these instruments was rapidly spread by the brilliant discoveries which their maker's genius and perseverance accomplished by their aid. The reflecting telescope became the only available tool of the astronomer when great light grasp was requisite, as the difficulty of procuring disks of glass (especially of flint glass) of suitable purity and homogeneity limited the dimensions of the achromatic telescope. It was in vain that the French Academy of Sciences offered prizes for perfect disks of optical flint glass. Some of the best chemists and most enterprising glass-manufacturers exerted their utmost efforts without succeeding in producing perfect disks of more than 3½ inches in diameter. All the larger disks were crossed by striæ, or were otherwise deficient in the necessary homogeneity and purity.

Guinand.

Pierre Louis Guinand, a humble watchmaker living near Chaux de Fond in Neuchâtel, Switzerland, was the first who succeeded in making marked progress in the manufacture of optical flint glass. After making preliminary experiments extending over seven years (1784–90), and nothing daunted by their comparative want of success, he erected a furnace near Les Brenets, and devoted most of his slender earnings (then derived from making the bells, or rather gongs, of repeating watches) to the fulfilment of his ambition. His persistency, courage, and self-denial recall forcibly the story of Palissy. In 1805 he joined the optical establishment of Fraunhofer and Utzschneider and remained with them about nine years. During this period extensive experiments were instituted with remarkable success. It is said that the disks for the Dorpat refractor (9.6 inches aperture, with which the observations of Wilhelm Struve were made) were manufactured during this period, though the complete instrument was not delivered till 1823.

Fraunhofer.

Fraunhofer had, however, profited so fully by the suggestions of Guinand, and had probably also so far improved on the original methods, that he afterwards succeeded in producing still larger object-glasses. After Fraunhofer's death in 1826 his successors Merz and Mahler carried out successfully the methods handed down to them by Guinand and Fraunhofer, and produced some large and excellent telescopes, which are hereafter mentioned. Meanwhile Guinand, having returned to his native country in 1814, resumed there the manufacture of disks of optical glass, discovered a method of removing striæ by breaking and reuniting the portions by heat, when the glass was in a plastic state, and eventually produced perfect disks up to 18 inches in diameter. Most of these he disposed of to Lerebours and Secretan, opticians in Paris, by both of whom some fine object-glasses were made.[2] Guinand communicated his secrets to his sons before his death in 1823. About 1829 Bontemps entered into partnership with one of the sons, and another son carried on his father's manufacture in partnership with his mother. The latter firm was succeeded by Dauget of Soleure, whose exhibits of optical glass excited so much attention at the London exhibition of 1851. About 1848 Bontemps joined the firm of Chance Brothers of Birmingham, and thus carried the secret of Guinand's methods to England. It is not a little remarkable that the only firms in the world by whom large disks of optical glass have been produced trace their success to information derived more or less directly from Guinand. MM. Feil of Paris, who are direct descendants of Guinand, and Messrs. Chance Brothers of Birmingham are at the present time the only makers of optical glass in disks of larger diameter than 20 inches.

INSTRUMENTS, ETC.

We now proceed to give an account of the methods and principles of construction of the various kinds of telescopes, and to describe in detail special typical instruments, which, owing to the work accomplished by their aid or the practical advances exemplified in their construction, appear most worthy of record or study.

---

[1] Ayscough was an optician in Ludgate Hill, London.

[2] See Wolf, *Biographien*, vol. ii. p. 301, and Clerke, *History of Astronomy*, pp. 146–147.

Refracting Telescope.

Early forms.

In its simplest form the telescope consists of a convex object-lens capable of forming an image of a distant object and of an eye-lens, concave or convex, by which the image so formed is magnified. When the axis of the eye-lens coincides with that of the object-glass, and the focal point of the eye-lens is coincident with the principal focus of the object-lens, parallel rays incident upon the object-glass will emerge from the eye-piece as parallel rays. These, falling in turn on the lens of the human eye, are converged by it and form an image on the retina.[1] Fig. 1 shows the course of the rays when the eye-lens is convex (or positive), Fig. 2 when the eye-lens is concave (or negative). The former represents Kepler's, the latter Lippershey's or the Galilean telescope.[2] The magnifying power obviously depends on the proportion of the focal length of the object-lens to that of the eye-lens, that is,

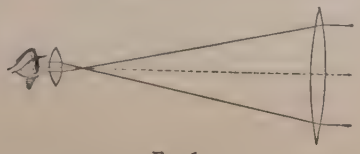

FIG. 1.

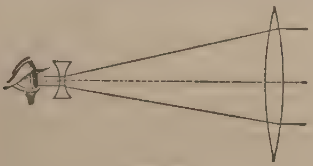

FIG. 2.

$$\text{magnifying power} = \text{F}/e,$$

where F is the focal length of the object-lens and *e* that of the eye-lens. Also the diameter of the pencil of parallel rays emerging from the eye-lens is to the diameter of the object-lens inversely as the magnifying power of the telescope. Hence one of the best methods of determining the magnifying power of a telescope is to measure the diameter of the emergent pencil of rays, after the telescope has been adjusted to focus upon a star, and to divide the diameter of the object-glass by the diameter of the emergent pencil. If we desire to utilize all the parallel rays which fall upon an object-glass it is necessary that the full pencil of emerging rays should enter the observer's eye. Assuming with Sir William Herschel that the normal pupil of the eye distends to one-fifth of an inch in diameter when viewing faint objects, we obtain the rule that the minimum magnifying power which can be efficiently employed is five times the diameter of the object-glass expressed in inches. The defects of the Galilean and Kepler telescopes are due to the chromatic and spherical aberration of the simple lenses of which they are composed (see OPTICS, vol. xvii. p. 827 *sq.*). The substitution of a positive or negative eye-piece for the simple convex or concave eye-lens, and of an achromatic object-glass for the simple object-lens, transforms these early forms into the modern achromatic telescope. The Galilean telescope with a concave eye-lens instead of an eye-piece still survives as the modern opera-glass, on account of its shorter length, but the object-glass and eye-lens are achromatic combinations.

Magnifying power.

Achromatic object-glass.

The principles of an achromatic combination of prisms or lenses have been explained in LIGHT (vol. xiv. pp. 596, 599) and further developed in OPTICS (vol. xvii. p. 829 *sq.*). As a lens may be regarded as built up of a series of thin slices of prisms, divided from each other by planes parallel to the axis of the lens, it will be seen that, if a prism perfectly achromatic for rays of two definite wave-lengths, and approximately achromatic for all rays, can be constructed by combining two prisms of different kinds of glass, all that is required to produce an object-glass with similar small chromatic errors is to combine a convex lens of crown glass and a concave one of flint glass as in Fig. 3, their surfaces being of such curvatures as to form a series of imaginary prisms (such as we have supposed an object-glass to consist of) through any one of which all kinds of light falling on the object-glass parallel to its axis will be refracted very nearly to a common focus F. Accordingly any proposed object-glass can be tested as regards its optical conditions by "tracing a ray," *i.e.*, calculating the point at which, after refraction through the two lenses, the ray so traced will cut their common axis. For the analytical solution of this problem it is necessary to assume that the adjacent surfaces of the supposed infinitely numerous prisms form together some continuous curved surface, which practically is nearly spherical. But the actual differences between the curves which may be required in certain conditions for producing a perfect lens differ so slightly from true spherical surfaces that it is impossible by any previously designed mechanical process to predict whether the resulting figure will be that of a sphere or some other curve very nearly that of a sphere. The mathematician, therefore, who discusses the subject is compelled to adopt spherical curves as the basis of his calculation. On this assumption we may then trace a ray rigidly through any supposed object-glass as follows. Let A, B, A′, B′ be respectively the points where the refracted ray produced would intersect the optical axis after refraction at the first, second, third, and fourth refracting surfaces respectively; also let a be the first angle of incidence, μ and μ' the refractive indexes for the crown and flint lens respectively for a ray of the wave-length whose course is to be traced, r and s the first and second radii for the crown lens, r' and s' the first and second radii for the flint lens, α, β, α', β', a', and b' auxiliary angles, d the thickness of the crown lens, d' the thickness of the flint lens, Δ the distance between the second and third surfaces. Then for the intersect after refraction at the first surface.

---

[1] In the case of short-sighted persons the image for very distant objects (that is, for parallel rays) is formed in front of the retina; therefore, to enable such persons to see distinctly, the rays emerging from the eye-piece must be slightly divergent; that is, they must enter the eye as if they proceeded from a comparatively near object. For normal eyes the natural adaptation is not to focus for quite parallel rays, but on objects at a moderate distance, and practically, therefore, most persons do adjust the focus of a telescope, for most distinct and easy vision, so that the rays emerge from the eye-piece very slightly divergent. Abnormally short-sighted persons require to push in the eye-lens nearer to the object-glass, and long-sighted persons to withdraw it from the adjustment employed by those of normal sight. It is usual, however, in computations of the magnifying power of telescopes, for the rays emerging from the eye-piece when adjusted for distinct vision to be parallel.

[2] [As Lippershey's telescope, with two lenses, inverted the object, as stated on p. 147, it could not have represented the Galilean telescope (Fig. 2) which does not invert the object.—AM. ED.]

$$\sin b = \frac{A + s - d}{s} \sin A ;$$

$$\sin \beta = \mu . \sin b ;$$

$$(B) = (A) + \beta - b ; \; B = \frac{s \sin \beta}{\sin (B)} - s ;$$

for the intersect after refraction at the third surface

$$\sin a' = -(B) - r' - \Delta) \frac{\sin (B)}{r'} ;$$

$$\sin a' = \frac{1}{\mu'} \sin a' ;$$

$$(A') = (B) + a' - a' ; \; A' = r - r' . \frac{\sin a}{\sin (A')}$$

for the intersect after refraction at the fourth surface

$$\sin b' = -(A' + s' - d') \sin \frac{(A')}{s'} ;$$

$$\sin \beta = \mu' \sin b ;$$

$$(B') = (A') + b' - \beta' ; \; B' = -s - s' . \frac{\sin \beta'}{\sin (B')} .$$

The computation is very much simplified when we consider the angle of incidence to be very small—*i.e.*, the point of incidence very near the optical axis, viz.,

$$\frac{r}{A} = \frac{\mu - 1}{\mu} ; \; \frac{s}{B} = \frac{\mu s}{A - d} + \mu - 1 ;$$

$$\frac{r'}{A'} = \frac{r'}{\mu' (B - \Delta)} + \frac{\mu' - 1}{\mu'} ; \; \frac{s'}{B'} = \frac{\mu' s'}{A' - d'} + \mu' - 1 .$$

Practical methods of computation.

By means of these formulæ we can compute B′ (the point where a ray, entering the first surface of the object-glass, will intersect the optical axis) for any angle of incidence $= a$, when for a ray of that wave-length the indexes of refraction are known for the glass of which the lenses are composed, if the radii of curvature of the lenses are also known. The most perfect object-glass would be one in which the value of B′ is the same for two rays of the two selected wave-lengths, through whatever portion of the object-glass they may pass. This, however, is a condition which cannot be mathematically satisfied with spherical surfaces. It is of course possible to find values of the four unknown quantities r, s, r', and s' such that four conditions shall be satisfied. The ordinary approximate method is to find such values of the radii that B′ is the same for rays of two different wave-lengths when the incident rays are near the axis, and for mean rays which enter near the margin of the lens; but of course this solution is indeterminate, and only becomes rigid when two radii are assumed. Thus, for any crown lens of any radii of curvature it is possible to find a flint lens to satisfy these conditions. The rigid solution becomes one of successive approximation to such four conditions as the computer may consider most desirable. Herschel advocates satisfying the terms depending on the second power of the aberration, Klügel that the refractions of the rays should be as small as possible; or we may make it a condition that the second and third surfaces shall have the same radius, so that the surfaces may be cemented together. The fourth condition is of course the desired focal length. But for all practical purposes it is sufficient to have placed the reader in a position to test the optical conditions of any combinations that may be proposed, and to refer him to the works mentioned in the subjoined note:[1] for, in in fact the construction of object-glasses on paper is of far higher interest as a mathematical exercise than as a practical matter. By a slight departure from the spherical figure—a departure so minute that there are no mechanical means sufficiently delicate to measure it with certainty—the optician may fail to realize true spherical surfaces, and thus on the one hand miss the fine definition which his calculation led him to expect, or on the other hand convert an object-glass which with spherical curves would have large spherical aberration into one perfectly corrected in this respect. Having, therefore, for particular kinds of glass ascertained a good general form of object-glass, it becomes only necessary for the optician to perform an approximate calculation of the curvatures requisite to produce correction of the chromatic aberration, and to trust to the process of final figuring for correction of the final spherical and chromatic aberration. It fortunately happens that in the rigid equations the terms which express the thickness and distance apart of the lenses involve only the focal distances of central rays, and have but a small influence on the ratios of the aberrations of the lenses; and, further, they affect chiefly the focal length of the lens, and have a very small influence on the chromatic aberration. Thus in the preliminary computation the optician may neglect the thickness of the lenses and employ the simple approximate formulæ given under OPTICS, vol. xvii. p. 827.

$$\frac{\delta\mu}{\mu - 1} \cdot \frac{1}{f} + \frac{\delta\mu'}{\mu' - 1} \cdot \frac{1}{f} = 0,$$

$$\frac{1}{F} = \frac{1}{f} + \frac{1}{f'},$$

where $\frac{\delta\mu}{\mu - 1}$ and $\frac{\delta\mu'}{\mu' - 1}$ are the dispersive powers of the two kinds of glass for the two rays which he desires to unite, f and f' the corresponding focal lengths of the two lenses, and F the focal length of the combination. The focal lengths of the two lenses which secure the conditions of achromatism having been thus computed, the radii of curvature may be computed for either lens by the usual formula (see LIGHT, vol. xiv. p. 599):

$$\frac{1}{f} = (\mu - 1) \left(\frac{1}{r} - \frac{1}{s} \right).$$

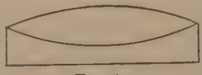

FIG. 4.

In the last expression, where r and s correspond to the radii of curvature, the optician has an infinite range of choice. He will of course select such a proportion of r to s as experience or more elaborate calculation has shown to be favorable. In the form of object-glass recommended by Sir John Herschel, as fulfilling the most favorable conditions for correction of a spherical aberration for parallel as well as nearly parallel rays, the required curvatures for the exterior surfaces of the crown and the flint lens were found to vary very slightly for a considerable range of the ratio of the dispersive powers of the crown and the flint glass. Assuming μ (the mean index of refraction) to be 1.542 for crown glass and 1.585 for flint glass, Herschel proved that, if the radii in question are taken to be 6.72 for the crown lens and 14.20 for the flint lens (supposing the focal length of the desired combination to be 10), we have only to compute the radii of the second and third surfaces by means of the above simple formulæ and the measured dispersive and refractive power of the glass of the lenses. (The method of determining μ, etc., is given under OPTICS, vol. xvii. p. 826.) The form generally adopted (see Fig. 4) in the best modern object-glasses is extremely simple, viz., an equi-convex crown lens and a flint lens whose first surface has the same radius of curvature as the surfaces of the crown lens—this radius depending on the focal length which it is desired to give to the object-glass. Since in order to fulfil the conditions of achromatism the focal lengths of the two lenses have to be proportional to their dispersive powers (for the rays which it is desired to unite), and as in the two descriptions of glass in question the dispersion of flint glass for C to rays between F and G is very nearly twice that of crown glass, the posterior surface of the flint lens becomes nearly a plane. The final correction for achromatism is made, if necessary, by departing slightly from a plane in the curvature of the last surface of the flint lens, and the final correction for spherical aberration in the figuring of the surfaces. In a lecture delivered at the Royal Institution on 2d April, 1886, Sir Howard Grubb, optician, of Dublin, said:

> "A truly spherical curve is the exception, not the rule. When I tell you that a sensible difference in correction for spherical aberration can be made by half an hour's polishing, corresponding probably to a difference in the first place of decimals in radii of the curves, you will see that it is practically not necessary to enter upon any calculation for spherical aberration. We know about what form gives an approximate correction; we adhere nearly to that, and the rest is done by figuring of the surface. To illustrate what I mean: I would be quite willing to undertake to alter the curves of the crown or flint lens of any of my objectives by a very large quantity, increasing one and decreasing the other so as to still satisfy the conditions of achromatism, but introducing theoretically a large amount of positive or negative spherical aberration, and yet to make out of the altered lens an object-glass perfectly corrected for spherical aberration. . . . I may remark that it is sometimes possible to make a better objective by deviating from the curves which give a true correction for spherical

aberration, and correcting that aberration by figuring, rather than by strictly adhering to the theoretical curves."

Color correction.

When an object-glass is designed for use as an ordinary telescope it is usual to select for the rays of different color to be united those near C and those between F and G, since rays of lower and higher refrangibility produce a comparatively faint impression on the sense of sight. In such a telescope of any considerable aperture the image of a bright star at focus is surrounded by a halo of bluish or violet-colored light,—a defect which is unavoidable in an object-glass composed of a crown and flint lens on account of the irrationality of their spectra (LIGHT, vol. xiv., p. 596). There seems to be no doubt that different eyes are differently impressed by rays of different wave-length.[1] Thus two observers will often have different opinions as to the chromatic corrections of the same object-glass: the observer whose eye is abnormally sensitive to violet light will pronounce the chromatic aberration over-corrected in an object-glass which another will consider perfect in this respect, and *vice versa*. Probably it is partly owing to this cause that the object-glasses of different makers show systematic differences in their color correction.

Correction for chromatic aberration.

An exceedingly sensitive method of testing this correction devised by Professor Stokes is given under OPTICS, vol. xvii. p. 828. Another method, due to Professor Harkness and first carried out by Dr. Vogel, is the following: Place behind the eye-piece a direct vision prism (*cf.* OPTICS, p. 825). The image of a star in the field will then be converted into a narrow spectrum, which, if there were no chromatic aberration, would when focused be represented by a faint colored straight line, uniformly sharp and narrow. But in an ordinary object-glass only two points in the spectrum can be perfectly focused simultaneously; therefore all its other parts are spread out, forming a colored band of variable breadth. If we focus on the brightest part of the spectrum, both its extreme ends become spread out into a more or less trumpet-shaped form, enabling the observer to note the range of the spectrum over which precise definition can be expected. The amount of this extension will depend in some degree on the form of the object-glass, but much more (if the achromatism is fairly well corrected) on the irrationality of the spectra of the glass of which the lenses are composed. If we then focus, for example, on the C line, we shall have the band of light contracted at C and at another point (probably between F and G), widening to a slightly trumpet-shaped form below C, and markedly so above G. This second point of greatest contraction gives the wave-length of the ray which has the same focus as C. If the telescope has a focusing scale, we can also measure directly in this way the change of focus for rays of different colors. The chromatic aberration will be best corrected for the rays of minimum focus, and this minimum focus should for an ordinary telescope correspond with the brightest part of the spectrum, viz., with rays between D and E. A comparison of the chromatic correction of object-glasses by different makers is given by Dr. Vogel (*Monatsber. der Berliner Akad.*, April, 1880), obtained in the manner just described. The telescopes compared are:

Maker.	Observatory to which Instrument belongs.	Aperture of Object-Glass.	Focal Length.	No. of Apertures in Focal Length
		m.	m.	
Schröder.....	Potsdam.	0.298	5.4	18.1
Grubb	"	0.207	3.16	15.3
Fraunhofer.	Berlin.	0.243	4.331	17.8

Fig. 5, taken from the above-quoted paper, affords most interesting information as to the color-correction of these three typical object-glasses. The curves of the diagram show the variation of the focal point for rays of different wave-lengths in the case of each object-glass. It will be seen that Fraunhofer has united the rays about C with those of wave-length 525 millionths millimètres, Grubb with those about wave-length 494, and Schröder about wave-length 463. The object-glasses of Grubb and Schröder are composed of modern glass, which is comparatively colorless, whilst Fraunhofer's glass is decidedly green in color. The minimum focus in Fraunhofer's telescope is placed near D (rather at wave-length 585), because the absorption of the blue and violet rays of the spectrum by the flint lens renders the brightest part of the spectrum less blue than in an objective composed of modern glass by Chance or Feil, which is nearly colorless. This circumstance enabled Fraunhofer to apply a very large over-correction for color,—that is, to unite as perfectly as possible the red and central part of the spectrum, and to leave the outstanding violet rays to be in great part absorbed by the color of the glass. The color-corrections in the object-glasses of Grubb and Schröder are very different in character. In Grubb's object-glass the minimum focus is for rays of wave-length about 545, that of Schröder's is about wave-length 533, which appears to prove that Grubb's eye is more sensitive to red and Schröder's to blue light. Also Grubb's object-glass unites the red rays very closely with the brightest part of the spectrum, and leaves the blue and violet rays outstanding. Schröder, on the other hand, leaves the red rays outstanding in order to unite the rays between D and

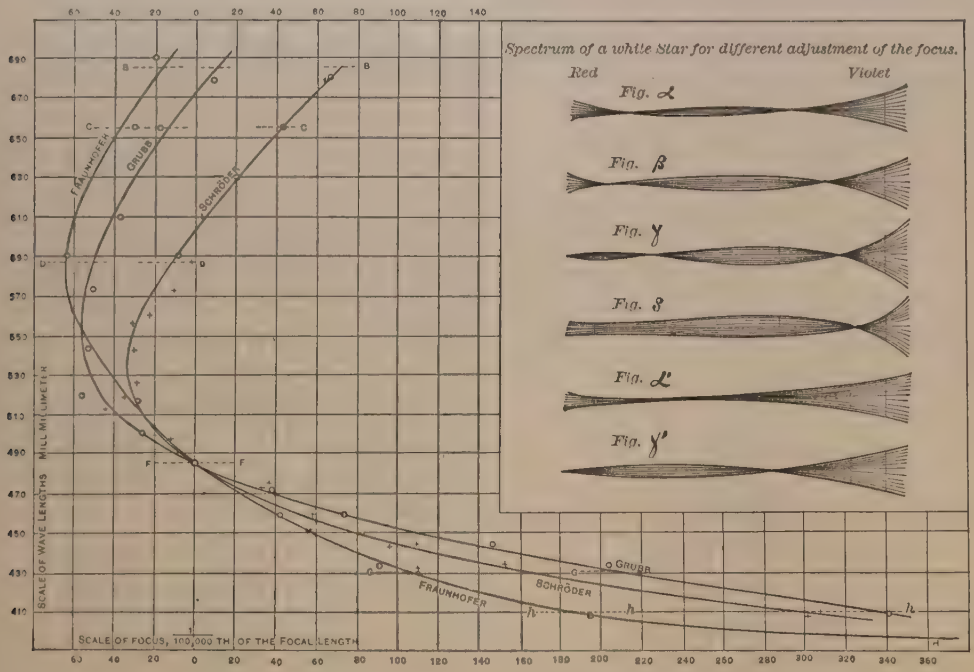

FIG. 5.

---

[1] See Abney and Festing, Bakerian Lecture, *Phil. Trans.*, 1886; also *Photographic News*, May, 1886, p. 332.

F more closely. The conclusion is that to Grubb's eye the red rays would be obtrusively prominent in Schröder's telescope, and that he would pronounce the object-glass under-corrected; whilst Schröder's eye would find the outstanding violet rays too prominent in Grubb's telescope, and pronounce it over-corrected. The absolute amount of light in the secondary spectrum in viewing the same object depends, *cæteris paribus*, upon the square of the aperture; therefore telescopes of large aperture have to be made of greater proportional focal length than those of small aperture, in order to diminish the secondary spectrum. Figs. $\alpha, \beta, \gamma, \delta$ in the diagram give the form of the spectrum of a star in Schröder's telescope for various adjustments of the focus; Figs. α' and γ' give the corresponding forms for Fraunhofer's telescope. Fig. α represents the eye-piece focused for the brightest part of the spectrum; Fig. β when the red rays and those near Hα are simultaneously focused; Fig. γ when the extreme red rays are in focus, the corresponding focus being a little below Hγ; Fig. δ when focused on Hγ.

Photographic object-glasses.

When a telescope is to be constructed for photographic purposes the aim should be to unite, as perfectly as possible, the rays near that portion of the spectrum which act most powerfully on the photographic plate to be employed. This latter point has been determined for the various photographic processes by Captain Abney.[1] The results are shown graphically in Fig. 6 for the processes practically employed at present in astronomical photography.

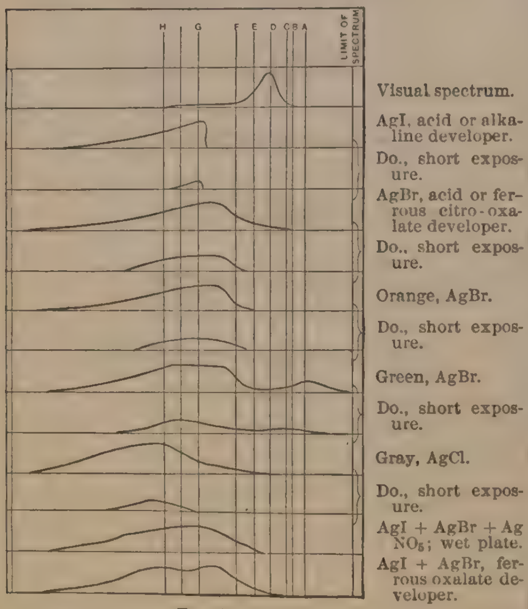

FIG. 6.

To unite the rays near G or H the angle of the flint prism must be diminished; that is, the focal length of the flint lens must be lengthened as compared with that of an object-glass of similar construction suited for eye observations; and the rays of greatest photographic action can be united more perfectly than the visible rays.

Triple object-glasses.

If an object-glass is composed of three lenses of different kinds of glass it is theoretically possible to unite three instead of two points of the spectrum, besides improving the correction for spherical aberration. The most important practical applications of such a system have been—(1) the triple object-glass of John Dollond; (2) the application of a convex crown glass in front of an ordinary object-glass in order to alter its chromatic correction from that best suited for eye observations to that best suited for photographic observation. John Dollond's object-glass is generally described as a concave flint lens between two crown lenses. If the crown lenses are of similar glass, there is no gain as to the correction of the secondary spectrum; it becomes only possible to correct the spherical aberration more perfectly. Very few telescopes with triple object-glasses have been made since the days of John Dollond. But the great and detrimental obtrusiveness of the secondary spectrum in the large object-glasses of the present day can be diminished in no other way, unless very extreme focal lengths are adopted, or some new kinds of glass that can be produced in large disks are discovered, in which the irrationality of their spectra is less, and in which also there is the necessary difference in the relation between refractive index and dispersive power. The cost of a triple object-glass would of course be at least 50 per cent. greater than that of a double object-glass; but, on the other hand, the extreme focal length necessary for large object-glasses might be considerably reduced. Thus the cost saved by a less heavy mounting and a smaller observatory and dome might counterbalance to some extent, if not entirely, the additional cost of the triple object-glass. Dr. Schröder has constructed for the present writer an exquisite triple object-glass (three different kinds of glass) of 3½-inches aperture and only 18-inches focal length. Its performance with its highest eye-piece of ¼-inch focus (power 72) is most admirable. It would probably be impossible to construct large telescopes approaching such short focal length, but there is no doubt that a large triple object-glass of 10 or 12 apertures focus would have an enormous advantage in color correction, and probably in spherical aberration, over a double object-glass of the same aperture and much greater focal length. One peculiarity of such a triple object-glass is that three points in the spectrum can have the same focus, and therefore the point of minimum focus may for the best chromatic adjustment not quite correspond with the focal point for the brightest part of the spectrum; but, obviously, the rays of the whole visible spectrum may thus be brought to intersect the axis much more nearly at the same point. There will probably be a far wider adoption of the triple object-glass in the future, especially as the greater intrinsic brilliancy of the image in short-focus telescopes is a matter of high importance in the spectroscopic and photographic processes of modern astronomy. On the subject of triple object-glasses the reader is referred to an admirable paper by Professor C. S. Hastings (*Amer. Journal of Science and Arts* for December, 1879, p. 429), which exhibits the results to be got from combinations of different existing kinds of glass.

The following table exhibits the excess of the focus for any ray over the true focus, the unit being $\frac{1}{100000}$ of the focal length, in—I. the actual results of Dr. Vogel's observations on three existing object-glasses already quoted, but each reduced to comparison with its true or minimum focus; II. the theoretically best possible results from a double object-glass consisting of Feil's crown 1219 and Feil's flint 1237, as computed by Hastings; III. the theoretical results of four different triple object-glasses, capable of practical construction, of which details are given by Hastings.

	Double Object-Glasses.				Triple Object-Glasses.			
	I.			II.	III.			
	Fraunhofer.	Grubb.	Schröder.	Hastings.	Hast. 1	Hast. 2	Hast. 3	Hast. 4
A	..	..	..	+ 135	..	+ 2	..	— 3
B	+ 47	+ 64	+ 106	+ 66	+ 1	— 53	— 22	— 35
C	+ 36	+ 41	+ 78	+ 41	0	+ 41	+ 91	+ 50
D	0	+ 8	+ 23	0	0	+ 28	+ 41	+ 2
E	+ 27	+ 29	0	+ 13	+ 25	— 10	— 67	— 10
F	+ 64	+ 56	+ 33	+ 73	0	— 14	— 60	— 4
G	+ 171	+ 226	+ 243	+ 287	0	+ 2	+ 21	— 3

Prof. Hastings's first condition in these computations is that the radius of curvature of none of the surfaces shall exceed one-fifteenth of the focal length. He also neglects the thickness and distance apart of the lenses, since these affect chiefly the focal length, but do not very materially affect the difference of the foci for different rays. The expression for the focal length F is then

$$\phi=(\mu'-1)\left(\frac{1}{r_1}+\frac{1}{r_2}\right)+(\mu''-1)\left(\frac{1}{r_3}+\frac{1}{r_4}\right)+(\mu'''-1)\left(\frac{1}{r_5}+\frac{1}{r_6}\right),$$

where $\phi=\frac{1}{F}$, μ', μ'', μ''' are the indexes of refraction for the three kinds of glass, and $r_1, r_2, \ldots r_6$ the radii of curvature for the six successive surfaces. Writing this in the form

$$\phi=(\mu'-1)A+(\mu''-1)B+(\mu'''-1)C,$$

we may call A, B, and C the *curvature sums* of the first, second, and third lenses respectively. The problem then is to find, for existing specimens of glass, values of A, B, and C no one of which shall exceed 30 when $\phi=1$, and which shall make ϕ independent of the wave-length of the light transmitted. The resulting values of A, B, and C for the first combination (marked "Hastings 1") are

---

A	B	C
3.47026	7.20327	—8.35472;

the curvatures are therefore very moderate and perfectly practicable. The constants for the glass of the first and second lenses have been determined by the author with great accuracy (see *Amer. Jour.*, vol. xv. p. 273). The third glass is Fraunhofer's flint 13 (Hastings ι, misprinted ν in his table, in *Amer. Jour.*, vol. xviii. p. 131), for which the constants are given in Schumacher's *Astron. Abhandlung für* 1823. If this glass can be reproduced in large disks, as no doubt it could be, we have the means of making an object-glass very superior to any in existence and equally available for eye and photographic observation. Such an object-glass could be made of much shorter proportional focus than is usual or possible in double object-glasses, not only because of the absence of secondary spectrum but also from the command afforded over the spherical aberration by six surfaces. After satisfying the conditions of focal length, the first power of the spherical aberration, and two conditions of achromatism, we have still two available arbitrary conditions, which may be that $r_2 = r_3$ and $r_4 = r_5$. If these lead to convenient forms, as seems likely in the case in point, the whole may constitute a cemented lens; thus the loss of light at the interior surfaces may be eliminated, and the final perfecting of the spherical aberration be left to the figuring of the surfaces.

Change of chromatic correction by separating lenses.

In some recent large double object-glasses, especially those of Alvan Clark, it has been usual to leave a space between the crown and the flint lens sufficient to afford access, through apertures in the cell, for cleaning the inner crown and flint surfaces, without risk of disturbing the lenses and their centring.[1] If in Fig. 3 we imagine the lenses to be considerably separated and through both lenses trace a ray entering the crown lens parallel to and at some distance from the axis, we shall find that the effect of the separation is to diminish the power of the flint lens, and therefore to change the character of the chromatic aberration. Thus an object-glass over-corrected for color can be improved in this respect by increasing the distance between the lenses. It has been suggested that a telescope can be made suitable for both eye observation and photographic purposes if means are provided for increasing the distance between the lenses without risk of deranging the centring when the telescope is to be employed for photography. But the great change that would be necessary in such a case cannot be brought about consistently with preservation of the perfection of the corrections for spherical aberration.[2]

Vernon Harcourt's phosphatic glasses.

Any account of the achromatic object-glass would be incomplete without reference to the labors of the Rev. W. Vernon Harcourt and Prof. Stokes. Experiments in the production of optical glass were instituted by the former in 1834; and specimens, exhibited at the meeting of the British Association at Cambridge in 1862, were placed in the hands of Prof. Stokes, who determined the optical constants of the numerous specimens of glass which Harcourt produced, and indicated from these results the direction in which fresh experiments should be undertaken. It was discovered that titanic acid extends the blue end of the spectrum more than corresponds to the dispersive power of the glass, whilst boracic acid has the opposite effect (*Report Brit. Assoc.*, 1871, p. 38). At a meeting of the British Association at Belfast in 1874 a telescope was exhibited whose object-glass was constructed from Harcourt's glass by Sir Howard Grubb of Dublin. The following is Prof. Stokes's complete and concise account of it.

> "The original intention was to construct the objective of a phosphatic glass containing a suitable percentage of titanic acid, achromatized by a glass of terborate of lead. (The percentage of titanic acid was so chosen that there should be no irrationality of dispersion between the titanic glass and the terborate.) As the curvature of the convex lens would be rather severe if the whole convex power were thrown into a single lens, it was intended to use two lenses of this glass, one in front and one behind, with the concave terborate of lead placed between them. It was found that, provided not more than about one-third of the convex power were thrown behind, the adjacent surfaces might be made to fit, consistently with the condition of destroying the spherical as well as the chromatic aberration. This would render it possible to cement the glasses, and thereby protect the terborate, which was rather liable to tarnish. At the time of Mr. Harcourt's death two disks of the titanic glass had been prepared which it was hoped would be good enough for employment, as also two disks of terborate. These were placed in Mr. Grubb's hands. On polishing, one of the titanic disks was found to be too badly striated to be employed; the other was pretty fair. As it would have required a rather severe curvature of the first surface and an unusual convexity of the last to throw the whole convex power into the first lens, using a mere shell of glass to protect the terborate, Professor Stokes thought it more prudent to throw about one-sixth of the whole convex power into the third or crown glass lens, though at the sacrifice of an *absolute* destruction of secondary dispersion, which by this change from the original design might be expected to be just barely perceptible. Of the terborate disks, the less striated happened to be slightly muddy, from some accident in the preparation; but, as this signified less than the striæ, Mr. Grubb deemed it better to employ this disk. The telescope exhibited to the meeting was of about 2½-inches aperture and 28-inches focal length, and was provided with an object-glass of the ordinary kind, by which the other could be replaced, for contrasting the performance. When the telescope was turned on to a chimney seen against the sky or other suitable object, and half the object-glass covered by a screen with its edge parallel to the edges of the object, in the case of the ordinary objective vivid green and purple were seen about the two edges, whereas with the Harcourt objective there was barely any perceptible color. It was not of course to be expected that the performance of the telescope should be good, on account of the difficulty of preparing glass free from striæ, but it was quite sufficient to show the possibility of destroying the secondary color."

An experiment to determine whether the substitution of titantic acid for a portion of the silica in ordinary crown glass would have an effect similar to that which had been observed in the phosphatic series of glasses (viz., whilst somewhat raising the dispersive power, to produce a separation of the colors at the blue as compared with the red end of the spectrum, to an extent ordinarily belonging only to glass of much higher dispersive power) was carried out by Mr. Hopkinson at the glass works of Messrs. Chance of Birmingham; but it proved unfortunately in this combination that, whilst the dispersive power was increased, as in the phosphatic glasses, the blue end of the spectrum, as compared with the red end, was not spread out more than in ordinary glass of like dispersive power (*Report Brit. Assoc.*, 1875, p. 26). It is to be hoped, however, that makers of optical glass will not relax their efforts till astronomers shall be able to obtain refracting telescopes in which the secondary spectrum is nearly if not quite eliminated. Abbe's new optical glass[3] leads one to believe that this hope will soon be realized.

A third or photographic lens.

The addition of a convex crown lens in front of the ordinary object-glass, to diminish the color-correction and change the minimum focus from that for rays between D and E to that for rays near G, was first made by Rutherford of New York. In this way he altered his telescope from one suited for eye observations to one in the best chromatic adjustment for photographic work. The chromatic effect is the same as increasing the convexity of the crown lens, and by proper proportioning of the two radii of curvature it becomes possible also to conserve, and even to further perfect, the destruction of spherical aberration. The great object-glass of 36-inches aperture, now (1887) under construction for the Lick observatory by Messrs. Clarke of Boston (Mass.), is to be provided with an additional crown lens for this purpose.[4]

Blair's achromatic fluid object-glasses.

The problem of making a perfectly achromatic object-glass has been solved by Dr. Blair (*Edin. Trans.*, vol. iii. p. 53) by employing fluid media, and he actually constructed an object-glass consisting of a plano-convex lens and a meniscus lens, both of crown glass with their convexities turned towards each other, the space between the lenses being filled with hydrochloric acid. Unfortunately such combinations are practically useless, not only on account of unavoidable leakage, but also because currents are set up in fluid lenses by changes of temperature, which correspond in effect with want of homogeneity in the flint lens in an ordinary object-glass.

---

[1] This arrangement also helps to equalize the temperatures of the lenses with each other and with the outer air.

[2] Quite recently Prof. Stokes has suggested that to adapt a telescope to either photographic or telescopic purposes at pleasure the crown lens should be reversible as well as changeable as to distance with respect to the flint. In this way doubtless the chromatic and spherical aberration could be preserved for the two kinds of work.

[3] See *Nature*, vol. xxxiv. p. 622, 26th October, 1886.

Safarik, *Vierteljahrschrift der astronomischen Gesellschaft*, 1882, pp. 13–39.

Eye-Pieces.

Eye-pieces.

The first substitute for the single lens of the Galilean and Kepler telescopes was the compound eye-piece invented by Rheita. Behind the convex eye-lens of the Kepler telescope he applied a second short telescope, consisting of two convex lenses, their distance being the sum of their focal lengths. The principal effect was to erect the inverted image, and thus to constitute the simplest form of the day eye-piece, or common terrestrial telescope. The next improvement was the Huygenian eye-piece, which consists of two convex lenses (see Fig. 7),—the "field-lens," that next the object-glass, having its focal length to that of the "eye-lens" as 3 to 1; the distance between them is twice the focal length of the latter, the combination being so placed as to form the visible image half-way between the two. This eye-piece is achromatic in the sense in which an eye-piece is said to be so; a colorless image seen through it does not appear bordered with colored fringes, as is the case with a single lens or Rheita's eye-piece. This is not because, as in the achromatic object-glass, all the central colored rays are collected in one focus, which in the case of an eye-piece is a matter of comparatively small consequence, but because it possesses the same magnifying power for rays of all colors on an object of sensible angular diameter, so as not to form overlapping colored pictures of it on the retina. This condition it is which furnishes the "equation of achromaticity" of an eye-piece. An expression for the magnifying power of a telescope provided with a certain eye-piece is formed in general terms which involve the focal length of its lenses, their distances from each other, and their refractive indexes; and, this being made to vary by the variation of the last-mentioned elements only, the variation is equated to zero. The algebraic working, which even for a two-glass eye-piece is a little complex, is given in H. Lloyd's *Treatise on Light and Vision* (London, 1831), and in an elaborate paper by Littrow in the fourth volume of the *Trans. Roy. Astron. Soc.* (p. 599). From the former we extract the following proposition: An eye-glass of two lenses of the same medium is achromatic when the interval between the lenses is an arithmetical mean between their focal length,—a condition which the Huygenian construction evidently satisfies. The rationale of this is obvious, independently of algebraic analysis, by inspection of the course of the rays in Fig. 7, where AC, BD are the lenses, PQ the image which would be formed by the object-glass alone, *pq* that really formed by the action of the field-glass. The object-glass being supposed achromatic, a ray of white light, as OC, going to form the image of a point Q, will be refracted by the field-glass at C towards the corresponding point *q* of the new image, but not as a single white ray; it will be separated into colored rays, following different courses. The red ray C*r* being less refracted will fall on a point *r* of the eye-glass more remote from its centre B than the violet ray C*v*, and (the prismaticity of the lens increasing from the centre outwards) will in proportion by the second transmission be more bent aside than the violet, and thus a compensation is effected, and the two rays finally emerge parallel, their exact parallelism being secured by the proportion of their focal lengths. The Huygenian eye-piece possesses also other important advantages. The total deflection of the light, to produce the magnifying power, is equally divided between the two glasses,—the most favorable condition for diminishing that distortion which is always perceived in looking obliquely through a lens; and the field of view is greatly enlarged in proportion to the size of the eye-lens, being such as would require, to produce the same magnifying power, a single lens of the much greater semi-diameter *bd*, found by drawing Q*b* parallel to *q*B and erecting *bd*. The inconvenience of this eye-piece (whence it is improperly termed a negative eye-piece) is that the image, being formed between its lenses, undergoes a certain amount of distortion by the field-glass, owing to which equal linear portions of it do not correspond precisely to equal angular measures of the distant object. Equal parts of a micrometer applied at the place of the image, so as to be seen at the same time through the eye-lens, will not correspond to precisely equal angular intervals. The common astronomical or positive eye-piece, described by Ramsden (*Phil. Trans.*, 1783), consists of two plano-convex lenses of equal lengths, having their convexities turned towards each other and separated by two-thirds of the focal length of either, as in Fig. 8.

Huygenian eye-piece.

Common or positive eye-piece.

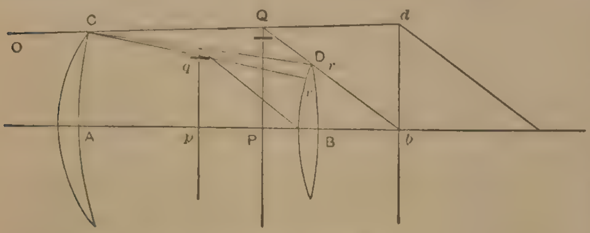

Fig. 7.—Huygenian eye-piece.

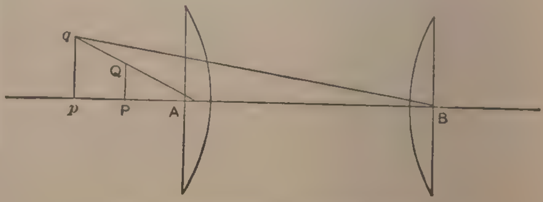

Fig. 8.—Common or positive eye-piece.

Erecting or terrestrial eye-piece.

This combination is placed behind the image PQ formed by the object-glass, at a distance AP equal to one-fourth of the focal length of A. The first or field-glass, therefore, forms an enlarged image *pq*, at a distance one-third of that focal length which places it in the focus of the eye-glass. This eye-piece is not properly achromatic, but its spherical aberration is much less than in any of the other constructions, and it has the advantage of giving a flat field of view, requiring no change of focus to see the centre and borders of the field with equal distinctness. The erecting or terrestrial eye-piece was invented by Dollond. The principle of its construction will be understood from Fig. 9. It is convenient for telescopes of ordinary use, because it presents a non-inverted image to the eye, although at some sacrifice of light and definition.

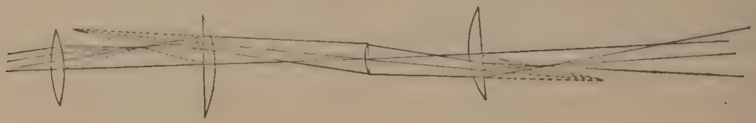

Fig. 9.—Erecting or terrestrial eye-piece.

Airy on eye-pieces.

For an account of the theory of the chromatic and spherical aberration of eye-pieces by Sir George B. Airy, see *Trans. Phil. Soc. Camb.*, vol. ii. p. 243 and vol. iii. p. 61. The author's conclusions are the following: (1) To secure the greatest distinctness with an eye-piece of the Huygenian type, the field-lens should be a meniscus of focal length 3, the radii of its surfaces 11 : 4, and its convexity towards the object-glass; the eye-lens should be a double convex of focal length 1, the radii of its surfaces 1 : 6, and its more convex side towards the field-lens. The distance of the lenses should be 2. There should be a perforated diaphragm at distance 1 from the eye-lens. If a bright object appears yellow or a dark one blue at the edge farthest from the centre of the field, the lenses must be brought a little nearer together. (2) For an eye-piece of Ramsden's type the two lenses should be plano-convex, of focal length 3, placed at distance 2, their convex surfaces being turned towards each other. (3) For an erecting eye-piece of four lenses the first and fourth (reckoned from the object-glass towards the eye) should be crossed lenses of focal length 3, the radii of their surfaces 1 : 6, with their convex surfaces towards each other. The second lens should be a meniscus of focal length 4, the radii of its surfaces 25 : 11, and its convexity towards the eye. The third lens should be plano-convex, of focal length 4, its plane side towards the eye. The distance of the centre of the second lens from that of the first = 4; that of the third from the second = 6; and that of the fourth from the third = 5.13. If a bright object appears yellow or a dark one blue at the edge farthest from the centre of the field, the third and fourth lenses must be together pushed inwards towards the second lens.

In many telescopes constructed specially for star observation only the object-glass is over-corrected for color and under-corrected for spherical aberration; both these errors may sometimes be nearly eliminated by a properly constructed Huygenian eye-piece (see MICROSCOPE, vol. xvi. p. 277). But, when a telescope is to be used over a considerable range of field for micrometric measurements, it is obvious that the spherical aberration should be corrected by the object-glass alone. It is possible, however, to improve the appearance of objects somewhat in a telescope in which the chromatic aberration is over-corrected by employing an eye-piece somewhat under-corrected for color, and *vice versa;* but the only satisfactory plan is to have both object-glass and eye-piece as free as possible from both chromatic and spherical aberration. In order to secure this, or a very large field of view, many forms of eye-piece have been devised. Achromatic combinations have been substituted in some cases for the field-lens, in others for the eye-lens, in others for both simple lenses of the Ramsden eye-piece. The best of these combinations which the present writer has tested and which practically fulfil all requirements of the astronomer are due to Dr. Hugo Schröder, to whom he is indebted for information as to their construction. Fig. 10 represents Schröder's high power eye-piece, which is admirably suited for micrometer work, not only because there are only two reflecting surfaces in the triple lens of which it is composed, but also because there is a comparatively large distance between the lens and the micrometer web when the latter is in focus. This condition is essential when it is desired to get the best bright illumination of the wires in a dark field (see MICROMETER, vol. xvi. p. 258). The triple lens is composed of a dense fluid plano-convex lens between two lenses of soft crown glass. The radii of curvature are:

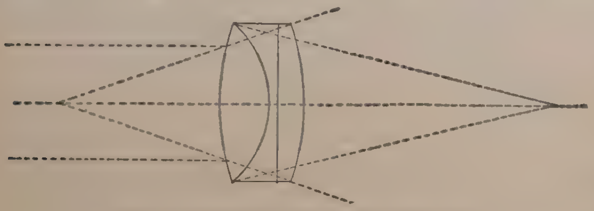

FIG. 10.—Schröder's high power eye-piece.

H. Schröder's high power eye-piece.

$$\begin{array}{rl} & r_1 = 80.026 \text{ convex} \\ \text{surfaces} & r_2 = 36.536 \text{ convex} \\ \text{cemented} & r_3 = 36.536 \text{ concave} \\ \text{surfaces} & r_4 = \infty \text{ plane} \\ \text{cemented} & r_5 = \infty \text{ plane} \\ & r_6 = 80.026 \text{ convex} \end{array} \left.\begin{array}{l} \text{soft crown glass,} \\ \\ \text{dense flint glass,} \\ \\ \text{soft crown glass.} \\ \\ \end{array}\right.$$

The corresponding foci for zones of different distance from the axis are: axis = 100.00; zones 12.5 from axis, 99.81; 25 from axis, 99.32; 40 from axis, 93.35; 45 from axis, 100.15; 50 from axis, 101.85. Thus the aperture of the lens may be half its focal length without any sensible defect. Fig. 11 represents Dr. O. Schröder's aplanatic eye-piece. The glass employed is Dauget's crown (Cb_1) and flint (Fb_1). The refractive power of crown is 1.5126 for D, that of flint 1.6405; the dispersive power of both kinds of glass is 0.588.

O. Schröder's aplanatic eye-piece.

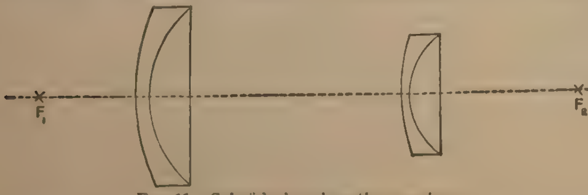

FIG. 11.—Schröder's aplanatic eye-piece.

The radii of curvature for a lens of 1 inch (27.07 mm.) focal length are:

mm.	mm.
$r_1 = 20.12$	$r_5 = 13.30$
$r_2 = r_3 = 10.94$ cemented	$r_6 = r_7 = 7.00$ cemented
$r_4 = \infty$	$r_8 = \infty$

F_1 = focal point of combination = —9.05 mm. from vertex of r_1; F_2 = position of observer's eye = —14.49 mm. from vertex of r_8.

The thicknesses and distances apart of the surfaces are—

1st vertex to 2d = 0.70 mm. flint glass,
3d " " 4th = 3.50 " crown glass,
4th " " 5th = 19.51 " air,
5th " " 6th = 0.61 " flint glass,
7th " " 8th = 2.45 " crown glass.

The distance between the plane surfaces is 22.57 mm. This form of eye-piece has been employed by Schönfeld in his southern "Durchmusterung," and Dr. Schröder has made one for the present writer which gives a perfect field 4¼° in diameter on the telescope of 18 inches focal length and 3¼ inches aperture already referred to.

Reflecting Telescope.

Gregorian telescope.

The following are the various forms of reflecting telescopes. The Gregorian telescope is represented in Fig. 12. AA and BB are concave mirrors having a common axis and their concavities facing each other. The focus of A for parallel rays is at F, that of B for parallel rays at *f*—between B and F. Parallel rays falling on AA converge at F, where an image is formed; the rays are then reflected from B and converge at P, where a second and more enlarged image is formed. Gregory himself showed that, if the large mirror were a segment of a paraboloid of revolution whose focus is F, and the small mirror an ellipsoid of revolution whose foci are F and P respectively, the resulting image will be plane and undistorted. The image formed at P is viewed through the eye-piece at E, which may be of the Huygenian or Ramsden type. The focal adjustment is accomplished by the screw S, which acts on a slide carrying an arm to which the mirror B is attached. The practical difficulty of constructing Gregorian telescopes of good defining quality is very considerable, because if spherical mirrors are employed their aberrations tend to increase each other, and it is extremely difficult to give a true elliptic figure to the necessarily deep concavity of the small speculum. Short appears to have systematically conquered this difficulty, and his Gregorian telescopes attained great celebrity. The use of the Gregorian form is, however, practically abandoned in the present day. The magnifying power of the telescope is $= \frac{F+f}{e+x}$, where F and *f* are respectively the focal lengths of the large and the small mirror, *e* the focal length of the eye-piece, and *x* the distance between the principal foci of the two mirrors (= F*f* in the diagram) when the instrument is in adjustment for viewing distant objects. The images are erect.

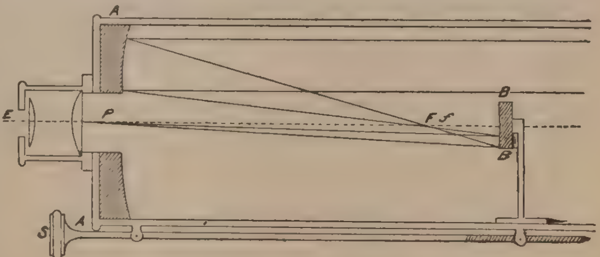

FIG. 12.—Gregorian telescope.

Cassegrain telescope.

The Cassegrain telescope differs from the Gregorian only in the substitution of a convex hyperbolic mirror for a concave elliptical mirror as the small speculum. This form has two distinct advantages: (1) if spherical mirrors are employed their aberrations have a tendency to correct each other; (2) the instrument is shorter than the Gregorian, *cæteris paribus*, by twice the focal length of the small mirror. Fewer telescopes have been made of this than perhaps of any other form of reflector; but in comparatively recent years the Cassegrain has acquired importance from the fact of its adoption for the great Melbourne telescope. The magnifying power is computed by the same formula as in the case of the Gregorian telescope.

Newtonian.

The Newtonian telescope is represented in Fig. 13. AA is a concave mirror whose axis is *aa*. Parallel rays falling on AA converge on the plane mirror BB, and are thence reflected at right angles to the axis, forming an image in the focus of the eye-piece E. The surface of the large mirror should be a paraboloid of revolution, that of the small mirror a true optical plane. The magnifying power is $=F/e$. This form is employed in the construction of most modern reflecting telescopes. A glass prism of total reflection is sometimes substituted for the plane mirror.

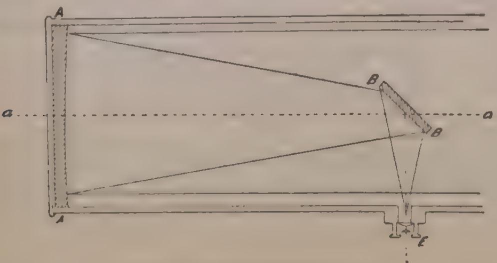

Fig. 13.—Newtonian telescope.

Herschelian

The Herschelian or front view reflector is represented in Fig. 14. AA is a concave parabolic mirror, whose axis *ac* is inclined to the axis of the tube *ab* so that the image of an object in the focus of the mirror may be viewed by an eye-piece at E, the angle *bac* being equal to the angle *ca*E. This form was adopted by the elder Herschel to avoid the loss of light from reflection in the small mirror of the Newtonian telescope. It has several disadvantages. (1) The upper part of the observer's head must necessarily obstruct some of the rays which would otherwise fall on the large mirror; but when a telescope of very large aperture is employed the loss of light thus occasioned is comparatively insignificant. Moreover, disturbance of the air in front of the telescope is created by heat from the observer's head and body, and this is fatal to the best definition. To avoid the latter drawback Sir John Herschel (*Ency. Brit.*, 8th ed., art. "Telescope," vol. xxi. p. 128) suggested the employment of a small right-angled prism of total reflection placed close to the eye-lens of the eye-piece, to permit the observer to view the image by looking in a direction at right angles to the eye-piece, and therefore at right angles to the tube. (2) In consequence of the tilting of the mirror aberration is created, and this increases rapidly with increased tilting. The construction is thus limited to telescopes in which the proportion of aperture to focal length is not too great. In Herschel's 40-feet telescope the proportion was 1 to 10, and the construction would hardly be applicable to modern telescopes, in which the proportion often rises to 1 to 5 or 6. Yet, when exceedingly faint objects have to be observed, this form of telescope has great advantages. Herschel found that some objects which he discovered with such an instrument could not even be seen with the same telescope when used in the Newtonian form. The front view telescope, however, has hardly been at all employed except by the Herschels. But at the same time none but the Herschels have swept the whole sky for the discovery of faint nebulæ; and probably no other astronomers have worked for so many hours on end for so many nights as they did, and they emphasize the easy position of the observer in using this form of instrument.

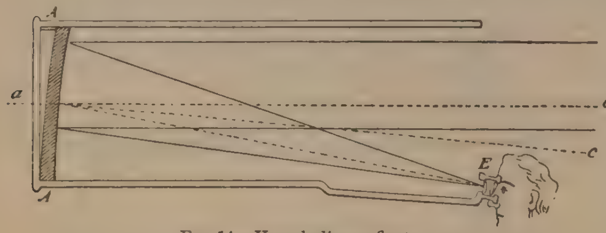

Fig. 14.—Herschelian reflector.

Construction of Object-Glasses.

Testing object-glasses.

The first point is the selection of glass disks of suitable quality. The requisites are (1) general transparency and freedom from mechanical defects, such as specks, air-bubbles, etc.; (2) homogeneity; (3) freedom from internal strain. The disk being roughly polished on the sides, faults of the first class are easily detected by inspection. In order to secure the maximum of light grasp for aperture it is desirable that the glass should be as colorless as possible; if the roughly polished disk is laid upon white paper the amount of discoloration can be readily estimated by comparing the color of the sheet as seen directly with that seen through the glass. Fraunhofer's glass was far from colorless. Dollond's more colored still; and we have shown that, for purposes when extreme light grasp is not an object, the less transparency of such glass to the blue rays of the spectrum affords advantages for a better correction of the chromatic aberration of rays in the brighter part of the spectrum. The amount of light excluded by specks, air-bubbles, or even scratches is quite insignificant; but these blemishes create diffraction phenomena and scattered light in the field, which are very injurious to the performance of the instrument, especially when faint objects are searched for in the neighborhood of brighter ones. It is essential for a telescope lens that the glass should be perfectly homogeneous; that is, the refractive index must be identical for every part of the disk. This can be tested with extreme delicacy by grinding the disk into the form of a lens and testing it by Töppler's method,[1] described under Optics (vol. xvii. p. 828). If the disk is intended for a concave lens and is already so thin that it becomes undesirable to make it thinner at the edges by converting it, in the first place, into a convex lens, it may be tested by placing one of its surfaces in contact with and at right angles to the axis of a crown lens of known perfection, and testing the combination by Töppler's method. If a glass disk is not properly annealed—that is, if it has been too quickly cooled, so that the outer shell has hardened before the inner portion—the finally solidified mass must be in a state of tension, like that of "Rupert's drops." Unless cooled very gradually an optical disk would fly to pieces, but a very much smaller defect in the annealing process would be fatal for refined optical purposes. Changes of temperature would produce changes of curvature, and the lens would also change its form when successive portions of the strained outer shell were removed in the process of grinding and polishing. Fortunately defects in annealing are very easily detected by means of the polariscope. The polished disk is placed in light reflected from a polarizing surface, such as a sheet of glass blackened at the back, and examined with a Nicol's prism as an analyzer. If the bright rings and black cross (see Light, vol. xiv. p. 617) are visible, the disk is unfit for use; but, since few disks are so perfectly annealed as not to show a trace of the black cross, such as show it in no marked degree may be safely employed. Perfect annealing has now become the most difficult portion of the art of making optical glass, and large disks (more particularly of crown glass) are rejected by the optician more frequently for defects in annealing than for any other cause.

Annealing.

The disks having been selected, their refractive and dispersive powers determined, and the radii of curvature computed, it remains to convert the disks into lenses with surfaces of the required curvature, and to complete the object-glass. The work consists of five distinct operations—(1) rough grinding by a revolving tool supplied with sand and water; (2) fine grinding with emery; (3) polishing with oxide of iron, rouge, or putty powder, the grinder being faced with fine cloth, satin, paper, or—best of all—pitch; (4) centring; (5) figuring and testing. These processes are essentially of a technical character, and can only be familiar to those who practice the art. The details would be out of place here, but are well described in a lecture delivered by Sir Howard Grubb at the Royal Institution, 6th April, 1886, and printed in *Nature*, 27th May, 1886.

Construction of Specula.

Construction of specula.

The composition of metallic specula in the present day differs very little from that used by Sir Isaac Newton. Many different alloys have been suggested, some including silver, nickel, zinc, or arsenic; but that which has practically been found best is an alloy of four equivalents of copper to one of tin, or the following proportions by weight: copper 252, tin 117.8. Such speculum metal is exceedingly hard and brittle, takes a fine white polish, and when protected from damp has little liability to tarnish. The process of casting and annealing, in the case of the specula of the great Melbourne telescope, was admirably described by Dr. Robinson in *Phil. Trans.*, 1869, vol. clix. p. 135. Shaping, polishing, and figuring of specula are accomplished by methods and tools precisely similar to those employed in the construction of lenses. The reflecting surface is first ground to a spherical form, the parabolic figure being given in the final process by regulating the size of the pitch squares and the stroke of the polishing machine. The process of testing is identical with that of an object-glass.

---

[1] *Pogg. Annal.*, cxxxi., 1867.

Soon after Liebig's discovery of a process for depositing a film of pure metallic silver upon glass from a salt of silver in solution, Steinheil (*Gaz. Univ. d'Augsburg*, 24th March, 1856), and later, independently, Foucault (*Comptes Rendus*, vol. xliv., February, 1857), proposed to employ glass for the specula of telescopes, the reflecting surface of the glass speculum to be covered with silver by Liebig's process. These silver-on-glass specula are now the rivals of the achromatic telescope, and it is not probable that many telescopes with metal specula will be made in the future. The best speculum metal and the greatest care are no guarantee of freedom from tarnish, and, if such a mirror is much exposed, as it must be in the hands of an active observer, frequent repolishing will be necessary. This involves refiguring, which is the most delicate and costly process of all. Every time, therefore, that a speculum is repolished, the future quality of the instrument is at stake; its focal length will probably be altered, and thus the value of the constants of the micrometer also have to be redetermined. Partly for these reasons the reflecting telescope with metallic mirror has never been a favorite with the professional astronomer, and has found little employment out of England. In England, in the hands of the Herschels, Rosse, Lassell, and De la Rue it has done splendid service, but in all these cases the astronomer and the instrument-maker were one.[1] The silver-on-glass mirror has the enormous advantage that it can be resilvered with little trouble, at small expense, and without danger of changing the figure. Its chief work has been done in the hands of Draper and Common, who were the engineers, if not the actual constructors, of their own instruments. Glass is lighter, stiffer, less costly, and easier to work than speculum metal. The silvered mirrors have also some advantage in light grasp over those of speculum metal, though, aperture for aperture, the former are inferior to the modern object-glass. Comparisons of light grasp derived from small, fresh, carefully silvered surfaces are sometimes given which lead to illusory results, and from such experiments Foucault claimed superiority for the silvered speculum over the object-glass. But the present writer has found from experience and careful comparison that a silvered mirror of 12-inches aperture mounted as a Newtonian telescope (with a silvered plane for the small mirror), when the surfaces are in fair average condition, is equal in light grasp to a first-rate refractor of 10-inches aperture, or area for area as 2 : 3. This ratio will become more equal for larger sizes on account of the additional thickness of larger object-glasses and the consequent additional absorption of light in transmission.

Mounting of Telescopes.

Mounting of telescopes.

The proper mounting of a telescope is hardly of less importance than its optical perfection. Freedom from tremor, ease and delicacy of movement, facility of directing the instrument to any desired point in the heavens, are the primary qualifications. Our limits forbid an historical account of the earlier endeavors to fulfil these ends by means of motions in altitude and azimuth, nor can we do more than refer to mountings such as those employed by the Herschels, or those designed by Lord Rosse to overcome the engineering difficulties of mounting his huge telescope of 6 feet aperture. Both are abundantly illustrated in most popular works on astronomy, and it seems sufficient to refer the reader to the original descriptions.[2]

Equatorial.

We pass, therefore, directly to the equatorial telescope, the instrument *par excellence* of the modern extra-meridian astronomer, and relegate to the article TRANSIT CIRCLE (*q.v.*) a description of those mountings in which the telescope is simply a refined substitute for the sights or pinules of the old astronomers. The equatorial in its simplest form consists of an axis parallel to the earth's axis, called the "polar axis;" a second axis, at right angles to this, called the "declination axis"; and a telescope fixed at right angles to the latter. In Fig. 15 AA is the polar axis; the telescope is attached to the end of the declination axis; the latter rotates in bearings attached to the polar axis, and concealed by the telescope itself. The telescope is counterpoised by a weight attached to the opposite end of the declination axis. The lower pivot of the polar axis rests on a cup bearing at C, the upper pivot upon a strong metal casting MM, attached to a stone pier S. A vertical plane passing through AA is therefore in the meridian, and, when the declination axis is horizontal, the telescope moves in the plane of the meridian by rotation on the declination axis only. Thus, if a graduated circle BB is attached to the declination axis, together with the necessary microscopes or verniers V, V for reading it (see TRANSIT CIRCLE), so arranged that when the telescope is turned on the declination axis till it is parallel to AA the vernier reads 0° or 90°, and when at right angles to AA 90° or 0°, then we can employ the readings of this circle to measure the polar distance or declination of any star seen in the telescope, and these readings will also be true (apart from the effects of atmospheric refraction) if we rotate the instrument through any angle on the axis AA. Thus one important attribute of an equatorially mounted telescope is that, if it is directed to any fixed star, it will follow the diurnal motion of that star from rising to setting by rotation of the polar axis only. If we further attach to the polar axis a graduated circle DD, called the "hour circle," of which the microscope or vernier R reads 0^h when the declination axis is horizontal, we can obviously read off the hour angle from the meridian of any star to which the telescope may be directed at the instant of observation. If the local sidereal time of the observation is known, the right ascension of the star becomes known by adding the observed hour angle to the sidereal time if the star is west of the meridian, or subtracting it if east of the meridian. Since the equatorial is unsuitable for such observations when great accuracy is required (see TRANSIT CIRCLE), the declination and hour circles of an equatorial are employed not for determination of the right ascensions and declinations of celestial objects, but for directing the telescope with ease and certainty to any object situated in a known position, and which may or may not be visible to the unaided eye, or to define approximately the position of an unknown object. Further, by causing the hour circle, and with it the polar axis, to rotate by clockwork or some other mechanical contrivance at the same angular velocity as the earth on its axis, but in the opposite direction, the telescope will automatically follow a star from rising to setting.

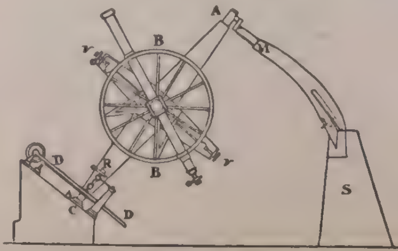

FIG. 15.—Equatorial telescope.

Types of equatorials.

Equatorial mountings may be divided into five types. (A) The pivots or bearings of the polar axis are placed at its extremities. The declination axis rests on bearings attached to opposite sides of the polar axis. The telescope is attached to one end of the declination axis, and counterpoised by a weight at the other end, as in Fig. 15. (B) The polar axis is supported as in type A; the telescope is placed between the bearings of the declination axis and is mounted symmetrically with respect to the polar axis; no counterpoise is therefore requisite. (C) The declination axis is mounted on the prolongation of the upper pivot of the polar axis; the telescope is placed at one end of the declination axis and counterpoised by a weight at the other end. (D) The declination axis is mounted on a forked piece or other similar contrivance attached to a prolongation of the upper pivot of the polar axis; the telescope is mounted between the pivots of the declination axis. (E) The eye-piece of the telescope is placed in the upper pivot of the polar axis; a portion or the whole of the axis of the telescope tube coincides with the polar axis. Mountings of types A and B—that is, with a long polar axis supported at both ends—are often called the "English mounting," and types C and D, in which the declination axis is placed on the extension of the upper pivot of the polar axis, are called the "German mounting," from the first employment of type C by Fraunhofer. A description of some of the best examples of each type will illustrate their relative advantages or peculiarities.

---

[1] [The prize of 2500 francs offered by the Academie des Sciences of France for a satisfactory method of silvering mirrors was awarded to M. Lenoir. His process was to silver the glass by means of tartaric acid and ammoniacal silver nitrate and then expose it to a weak solution of double cyanide of mercury and potassium. Then fine zinc-dust is powdered over the surface to reduce the quicksilver of the cyanide and thus form a brilliant silver amalgam on the glass.—AM. ED.]

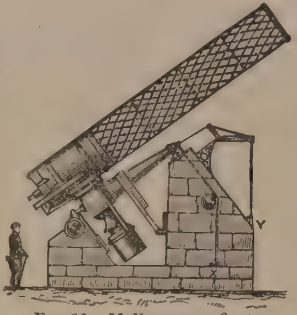

FIG. 16.—Melbourne reflector.

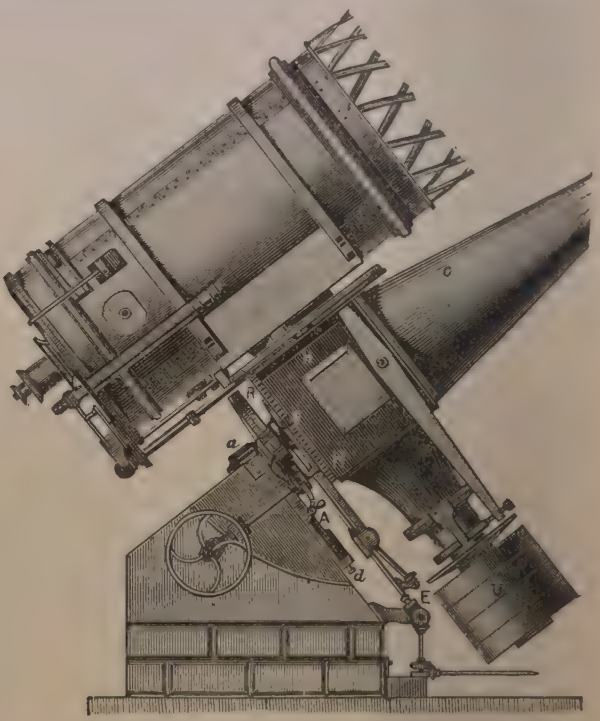

FIG. 17.—Section of Melbourne reflector.

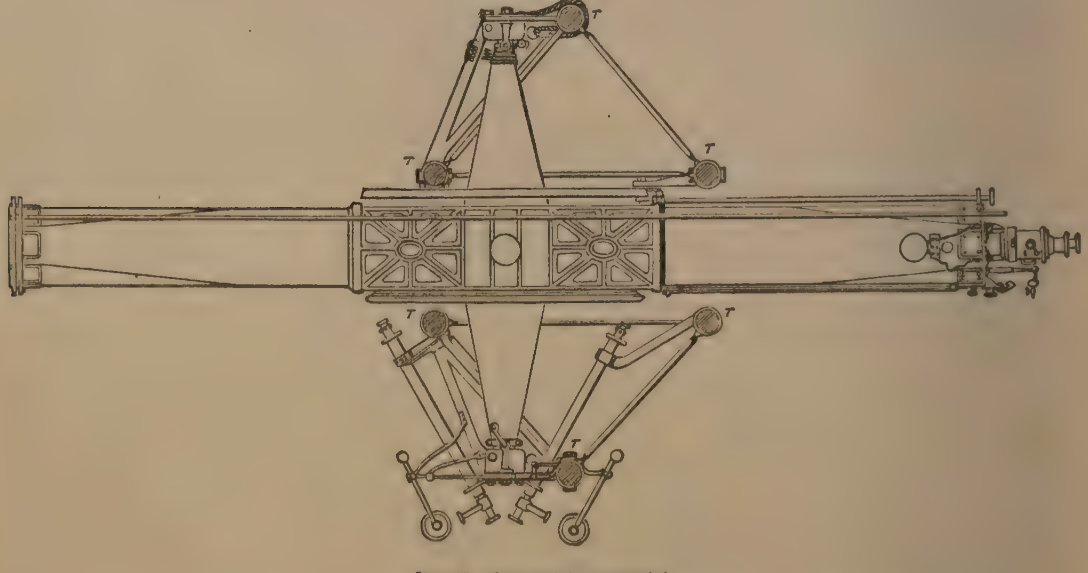

FIG. 18.—Greenwich equatorial.

Type A.

Fig. 15 may be taken as a practical example of the earlier equatorials as made by Troughton in England and afterwards by Gambey for various Continental observatories. In the *Phil. Trans.* for 1824 (part 3, pp. 1-412) will be found a description by Sir John Herschel and Sir James South of the equatorial telescope which they employed in their measurements of double stars. The polar axis was similar in shape to that of Fig. 15 and was composed of sheets of tinned iron. In Smyth's celebrated Bedford telescope the polar axis was of mahogany.

Great Melbourne telescope.

Probably the best example of this type of mounting applied to a refractor is that made by the elder Cooke of York for Mr. Fletcher of Tarnbank; the polar axis is of cast iron and the mounting very satisfactory and convenient, but unfortunately no detailed description has been published. In recent years no noteworthy refractors have been mounted on this plan; but type A has been chosen by Grubb for the great Melbourne reflector, with marked ingenuity of adaptation to the peculiar requirements of the case. Fig. 16 shows the whole instrument on a small scale, and Fig. 17 represents part of it on a larger scale, the upper part of the tube and polar axis being omitted. The figures show the telescope directed to the pole, the hour circle being set 6^h from the meridian. The polar axis consists of a hollow cone C (Fig. 17) of cast-iron bolted to a hollow cast-iron cube H, to the lower side of which is attached a short steel axis carrying the driving sector EF and the hour circle R, and terminating in the lower pivot of the polar axis. This pivot *a* is terminated by a piece of chilled cast iron polished flat on its lower face, which face revolves in contact with a piece of bell metal, flat on its upper and partly spherical on its lower side, bearing in a correspondingly shaped annulus, formed to receive it in the cast-iron block which is attached to the pier. This arrangement enables the bell-metal cushion to take its own position when the direction of the polar axis is slightly changed in process of adjustment. The pressure of the pivot on its bearings, in the direction at right angles to the polar axis, is relieved by the sector A, which is forced up by the screw *d* acting through laminæ of steel springs. The end pressure of *a* upon its bearings is relieved by a weight. The friction of the upper pivot is relieved by a sector pressed up against it by the action of two weights. In this way, although the moving part of the telescope weighs 18,170 ℔, it can be turned with a pressure of 12½ ℔, acting at a radius of 20 feet. The driving sector EF is 5 feet in radius; its circular rim is accurately toothed to fit a square threaded endless screw E, which is turned by the driving clock. A toothed wheel attached to H and acted on by a pinion connected with a hand-wheel affords an easy means of setting the instrument in hour angle, or moving the telescope quickly in right ascension. The telescope is clamped by iron bands to the strong cast-iron cradle, which is cast with and forms one extremity of the declination axis. The counterpoise U is attached to the other extremity. There is an elegant arrangement for diminishing the friction of the declination axis, which our limits do not permit us to describe, and the means for clamping and giving slow motion in declination do not require special notice. The reader is referred for a fuller description to *Phil. Trans.*, 1869, pp. 127–161. The telescope is of the Cassegrain form, the mirror having a 4-feet aperture and 30½-feet focal length.

Type B.

Greenwich equatorial.

The best existing examples of type B are Airy's equatorial at Greenwhich, the equatorial at Liverpool (also designed by Airy), and the photographic equatorial recently erected at the Paris observatory. The polar axis of the Greenwich equatorial consists of six iron tubes arranged so as to form two triangular braced beams connected by very strong elliptical wheels of cast iron, which carry the upper and lower pivots of the polar axis. These tubes are shown in section at the points T, Fig. 18, which represents a section through the declination axis in the plane of the equator when the telescope is directed to a star at the equator (for the general arrangement of the mounting, see Fig. 19). The driving circle is 6 feet in diameter, and turns freely on the lower pivot of the polar axis, under the action of the driving clock. The hour circle is graduated on the driving circle, and may be set to show sidereal time during the whole of a night's work; thus the observer, in order to direct the instrument on a particular object, has only to set an index connected with the polar axis to the star's right ascension upon the hour circle, without the trouble of computing the hour angle at the instant of observation. This convenient arrangement was first introduced by Airy. The whole mounting is very massive, but very inconvenient to use when a great many different objects have to be examined on the same night; but on account of its freedom from tremor and the excellence of its driving clock it should be very suitable for prolonged study of a single object or for long photographic exposures.[1] Quite recently Sir Howard Grubb has signed a contract to make a telescope of 28-inches aperture and 28-feet focal length,[2] which is to be substituted for the present telescope by Merz & Son of 12⅔-inches aperture and 18-feet focus. Fig. 19 is engraved from a photograph of the model of the original polar axis. The model was prepared to illustrate the manner in which the new telescope is to be mounted, and we are indebted for the picture to the kindness of Mr. Christie, astronomer royal. The object-glass will be actually outside the dome when the telescope is pointed near the zenith or near the horizon. The dew-cap, not shown in the model, will be always outside the dome, and it is not impossible that this arrangement may be favorable to good definition, except in case of high wind. When the telescope is not in use the dew-cap slides backwards on four rails parallel to the axis of the telescope, and the whole is housed in the position shown in Fig. 19. The spectroscope is used at right angles to the telescope tube, a right-angled prism of total reflection being interposed in the converging cone of rays near the focus. This prism can be turned 180° and an eye-piece inserted on the opposite side from the spectroscope for observations near the zenith or horizon, otherwise the eye end would be too near the floor or northern pier.[3]

New Greenwich telescope.

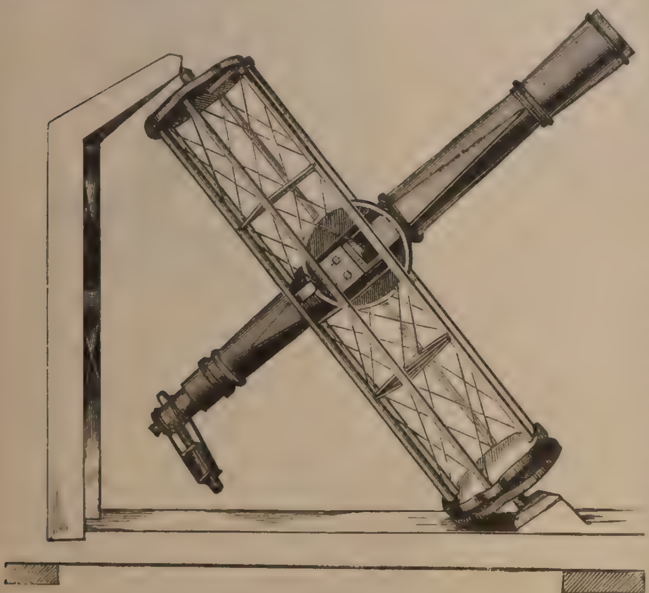

FIG. 19.—Grubb's telescope for Greenwich.

Paris photographic telescope.

A figure of the new photographic telescope erected at the Paris observatory may be seen in *Nature*, 13th May, 1886. The object-glass is by MM. Paul and Prosper Henry, the mounting by M. Gautier. Here Airy's braced tubes are replaced by hollow metal beams of triangular shape (as for the Liverpool equatorial). The hour circle has two toothed circles cut upon it, one acted upon by a screw attached to the pier and driven by the clock, the other by a second screw attached to the polar axis, which can be turned very slowly by a handle in the observer's hand. Thus a very slow movement can be given to the telescope in right ascension, independently of the clock. Slow motion in declination can be communicated by a screw acting on a long arm, which can be clamped at pleasure to the polar axis by a convenient handle. An oblong metallic box, fitted with pivots, whose bearings are attached to the triangular beams, forms the tube for two parallel telescopes; these are separated throughout their length by a metallic diaphragm. The chromatic aberration of the object-glass of one of these telescopes is corrected for photographic rays, and the image formed by it is received on a highly sensitive photographic plate. The other telescope is corrected for visual rays and its image is formed on the plane of the spider lines of a filar micrometer. The peculiar form of the tube is eminently suited for rigid preservation of the relative parallelism of the axes of the two telescopes, so that, if a certain selected star is retained in bisection by two intersecting wires in the micrometer, by means of the driving clock, aided by small corrections given by the observer in right ascension and declination (required on account of irregularity in the clock movement, error in astronomical adjustment of the polar axis, or changes in the star's apparent place produced by refraction), the image of a star will continue on the same spot of the photographic plate during the whole time of exposure. Exquisite photographs of star clusters, double stars, the moon, and planets have been obtained by MM. Henry, and they are the most eloquent testimony to the optical perfection of the object-glass and the efficiency of the mounting. They show also that we are entering upon a new era in practical astronomy, in which photography is destined to play a leading part. The Henry photographic object-glass is of 13.4 inches aperture and only 10 apertures in focal length. The "guiding telescope" is of 9½-inches aperture and nearly 12-feet focus. The photographic object-glass, notwithstanding its small proportional focal length, covers a field of 2½° in diameter with perfect precision.

Type C.

Dorpat refractor.

Many more telescopes have been made of type C than of any other, and it is now almost exclusively employed for the mounting of modern refractors. Its essential features are (1) a comparatively short polar axis and (2) a cross-head attached to the extension of the upper pivot of the polar axis, to carry the bearings of the declination axis. Fig. 20 shows the Dorpat refractor, the *chef d'œuvre*

The following table gives the focal length in apertures of the largest existing refractors:

Vienna telescope	(Grubb)	27-in. aperture,	focal length	15.5 apertures
Washington "	(Clark)	26 "	"	15.0 "
Pulkowa "	(Clark)	30 "	"	18.0 "

---

[1] See the detailed account in *Greenwich Observations*, 1868.

[2] This object-glass will have the shortest proportional focal length of any yet constructed of aperture exceeding 16 inches.

[3] These inconvenient conditions are imposed by the dimensions of the existing dome and may lead to accidents in practice.

of Fraunhofer, and the first equatorial of any importance that was provided with clockwork. AA is the polar axis, B the hour circle graduated on the face and read by the vernier V. C′ is the driving clock, which turns an endless screw S, that gears in the toothed edge of the circle B. D is the cross-head supporting at its extremities the bearings of the declination axis. The wooden telescope tube rests in a strong cradle FF of cast brass, which is screwed to a flange on one end of the declination axis; the declination circle EE, which is attached to its opposite end, serves to clamp the instrument in declination to the arm G. H is a weight acting on a lever which presses the wheels *k* (one only seen in the figure) against the upper pivot of the polar axis in order to relieve the friction of that pivot on its bearing. The counterpoise W balances the tube about the polar axis. M, M are counterpoise weights which act on levers *m*, *m*, whose fulcra are universal joints at *n* attached to the cradle. These weights serve to counterpoise the longer end of the tube and to check its flexure. QQ is the finder, a small telescope whose axis is parallel to the great telescope; having a low magnifying power and a large field of view, it serves to direct the large telescope to any object seen in the sky, which otherwise would be difficult to find in the comparatively limited field of the large telescope. The stand TTT is of oak. The instrument is described in detail by Struve (*Beschreibung des auf der Sternwarte zu Dorpat befindlichen grossen Refractors von Fraunhofer*, Dorpat, 1825, fol.). The instrument was an enormous advance upon all previous telescopes for micrometric research. In the hands of Struve results were obtained by it which in combined quality and quantity had never before been reached in micrometric research. Its success was such that the type of Fraunhofer's telescope became stereotyped for many years not only by his successors but throughout Germany. When twelve years afterwards Struve ordered the 15-inch refractor for the new observatory at Pulkowa, the only important change made by Fraunhofer's successors was, at Struve's suggestion, the substitution of a stone pier for the wooden stand in the original instrument.

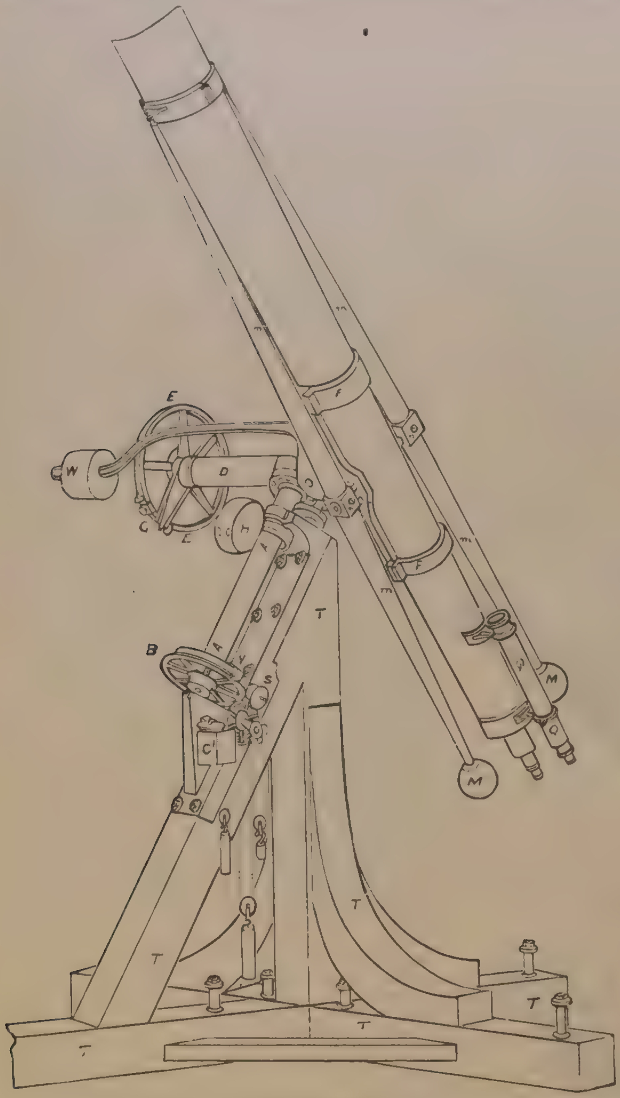

Fig. 20.—Dorpat refractor.

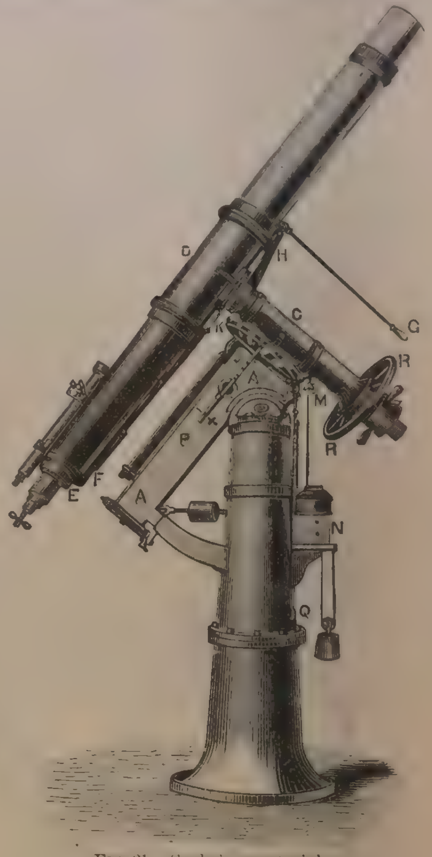

Fig. 21.—Cooke's equatorial.

Both the Dorpat and the Pulkowa refractor are defective in rigidity, especially in right ascension. The declination circle is most inconvenient of access, and slow motion in declination can only be effected when the instrument is clamped by a long and inconvenient handle, so that practically clamping in declination was not employed. The slow motion in right ascension is defective, being accomplished in the Dorpat refractor by changing the rate of the clock, and in the Pulkowa refractor by a handle which when used affects very injuriously the rate of the clock for the time being. Struve's skill as an observer was such that he used to complete the bisection on the fixed wire of the micrometer by a pressure of the finger on the side of the tube,—a method of proved efficiency in such hands, but plainly indicative of the want of rigidity in the instrument and of the deficiency of the slow motions (see **Micrometer**, vol. xvi. p. 252). The driving circle is also much too small, so that a very slight mechanical freedom of the screw in the teeth involves a large angular freedom of the telescope in right ascension, whilst its position at the lower end of a too weak polar axis tends to create instability in right ascension from torsion of that axis. Strange to say, the wooden tube has till very recently retained its place in German mountings.

Oxford heliometer.

About 1840 a great advance was made in the right direction by the Repsolds of Hamburg in the equatorial mounting of the Oxford heliometer. The driving circle was greatly increased in diameter, and placed at the upper end of the polar axis, and both the polar axis and the declination axis were made much stronger in proportion to the mass of the

Cooke's equatorial.

instrument they were destined to carry. (A figure of this instrument is given in the Oxford *Observations* for 1850.) About 1850 Thomas Cooke of York began his career as the maker of equatorial telescopes, and gave a new character to the German mounting. Fig. 21 represents a typical equatorial of his design. A strong cast-iron pillar is substituted for Fraunhofer's stand. On the semi-cylindrical top of the pillar rests the cast-iron box AA, which contains at its upper and lower extremities the bearings of the polar axis. Its mode of connection with the pillar permits the inclination of the box to be changed for adjustment of the inclination of the polar axis. The strong cross-head C, supporting the bearings of the declination axis, is of cast-iron, bolted to a flange on the upper pivot of the polar axis. Fraunhofer's cradle and wooden tube are abolished, and in their place is a cast-iron cylindrical tube D, flanged at both ends and also at the point where it is bolted to a corresponding flange on the end of the declination axis, all three flanges being cast in one piece with the central tube; the rest of the tube consists of two slightly tapered brass cylinders bolted by strong flanges to the central tube D. The handle F clamps the arm H to the cross-head C at pleasure, and slow motion in declination is communicated by the handles at E and G. Two circles at K and M are attached to the upper part of the polar axis. To one of these motion is communicated by the tangent screw at M (turned by the clock N) acting on teeth cut at the edge of the circle. The other is a graduated hour circle read by two opposite microscopes, one of which is seen at P. The endless cord hanging down and holding a sliding ring at Q is employed to give slow motion in right ascension, in some instruments by moving the frame of the driving screw in the direction of the axis of the screw, in others by moving differential wheels which accelerate or retard the velocity of rotation of the driving screw without affecting the rate of the clock. The declination circle RR is attached to the farther end of the declination axis and is inconvenient of access. Cooke's stand is admirable for its symmetry and simplicity of design, its just apportioning of strength, and a general rigidity with suitability of means to ends.

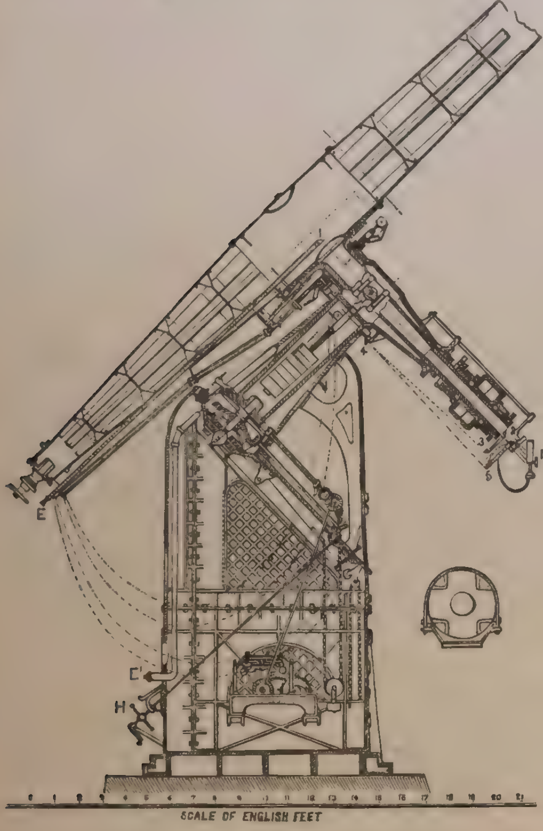

FIG. 22.—Grubb's 27-inch refractor (Vienna).

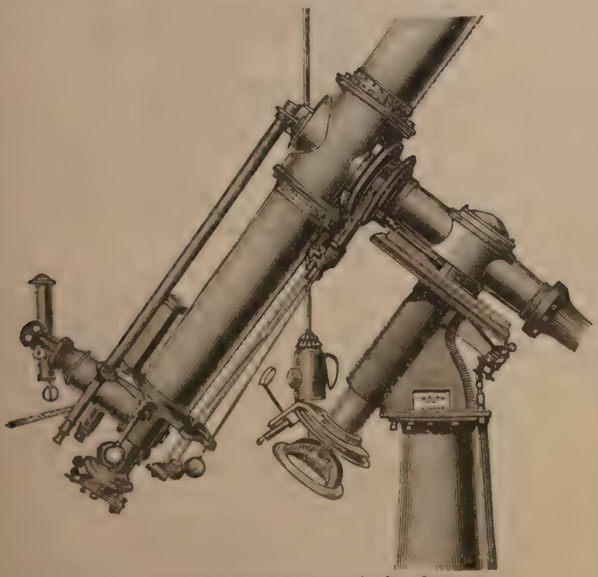

FIG. 23.—Dr. Engelmann's 8-inch refractor.

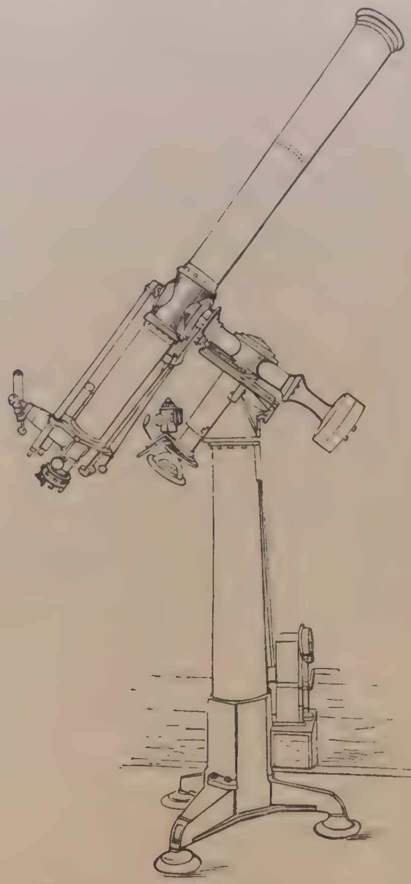

FIG. 24.—Dr. Engelmann's 8-inch refractor.

It is not a little curious that the obvious improvement of transferring the declination circle as well as the declination clamp to the telescope end of the declination axis was so long delayed; we can ascribe the delay only to a desire to retain the declination circle as part of the counter-

Great Vienna telescope.

poise. We believe that the first important equatorials in which the declination axis was read from the eye end were the 15-inch by Grubb and the 6-inch by Cooke, made for the observatory of Lord Crawford (then Lord Lindsay) at Dun Echt (Aberdeenshire) about 1873. The plan is now almost universally adopted. Telescopes of such dimensions can be conveniently directed to any object by the circles without the observer being under the necessity to climb a special ladder. But when much larger instruments are required the hour circle becomes inaccessible from the floor and means have to be devised for reading both circles from the eye end. This was first accomplished by Grubb in the great refractor of 27-inches aperture which he constructed for the Vienna observatory, represented in section in Fig. 22. The observer's eye is applied to the small telescope E, which (by means of prisms numbered 1, 2, 3, 4) views the vernier attached to the cross-head simultaneously with the hour circle attached to the upper end of the polar axis. Light to illuminate the vernier and circle is thrown from the lamp L upon prism 4 by the prisms 6 and 5. Prism 1 is in the axis of the declination circle and always reflects rays along that axis, whatever the position of the telescope may be, whilst the prisms 2, 3, 4, 5, and 6 are attached to the cross-head and therefore preserve their relative positions to each other. Through the eye-piece of the bent[1] telescope E′ another hour circle attached to the lower end of the polar axis can be seen; thus an assistant is able to direct the telescope by a handle at H to any desired hour angle. A slight rotatory motion of the telescope E on its axis enables the vernier of the declination circle to be read through prism 1. The leading features of this fine instrument represent those of all Grubb's large telescopes. The mode of relieving the friction of the declination axis is similar to that employed in the Melbourne telescope and in the account of the Vienna telescope published by Grubb. The end friction of the polar axis is relieved by a ring of conical rollers shown in section beside the principal figure.

From this point we must condense further description into critical remarks on a few typical modern instruments.

Repsolds' small equatorial.

(1) *Telescopes of Moderate Size for Micrometric Research only.*—Fig. 23 shows the mounting of the 8-inch refractor, of 9-feet focal length, at the private observatory of Dr. Engelmann, Leipsic. The object-glass is by Messrs. Clark of Cambridge, Mass., the mounting by the Repsolds of Hamburg. The declination circle reads from the eye end, and four handles for clamping and slow motion in right ascension and declination are situated near the observer's hands. The tube is of sheet steel, light, stiff, and free from tremor. The eye end carries the micrometer with an illuminating apparatus similar to that previously described under **Micrometer**, vol. xvi. p. 258 *sq.*, Figs. 16, 17, 20, and 21. The lamp near the eye end illuminates the field or the wires at pleasure, as well as the position circle of the micrometer and the declination circle; a separate lamp illuminates the hour circle. An excellent feature (see Fig. 24) is the short distance between the eye-piece and the declination axis, so that the observer has to follow the eye end in a comparatively small circle; another good point is the flattening of the cast-iron centre-piece of the tube so that the flange of the declination axis is attached as near to the axis of the telescope tube as is consistent with free passage of the cone of rays from the object-glass. For purposes of micrometric research with the ordinary micrometer this instrument is the most elegant, satisfactory, and useful that we know, as was shown by the exceedingly accurate observations of the minor planets Victoria and Sappho for solar parallax, by Galle's method (see **Parallax**, vol. xviii. p. 254), made by Dr. Engelmann in 1882. The substitution of small incandescent electric lamps for the oil lamps would be an improvement.

Grubb's small equatorial.

(2) *Telescopes of Moderate Size for General Purposes.*—The modern equatorial should for general purposes be capable of carrying spectroscopes of considerable weight, so that the strength of the axis and the rigidity of the instrument generally have to be considerably increased. Grubb has realized our ideas of what such an instrument should be in an equatorial of 6-inches aperture which he has recently made for the royal observatory at the Cape of Good Hope. The principal features are its great strength and rigidity, with special precautions to ensure preservation of the instrumental declination. The observations of Victoria and Sappho in 1882 revealed the great deficiency of most modern equatorials in this respect. That is to say, if a star near the meridian is first made to run along the measuring web of the micrometer, the clockwork then set in action, and the star brought back to the centre of the field by the slow-motion handle in right ascension, it will be found that the perfection of the bisection is no longer preserved. Thus at most observatories the measures of difference of declination when the clockwork was employed were far inferior to those made with the telescope at rest. The reason seems to be that in most equatorials the lower pivot is cylindrical, and enters an ordinary cylindrical bearing which cannot be a perfect fit. Also the cross-head, telescope, counterpoise, etc., generally together overbalance the polar axis about the upper bearing, so that the lower pivot presses upwards in its bearing, and its rotation, under the action of the clock or slow motion coupled with the friction of the surfaces, gives rise to a small rolling freedom which creates the errors in question. In this telescope the lower pivot is of steel, made slightly conical, and carefully ground to fit a long conical bearing, in which it would work very tightly, or even jam, but for spring pressure brought to bear on its lower hardened flat end, which relieves the greater part of the thrust; and the polar axis is accurately balanced about its upper bearing by a weight at the lower end of the polar axis, so that the thrust is exactly in the axis of the cone. The upper pivot (4 inches in diameter) is also of steel, finished with the same care as that of a transit circle, so that the telescope rotates with the precision of a meridian instrument. Unusual rigidity has also been given to the declination clamping arms, and the new slow motion in declination is by far the best yet contrived; it is a recent invention of Grubb's, and is described below in his own words. The eye end, suitable for heavy spectroscopes, etc., is fitted to the butt end of the telescope by bayonet joints and tightening screws, so that it can be exchanged for a micrometric eye end with almost as little trouble as the exchanging of an eye-piece. The illumination of the circles and the micrometer is by electric incandescent lamps. The instrument may be adjusted to any latitude and is probably the most practical and serviceable equatorial made. The subjoined description of the new slow motion in declination is taken from *Proc. R. Dubl. Soc.*, 1886, p. 107.

"The slow motion arrangements usually used in equatorials are of either of two forms, viz., (*a*) an endless screw working into a sector or portion of a toothed circle of long radius, or (*b*) a screw applying or pushing directly against an arm, that arm being kept in contact with the screw by a spiral or some other form of spring having a considerable range of motion. The first (*a*) possesses the disadvantage that, however carefully made, it is impossible it is quite free from 'loss' or 'back lash'; and consequently the position of the telescope is not perfectly determinate in declination, which fault is inconvenient when delicate measures are required. The second (*b*) has practically no 'back lash,' as spring keeps the arm in perfect contact with screw, but it has the disadvantage that, whatever range of motion is required, the spring must be capable of working through the same range; consequently the spring will be much stronger in action at one end of the range than the other, unless it be made very long indeed, in which case its action is uncertain and unpleasant. To remedy these defects the author [Grubb] has devised the following, which possesses the advantages of both: ABCD (Fig. 25) is a portion of the arms attached to telescope, or cradle, on which is planted the block (*b*), forming the bearing of the screw. The nut (*n*) is in the form of a ball working in a socket on the extremity of the clamp-arm EFG. A short stiff spring (S) is attached to this clamp-arm, bearing, not directly against any part of other arm, but against end of a second screw of same pitch as the main screw, the nut of which (*oo*) is toothed on edge, and works into a wheel of equal size (*pp*) on main screw. The point of this second screw, therefore, advances as much in one direction as the frame ABCD is carried in other, according as the milled head is turned; and consequently the point of the screw does not sensibly vary in its position with respect to the clamp-arm EFG. A short stiff spring can therefore be used, and the disadvantage above mentioned disappears."

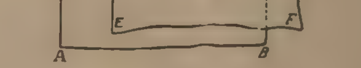

Fig. 25.

---

[1] In the bent telescope refracting prisms are employed at the corners to change the direction of the rays.

This form of slow motion could be applied with advantage to the right ascension also, and probably to the separation of the segments of heliometers.

Large equatorials. Washington telescope.

(3) Of large equatorials we name first the great refractor at Washington of 26-inches aperture and 32½-feet focal length.[1] The mounting appears to be unworthy of the well-known excellence of the object-glass. To illuminate the micrometer an assistant is required to hold a lamp in his hand. No convenient means are provided for illuminating the declination axis; and in order to point the telescope in declination the following elaborate process has to be performed:

> "The instrument is brought into the meridian and set by the observer within a degree by means of coarse divisions painted on the edge of the declination circle. These divisions are rendered visible by lighting one or two of the gas burners of the dome, and viewed by the astronomer with an opera-glass. Then an assistant mounts by a ladder to a high platform and holds a gas lamp near the vernier, and the fine setting is accomplished by the observer seated in the observing chair, the declination clamp and slow-motion screw being convenient to his hand."—(*Washington Observations*, 1874, Appendix I., p. 33).

The polar and declination axes are of steel, only 7 inches in diameter at the thickest point, and the driving arc, which is far too small, is placed at the lower end of this slender axis. There must thus be considerable liability to tremor in right ascension. However well the instrument may act in specially practiced hands with an excellent Clark's micrometer (art. MICROMETER, vol. xvi. p. 254), the instrument must be considered wanting in the rigidity and convenience which a modern equatorial should possess. In his official report on the instruments of European observatories Newcomb defends the want of solidity and convenience of this instrument as compared with the Vienna telescope, because its smaller axes (notwithstanding Grubb's anti-friction arrangements) permit it to turn more easily and the mounting to be of far simpler design. But at the time of Newcomb's visit the Vienna telescope had not been brought into work, and cannot have been in proper working order if the motion in declination was so stiff as he describes it; at least when the present writer tested the instrument in Dublin that motion was surprisingly easy.

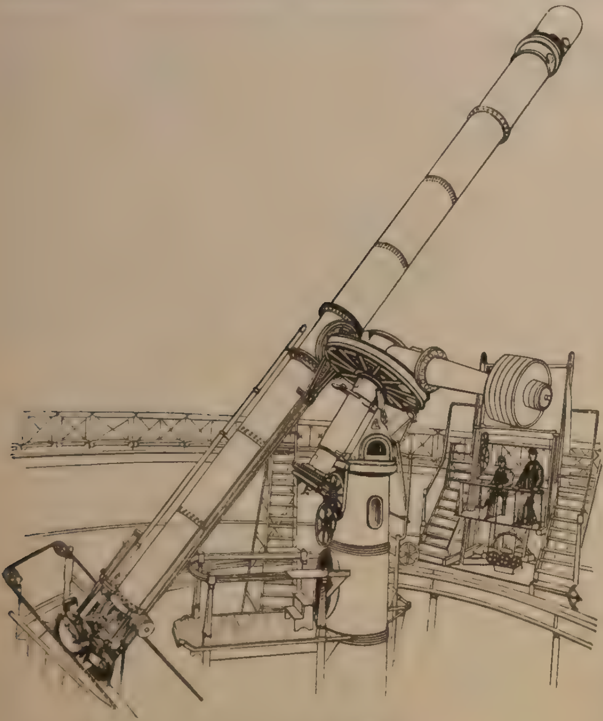

FIG. 26.—Pulkowa refractor.

Pulkowa refractor.

The great Pulkowa refractor (Fig. 26) erected in 1885 is of 30-inches aperture and 45-feet focal length. The object-glass is by Clark, the mounting by the Repsolds. The tube is cylindrical, of riveted steel plate, graduated in thickness from the centre to its extremities, and bolted by very powerful flanges to a strong short cast-iron central tube, in which, as in Dr. Englemann's telescope (Fig. 23), the attachment to the flange of the declination axis is placed as close as it can be to the axis of the tube without interfering with rays converging from the object-glass to any point in the field of view. A new feature in this instrument is the platform at the lower end of the polar axis, where an assistant can view the hour circle by one eye-piece and the declination circle by another (looking up the perforated polar axis), and where he can also set the telescope to any hour angle by one wheel, or to any declination by a second, with the greatest ease. The observer at the eye end can also read off the hour and declination circles and communicate quick or slow motions to the telescope both in right ascension and declination by conveniently placed handles. The eye end presents an appearance too complicated to be figured here; it has a micrometer and its illumination for the position circle, a micrometer head, and a bright or dark field,[2] clamps in right ascension and declination and quick and slow motion in the same, a finder, microscopes for reading the hour and declination circles, an illuminated dial showing sidereal time and driven by a galvanic current from the sidereal clock, and counter weights which can be removed when a spectroscope or other heavy appliance is added. All these, although making up an apparently complicated apparatus, are conveniently arranged and are all necessary for the quick and easy working of so large an instrument. We have the authority of Otto Struve for stating that in practice they are all that can be desired. There is in this instrument a remarkably elegant method of relieving the friction of the polar axis. Let AA (Fig. 27) be a section of the polar axis; it is then easy to adjust the weight P of the circles, etc., attached to its lower end so that the centre of gravity X of the whole moving parts of the instrument shall be in the vertical (VV) of a line passing through the apex of the hollowed flange *pq* at *q*, which flange forms part of the polar axis. If now a wheel W is forced up against *q* with a pressure equal to the weight of the moving part of the instrument, the whole weight of the moving part would rest upon W in unstable equilibrium; or if a pressure R, less than W, is employed, we have the end friction on the lower bearing removed to an extent = R sin ϕ, and the friction on the bearings of the upper pivot removed to the extent of F cos ϕ,—where ϕ is the latitude of the place. The wheel W is therefore mounted on a guiding rod, which is forced upwards by suitable levers and weights, and this relief of pressure is precisely proportional to the pressure on the respective bearings. The Repsolds find it unnecessary to relieve the friction of the declination axis.

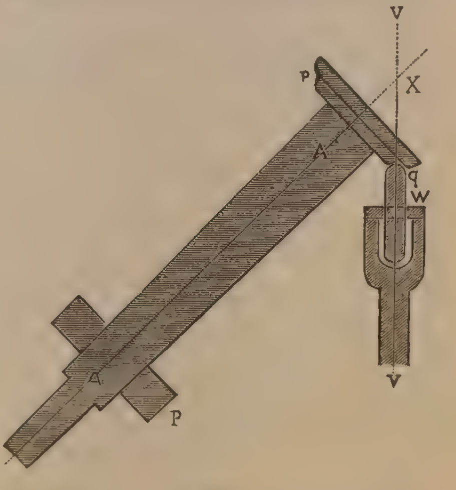

FIG. 27.

Fig. 28 shows the equatorial mounting which Grubb designed for the great object-glass of 36-inches aperture that Messrs. Clark have completed for the Lick trustees, and which may be supposed to express Grubb's

[1] Described and figured in the *Washington Observations*, 1874, App. I.

[2] There is also an elegant arrangement for printing on a ribbon of paper, by pressure of the finger, the readings of the number of revolutions and fractions of a revolution of the head at each observation, the ribbon being automatically moved forward for another record after each observation.

latest ideas as to the mounting for a very large telescope.[1] The Repsolds have a large driving circle at the upper end of the polar axis, thus avoiding torsion of the polar axis at the expense of greatly increased length of the cross-head. Grubb by employing a driving arc gets the telescope much closer to the polar axis with an increased radius for driving, and he makes the polar axis a very large hollow steel or cast-iron cylinder in which torsion is insensible. Both Grubb and the Repsolds seem to think that for the tube of the telescope all necessary rigidity can be attained with cylindrical tubes of riveted steel, the thickness of the successive sheets of which diminish from the centre-piece outwards without making the extremities cone-shaped.

Grubb's design for 36 inch refractor.

In these very large telescopes the arrangements for giving access to the eye end and for following its diurnal motion have hitherto proved a source of difficulty. The travelling stages of the new Pulkowa telescope are the most manageable and practical that have yet been contrived, but even they leave much to be desired. For energetic work the standing position is best, provided that the eye-piece is situated at the precise height above the stage which is most convenient for the observer, and that the altitude of the observed object is not greater than 60°. For altitudes above 60° a small chair with a back, the top of which is stuffed for the head to rest upon, is the best seat, provided that the observer's eye can be kept at the height of the eye-piece. Accordingly Grubb has suggested the following plan for the observatory at Mount Hamilton, California, which is to cover the Lick telescope. The whole floor, 70 feet in diameter, is to be raised or lowered by water-power under control of the observer by means of electric keys, which act on a secondary piece of mechanism, that in turn works the valves and reversing gear of the water-engines.[2] Other water-engines, similarly connected with keys at the observer's hands, rotate the dome and perform the quick motions in right ascension and declination.[3] By this arrangement a large instrument can be worked with perfect facility and comfort. There is only one other plan, that of suspending the observer's chair to the eye end, so that his eye is near the centre of motion of the chair. This is quite practicable for a 36-inch telescope, and one observer, with the necessary guiding keys at hand, could easily work a telescope and dome of the largest dimensions as quickly and with more ease than he could one of 10 or 12 inches aperture. Probably a nervous astronomer would prefer a solid floor to work upon, as in Grubb's proposal; in the latter case the quickest working can only be accomplished by two persons, one seated on the platform at the foot of the polar axis and doing the rough setting in right ascension and declination, the other meanwhile adjusting the height of the floor and the azimuth of the dome opening.

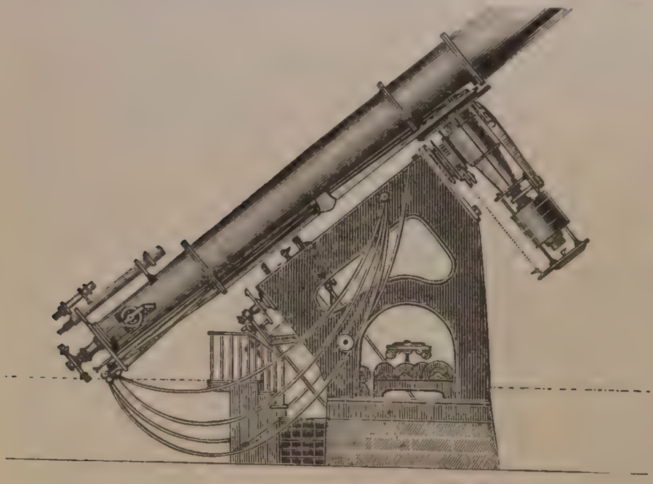

FIG. 28.—Grubb's mounting for the Lick object-glass.

Proposed facilities for using large telescopes.

In very large equatorials there must be in existing methods considerable inconvenience from the extended width of the apparatus at the eye end. Were we called upon to design a great refractor we should abolish all such apparatus and provide the observer with a few conveniently placed small handles or keys for electrical connections, and we should perform all motions of the telescope whatsoever by electromotors. There is no form of energy so convenient for the astronomer. It provides by incandescent lamps the most suitable light for his purpose, perfectly constant, giving off little heat, and unaffected by wind; and such a light can be placed where required without the aid of reflectors or any complicated apparatus, and its intensity can be regulated with ease and precision by changing the resistance of the conductors. Moreover the electromotors can be as powerful or as delicate as we please, and can be placed in the most convenient or suitable positions. The energy of a 5-horse-power steam-engine working for ten hours can be stored in accumulators of no inconvenient dimensions ready for use as required during a whole week or even a month, and can be brought into action in force equivalent to several horse-power to raise or lower the floor or turn the dome, or to perform slow motions requiring no greater energy than that exercised by the finger and thumb, or to illuminate a lamp of $\frac{1}{2}$ or $\frac{1}{4}$ candle-power. There would be no limit to the rigidity which could be given to such a telescope, as great ease of motion would not have to be considered, and we should abolish all complicated anti-friction apparatus for the declination axis, retaining it only for the polar axis to save wear in the teeth of the driving arc. Finally, instead of making the finder a short telescope attached to the eye end of the instrument, we should give it a focal length equal to that of the great object-glass, attaching the cell of its object-glass rigidly to the cell of the large object-glass and its eye end to the butt end of the main telescope, in order to secure the utmost rigidity in the relations of the axes of the two telescopes. Such a finder would correspond in efficiency to that of the Henry photographic telescope and would be available as a guiding telescope in photographic work, or for keeping a star exactly on the slit of a spectroscope.

Type D.

Lassell's mounting.

The first important instruments of type D were Mr. Lassell's reflectors, the largest of which, and the last, is represented in Fig. 29. The polar axis is sufficiently rigid, but the long and comparatively slender forks which carry the pivots of the central cradle are elements of instability, especially when the instrument is directed to an object of considerable hour angle. There is practical confession of this instability in the cross-bracing which connects the two forks, and which must be removed if the telescope is pointed to an object between the zenith and the elevated pole.

Common's mounting.

The best example of type D is the reflecting telescope of 36-inches aperture designed by Mr. A. A. Common, with which his exquisite photographs of nebulæ, etc., were made. The principal preliminary conditions which he laid down as necessary were the following:[4] (1) no tube properly so called, to avoid air-currents in the tube; (2) no mass of metal either below or at the side of the line joining the large and small mirrors, to avoid currents from possible difference of temperature between the mass of metal and the surrounding air; (3) an equatorial mounting capable of direction to any part of the visible heavens and of continued observation past the meridian without reversal; (4) an efficient means of supporting the mirror without flexure; (5) driving clock; circles to find or identify an object, and motions taken to eye end; (6) a mounting which will give the greatest amount of steadiness with the least amount of friction. Fig. 30 is a section of the instrument in the plane of the meridian. DD₁ is a cast-iron hollow cylinder, accurately bored out, attached to a strong base block. D₂ is a cover bolted on the bottom of this cylinder, in the centre of which is a tapering steel pin D₃, which enters a corresponding hole in the bottom of the polar axis E, and serves as the lower pivot of the polar axis. The cylindrical part of the polar axis is accurately turned to a diameter one-eighth of an inch less than the outer cylinder, and the otherwise severe friction on the pin D₃ is relieved by filling in the space between D and E with mercury, so far as sufficient nearly to float the whole moving part of the telescope. The upper elbow-shaped part of the polar axis E₂ is flanged and bolted to the lower part. In the section at right angles to that exhibited in Fig. 30 this elbow-shaped part is T-shaped, and the cross of the T is bored to receive the declination axis; and, as the elbow puts the polar axis considerably out of balance, the T-shaped head is carried forward of the axial line about 1¼ inches, so that the whole weight of the telescope above just restores the balance. Two heavy weights X, X counterpoise the eye end F with the four braced tubes T, T which support it. B is the declination circle. It is impossible to describe this fine instrument adequately within our limits; we mention as specially worthy of study the method of supporting the mirror and the eminently ingenious and practical form of the observatory, and refer the reader to Common's illustrated account of the instrument in *Mem. R.A.S.*, vol. xlvi. pp. 173–182.

---

[1] [The first maker of achromatic lenses in America was Alvan Clark of Mass. (1804-1887.)

He was in early life a portrait painter. About 1844 he began making small telescopes and inventing improvements so highly appreciated by astronomers, that, in company with his sons, he soon gained world-wide fame.

Among the lenses famous not only for size, but accuracy, from the shop of Alvan Clark and Sons, are those for the Naval observatory at Washington and the University of Virginia, each 26 inches in diameter; for the Imperial observatory at St. Petersburg, 30 inches; and for the Lick observatory on Mount Hamilton, California, 36 inches in diameter for the clear aperture.

This is the largest object-glass in the world, and will show the moon as it would appear to the naked eye at about 200 miles from the earth.—AM. ED.]

[2] [The elevating floor is 61½ feet in diameter, weighing 50,000 pounds, and is moved up and down through a space of 16 feet. (See *Scientific American*, March 17, 1888.)

The Lick telescope constructed at a cost of $700,000, pursuant to a bequest of James Lick, a native of Pennsylvania but long a resident of California, was first directed to the sky on the night of 3d January, 1888.

The donor died, October, 1876, aged 78 years, and his body was interred under the base of the great telescope.—AM. ED.]

[3] A woodcut showing these arrangements appeared in the *Engineer*, 9th July, 1886.

[4] *Monthly Notices R.A.S.*, vol. xxxix. p. 384.

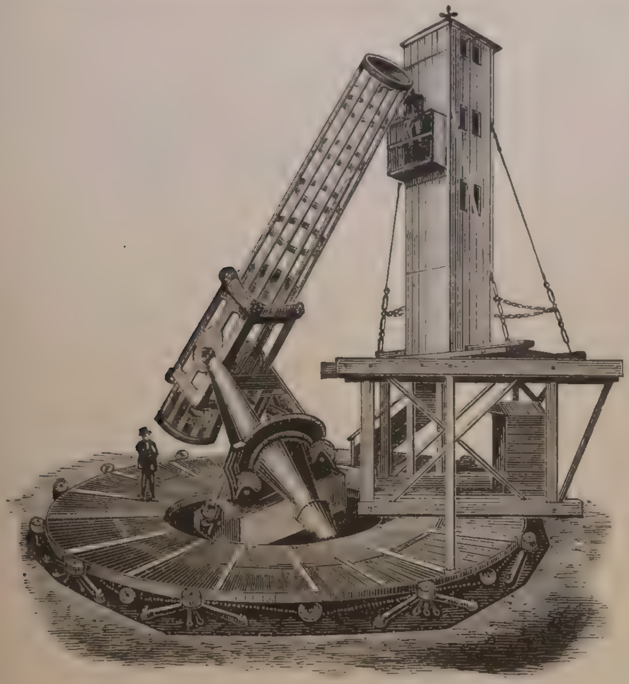

FIG. 29.—Lassell's reflector.

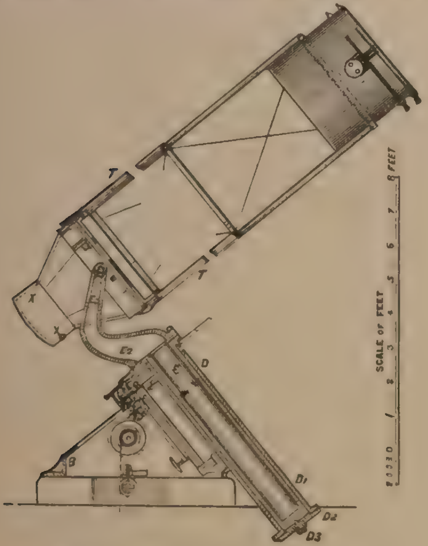

FIG. 30.—Common's reflecting telescope.

Rosse's 3-foot mounting.

There is also an admirable mounting of type D designed by Lord Rosse for his 3-foot reflector at Birr Castle, described by him in *Phil. Trans.*, vol. clxxi. p. 153. The instrument is planned on the broad lines of Lassell's telescope (Fig. 29), but the badly planned and weak fork of the latter is replaced by a thoroughly rigid bent fork made of boiler plate a quarter of an inch thick, firmly riveted to angle iron of 2¼ × 2¼ × $\frac{5}{16}$ inch scantling along each angle, the whole, as we have proved by trial, being exceedingly rigid. It would be an improvement to adopt Mr. Common's plan of putting the declination axis a little out of the line of prolongation of the polar axis, and thus dispense with the counter-weight; and we should prefer hollow steel tubes with push and pull bracing rather than the angle iron rods and bracing which form the tube.

Type E.

Grubb's siderostatic telescope.

In the *Proceedings* of the Royal Dublin Society (vol. ii. p. 362), Grubb describes a "siderostatic telescope," which forms a good elementary example of type E. In Fig. 31 TT is the tube of a telescope of 4-inches aperture, which is mounted to rotate about its axis, the latter forming the polar axis. MM is a plane mirror reflecting rays from a star S to the object-glass, so that its image can be viewed from the eye-piece at E. The star is retained in the field by the clock C. Stars of different declination can be viewed by rotating the mirror on its axis G, and in different hour angles by rotating the tube upon its axis. The instrument in European latitudes cannot command a view of the heavens between the elevated pole and the zenith unless the distance OG is made exceedingly great; even then only a limited range beyond

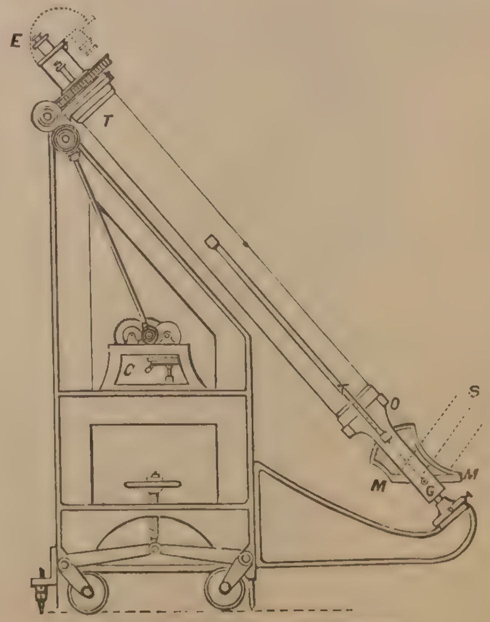

FIG. 31.—Grubb's siderostatic telescope.

the zenith is possible. The instrument is primarily intended for solar spectroscopy, and thus these drawbacks do not apply. The resulting advantage is that the observer may be in complete darkness and his observations are not interrupted by change of position.

Loewy's equatorial coudé.

In *Comptes Rendus* for the year 1883, vol. xcvi. pp. 735–741, M. Loewy gives an account of an instrument which he calls an "equatorial coudé," designed (1) to attain greater stability and so to measure larger angles than is generally possible with the ordinary equatorial; (2) to enable a single astronomer to point the telescope and make observations in any part of the sky without changing his position; (3) to abolish the usual expensive dome, and to substitute a covered shed on wheels (which can be run back at pleasure), leaving the telescope in the open air, the observer alone being sheltered. These conditions are fulfilled in the manner shown in Fig. 32. EP is the polar axis, rotating on bearings at E and P. The object-glass is at O, the eye-piece at E. There is a plane mirror at M, which reflects rays converging from the object-glass to the eye-piece at E. A second mirror N, placed at 45° to the optical axis of the object-glass, reflects rays from a star at the pole; but by rotating the box which contains this mirror on the axis of its supporting tube T a star of any declination can be observed, and by combining this motion with rotation of the polar axis the astronomer seated at E is able to view any object whatever in the visible heavens, except those situated between 10^h and 12^h hour angle. An hour circle attached to EP and a declination circle attached to the box containing the mirror N, both of which can be read or set from E, complete the essentials of the instrument. Its mechanical details present no great difficulty, and are most conveniently arranged. But we entertain grave doubts as to the practical value of the instrument, not on mechanical, but on optical grounds. There must be a certain loss of light from two additional reflections; but that could be tolerated for the sake of other advantages, provided that the mirrors could be made sufficiently perfect optical planes. A few years ago it was very difficult to obtain an optically perfect plane 6 inches in diameter, and having obtained it there remained the further difficulty of mounting it so that in all positions it should be free from flexure. By making the mirrors of silvered glass, one-fourth of their diameter in thickness, MM. Henry have not only succeeded in mounting them with all necessary rigidity free from flexure, but have given them optically true plane surfaces, notwithstanding their large diameters, viz., 11 and 15.7 inches. The present writer tested the equatorial coudé on double stars at the Paris observatory in 1884, and his last doubts as to the practical value of the instrument were dispelled. He has never seen more perfect optical definition in any of the many telescopes he has employed, and certainly never measured a celestial object in such favorable conditions of physical comfort. The easy position of the observer, the convenient position of the handles for quick and slow motion, and the absolute rigidity of the mounting, leave little to be desired. In future instruments the object-glass will be placed outside the mirror N, so that both the silvered mirrors will be protected from exposure to the outer air, and probably will retain the brilliancy of their surfaces for a long period.

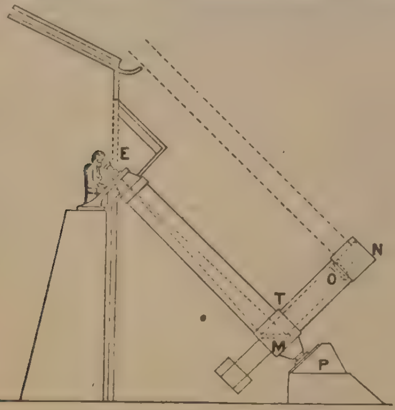

FIG. 32.—Loewy's coudé equatorial.

Adjustment of the Equatorial.

Adjustment of equatorial.

Let us take the usual case, that of an equatorial of type C. (1) By means of an azimuth compass, or, better, by the shadow of a plumb line at apparent noon, lay down a meridian line on the upper surface of the stone pier, or other foundation, previously built for the instrument. (2) Employ this meridian line to set up the instrument and with it the polar axis approximately in the azimuth of the meridian, which can be tested by stretching a wire through the centres of the bearings of the polar axis, and dropping a plumb line from the extremities of the wire upon the meridian line. If this is carefully done when the azimuth adjustment is near the middle of its range all desirable accuracy in this preliminary desideratum will be secured. (3) Place the polar axis approximately at the altitude of the pole. This is very easily done for an instrument in which the polar axis is cylindrical or is encased in a box with an upper side parallel to that axis (as in Grubb's or Cooke's equatorials). Prepare a right-angled triangle of wood of which the acute angles represent the latitude and co-latitude of the place. Lay the hypothenuse of this triangle upon the line of the instrument parallel to the polar axis (or the wire of operation 2) with the angle equal to the co-latitude next to the elevated pole, and change the inclination of the polar axis till a mason's level placed on the side of the triangle opposite to the angle of the latitude shows the side in question to be horizontal. (4) Adjust the movable micrometer web to coincidence with the axis of the position circle by bisecting the image of a distant object and reading the number of revolutions or fractions of a revolution at two different readings of the position circle 180° apart. The mean of these two readings is the reading for coincidence with the axis of the position circle. Set the micrometer to this mean. (5) Adjust the polar axis more exactly to the required altitude as follows. Point the telescope to a well-known star not far from the equator and near the meridian, and turn the position circle so that the image of the star by the diurnal motion runs along the web. Read the declination circle. Now reverse the telescope to the other side of the polar axis and bisect the same star again, and again read the declination circle. The mean of the two readings is the star's instrumental apparent declination; the difference of the two readings is twice the index error. To eliminate this latter it is only necessary to shift the vernier of the declination circle by the screws provided for the purpose, without unclamping in declination, till the circle reads the star's instrumental apparent declination. This being done, select another star near the meridian and compute its apparent declination (allowing for refraction). Set the telescope to this computed reading and clamp in declination; then cause an assistant to change the altitude of the polar axis (by the screw for the purpose) till the star is bisected by the micrometer wire. (6) Select any convenient known star about six hours from the meridian; compute its apparent declination (allowing for refraction); and set the telescope to this reading in declination. Cause the assistant to turn the slow motion in azimuth till the image of the star is bisected by the micrometer web. (7) Repeat operation 5 and make final corrections if necessary. (8) Repeat operation 6 with stars both east and west of the meridian, and readjust azimuth if necessary. (9) Turn the position circle of the micrometer 90°; place the declination axis nearly horizontal; clamp the telescope in right ascension; and observe the time of transit of a known star across the web of the micrometer. Compute the true hour angle of the star from the known error of the micrometer and the star's right ascension, and set the vernier so that the hour circle shall read the computed hour angle. By these means, with a previously prepared programme, the writer has frequently completely adjusted an equatorial in less than an hour, so far as operations 4 to 9 were concerned.

There still remain two instrumental errors of the stand. (1) The line joining the optical centre of the lens with the axis of rotation of the position circle may not be at right angles to the declination axis. (2) The declination axis may not be at right angles to the polar axis. In modern equatorials it is usual to leave these adjustments to the maker, as to leave them to the astronomer would be incompatible with the greatest stability of the instrument. In a good instrument these errors will certainly be extremely small and have no influence on its efficiency for practical purposes. The methods for determining their amount are given in most works on practical astronomy.[1]

There remain two important optical adjustments which must be very carefully attended to, viz., the centring of the lenses of the object-glass relative to each other and the centring of the axis of the object-glass relative to that of the eye-piece. The former consists in placing the lenses of the object-glass so that the centres of curvature of their surfaces shall lie in one straight line, which line is the axis of the object-glass. This operation is so delicate and requires such special experience and skill that it should be left to the maker of the object-glass. An elegant method of testing this adjustment was given by Wollaston in *Phil. Trans.*, 1822, p. 32. If the object-glass itself is perfectly centred, the test of the centring of its axis with that of the eye-piece is very easy: are the diffraction rings which surround the image of a bright star shown as in Fig. 33, or is there flare, that is, are the rings extended on one side as in Fig. 34? If the latter is the case, that side of the object-glass towards which the flare is directed is too far from the eye-piece, and should be brought towards it by the appropriate screws or other means provided by the maker. In a good object-glass perfectly centred, on a night of steady definition, a bright star in focus should appear as in Fig. 33.

---

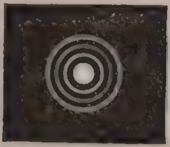

FIG. 33.

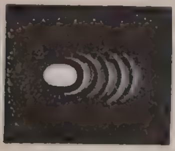

FIG. 34.

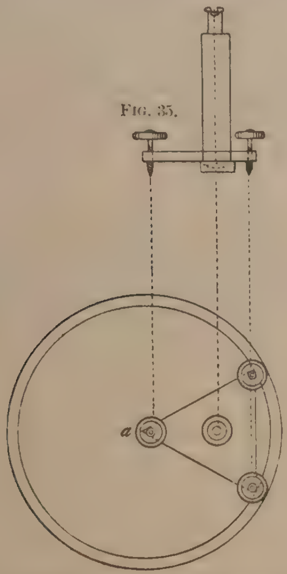
FIG. 35.



FIGS. 35, 36.—Apparatus for adjustment of centring in a small telescope.

A useful apparatus for the adjustment of centring is a small telescope (Fig. 35) whose axis is in the centre of and at right angles to a flat piece of brass in the shape of an equilateral triangle fitted with screws at the three angles. To use this instrument, place the points of the screws on the object-glass as in Fig. 36, so that two angles of the triangle are in contact with the inner edge of the cell of the object-glass, and adjust the screw *a* so that the cross-wires in the common focus of the object-glass and eye-piece of the small telescope coincide with the image of the cross-wires of the micrometer of the telescope which mark the axis of rotation of the position circle. Now, keeping the same angles of the brass triangle in contact with the cell, move the small centring telescope round the circumference of the object-glass and note where there is the greatest departure from coincidence. Correct this departure half by the screw *a* of the small centring telescope and half by the centring screws of the object-glass. The adjustment is perfect when the centring telescope can be moved round the whole periphery of the object-glass in the above manner whilst its cross-wires continue to bisect the cross-wires of the micrometer of the telescope. If after this adjustment has been perfected the diffraction rings are still not circular round the images of stars, the fault is in the centring of the lenses of the object-glass with respect to each other, and the object-glass should be sent to the maker for rectification.

Driving Clock.

Driving clock.

The means employed to cause an equatorial telescope to follow the diurnal motion of a star obviously must not resemble the intermittent motion of an ordinary clock. Numerous devices have been contrived for producing uniform motion. But the limits of this article will only allow us to refer briefly to a few of those most commonly in use. Fig. 37 represents Fraunhofer's governor. On its axis C is a pinion driven by a train of wheels. The axis carries an arm BB, at the extremities of which, attached by springs *f*, *f′*, are the weights D, D′. When these weights acquire a certain velocity of rotation the centrifugal force is sufficient to cause the weights to fly out and rub against the inside of the cylinder AA, and their velocity is checked. Instead of a cylinder, the balls may rub against the inside of a hollow cone, and by raising or lowering the axis C the contact of the weights with the cone may be made to take place when the balls have slightly greater or less velocity, and thus the rate of the clock is regulated. A much better arrangement is a modification of Watt's governor, employed by Grubb and Cooke. The governor balls *g*, *g* (Fig. 38) repose on the points *h*, *h* of the arm KK till they reach their normal velocity, when they fly outwards and bring the point S (tipped with leather) into contact with the friction plate *p*. These clocks are simple in construction and act very well. Newcomb in the Washington equatorial has employed a long suspended conical pendulum; when this pendulum in the least exceeds its normal velocity (that is, its normal departure from the vertical) it establishes an electrical contact which brings friction to bear, and thus reduces the power applied to the pendulum. There is occasional tendency to elliptical motion, and the clock is otherwise troublesome. In the Repsolds' driving clock of the 30-inch Pulkowa refractor the conical pendulum is reversed, being a heavy weight at the top of a vertical steel rod, kept in conical rotation by a pin at its upper end, which enters a slot in a revolving arm. The rod is in fact a spring of such a form as to cause the revolutions to be nearly or perfectly isochronous whatever the angle of the cone of motion; the clock is therefore, within limits, independent of the power applied to it or the force to be overcome.

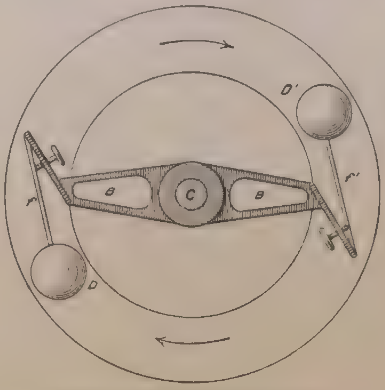


FIG. 37.—Fraunhofer's governor.

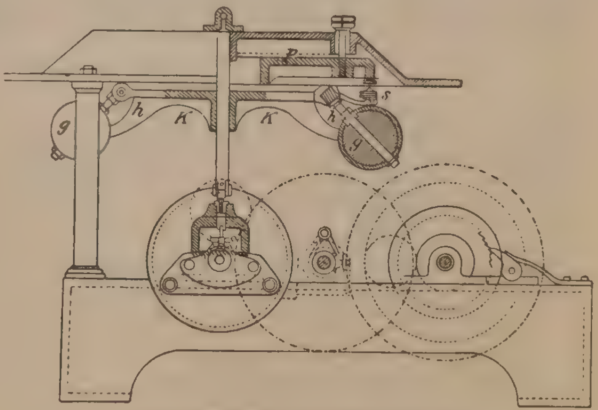

FIG. 38.—Modification of Watt's governor.

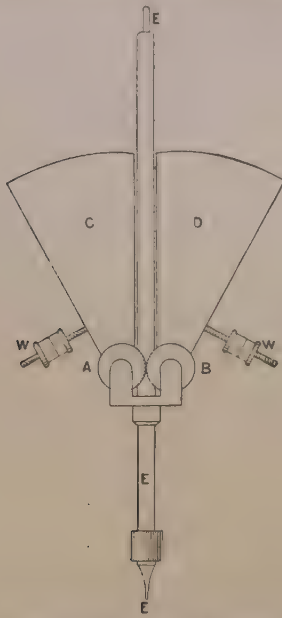

FIG. 39.—Hilger's modification of Foucault's air-fan.

Many forms of air-fans have been suggested; probably the best is the modification of Foucault's proposed by Hilger (see *Monthly Notices R. A. S.*, vol. xlvi. p. 155), which is shown in Fig. 39. E is the axis of rotation; C and D are fans that are pulled towards the spindle E by chronometer springs in the boxes A and B. The fans fly out symmetrically when the velocity exceeds 25 or 30 revolutions per second; the increased resistance of the air thus produced checks the velocity of rotation. By means of the small weights W, W attached to arms on the fans Hilger states that it is possible to adjust this governor so that it shall even lose by an increase of the driving weight.

For the most refined work none of these governors can be said to be perfect; none would be even tolerable as a clock for astronomical time-keeping purposes. It is possible that the elaborate Greenwich driving clock may give better results, but its construction is too complicated to be frequently repeated (see, for a description of it, the Greenwich *Observations* for 1868). The only way in which nearly perfect uniform motion can be realized is to control it in some way from a swinging pendulum. This is done in Bond's spring governor[1] and by Grubb, the latter employing the arm of a remontoir train connected with a dead-beat escapement to bring friction to bear on a revolving plate connected with the axis of his governor (see Fig. 38). The best existing driving clock is probably that at Lord Crawford's observatory at Dun Echt.[2] An account of its performance is given by Dr. Copeland in *Vierteljahrsschr. astron. Gesellsch.*, 16 Jahrg., p. 305. In this clock gain of a hundredth of a second, or even less, introduces increased friction on the revolving disk during the next second, or until the gain has been corrected. A still more perfect clock could probably be made on a similar plan by abolishing the clock weight and making the origin of power an electromotor, the current being cut off in a way similar to that in the Dun Echt clock if the clock of continuous motion gets in advance of the ordinary clock.

For information on clockwork of equatorials and telescope mountings generally, see Konkoly's *Practische Anleitung zur Anstellung astron. Beobachtungen.* (D. GI.)

TELESPHORUS, bishop of Rome from about 128 till about 137, succeeded Sixtus I. and was followed by Hyginus. Eusebius in his *History* gives the date of the martyrdom of Telesphorus as the first year of Antoninus Pius (138) and in his *Chronicle* as the eighteenth year of Hadrian (135).

TELFORD, THOMAS (1757–1834), civil engineer, was the son of a shepherd in Eskdale, Dumfriesshire, and was born in the valley of the Megget, 9th August, 1757. From early childhood he was employed as a herd, occasionally attending the parish school of Westerkirk, where his quickness and diligence helped to make up for his lack of opportunity. On being apprenticed, at the age of fifteen, to a stone mason at Langholm, he found leisure not only to gain an acquaintance with Latin, French, and German, but to gratify his literary tastes by a wide variety of reading. In his early manhood he was much given to the writing of verse: a poem of some length on Eskdale appeared in 1784 in the *Poetical Museum*, published at Hawick; under the signature of "Eskdale Tam" he contributed verses to Ruddiman's *Weekly Magazine*; and he addressed an epistle in rhyme to Burns, which was published in Currie's *Life* of the poet. But these poetical effusions were of comparatively little value. In 1780 Telford went to Edinburgh, where he was employed in the erection of houses in the "new" town, and occupied much of his spare time in learning architectural drawing. Two years later he proceeded to London, finding employment in the erection of Somerset House. Having in 1784 superintended the erection of a house for the commissioner at Portsmouth dockyard, he next repaired the castle of Sir W. Pulteney, member for Shrewsbury, who conceived such a high opinion of his talents that he got him made surveyor of public works for the county of Salop. His earliest bridge was that across the Severn at Montford, finished in 1792. In the following year he was appointed engineer of the Ellesmere Canal, which led to his being employed for the chief canals subsequently constructed in Great Britain, including the Caledonian (1804), the Gloucester and Berkeley (1818), the Grand Trunk (1822), the Macclesfield (1824), and the Birmingham and Liverpool Junction (1825). He was consulted in 1806 by the king of Sweden regarding the construction of the Gotha Canal between Lake Wener and the Baltic, and, his plans having been adopted, he visited the country in 1810 to superintend some of the more important excavations. In 1803 he had been appointed engineer for the construction of 920 miles of roads in the Highlands of Scotland, a great part through very difficult country. Of the numerous bridges built in this line of roads mention may be specially made of that across the Tay at Dunkeld. Subsequently he perfected the road communication between London and Scotland and the northern towns of England. An undertaking of equal magnitude and importance with that in the Highlands of Scotland was a system of roads through the more inaccessible parts of Wales, which involved the erection of the magnificent suspension bridge across the Menai Straits, begun in 1820, and the Conway bridge, begun in 1822. For the Austrian Government Telford built the Polish road from Warsaw to Brest. While the fame of Telford rests chiefly on his road and canal engineering, and the erection of the numerous bridges and aqueducts which this involved, he also did good work in harbor construction. In 1790 he was employed by the British Fishery Society to inspect the harbors on the northeast coast of Scotland; and, besides constructing the important fishing harbor at Pulteneytown, Wick, he greatly improved those at the other principal fishing stations. His important works of this kind were, however, his improvement of the harbors at Aberdeen and Dundee, and the construction of the St. Katherine's docks at London. In 1828–30 he drained the north level of the eastern Fen district, an area of 48,000 acres. The erection of the Dean Bridge, Edinburgh, and of the Broomielaw

[2] *Monthly Notices R. A. S.*, November, 1873.

Bridge, Glasgow, and the improvement (1833–34) of Dover harbor were the principal achievements of his later years. He died on 2d September, 1834, and was buried in Westminster Abbey.

Telford was never married. For twenty-one years he lived at the Salopian coffee house, afterwards the Ship Hotel, Charing Cross. He was a fellow of the Royal Societies of London and of Edinburgh, and was annually elected president of the Institution of Civil Engineers from its commencement. He received the Swedish order of knighthood "of Gustavus Vasa."

See Telford's *Memoirs*, written by himself and edited by John Rickman (1838); also Smiles's *Lives of the Engineers.*

TELL. The story of William Tell's skill in shooting at and striking the apple which had been placed on the head of his little son by order of Gessler, the tyrannical Austrian bailiff of Uri, is so closely bound up with the legendary history of the origin of the Swiss Confederation that they must be considered together. Both appear first in the 15th century, probably as results of the war for the Toggenburg inheritance (1436–50); for the intense hatred of Austria, greatly increased by her support of the claims of Zurich, favored the circulation of stories which assumed that Swiss freedom was of immemorial antiquity, while, as the war was largely a struggle between the civic and rural elements in the Confederation, the notion that the (rural) Schwyzers were of Scandinavian descent at once separated them from and raised them above the German inhabitants of the towns.

The Tell story is first found in a ballad the first nine stanzas of which (containing the story) were certainly written before 1474. There is no mention made of the names of the bailiff or of his master, or of the hat placed on a pole. Tell is called "the first Confederate," and his feat is treated as the real and only reason why the Confederation was formed and the tyrants driven out of the land. It is probably to this ballad that Melchior Russ of Lucerne (who began his *Chronicle* in 1482) refers when in his account (from Justinger) of the evil deeds of the bailiffs in the Forest districts, he excuses himself from giving the story. He goes on to narrate how Tell, irritated by his treatment, stirred up his friends against the governor, who seized and bound him and was conveying him by boat to his castle on the Lake of Lucerne, when a storm arose, and Tell, by reason of his great bodily strength, was, after being unbound, given charge of the rudder on his promise to bring the boat safely to land. He steers it towards a shelf of rock, called in Russ's time Tell's Platte, springs on shore, shoots the bailiff dead with his crossbow, and goes back to Uri, where he stirs up the great strife which ended in the battle of Morgarten. In these two accounts, which form the basis of the Uri version of the origin of the Confederation, it is Tell and Tell only who is the actor and the leader. We first hear of the cruelties of Austrian bailiffs in the Forest districts in the *Bernese Chronicle* of Conrad Justinger (1420). No names or details are given, and the dates are different in the two recensions of the *Chronicle* as "olden days before Bern was founded" (*i.e.*, before 1191) and 1260. Several details, but only one name, are added in the *De Nobilitate et Rusticitate Dialogus* (cap. 33) of Felix Hemmerlin, a canon of Zurich, who wrote it after 1451 and before 1454; in this last year he was imprisoned by the Schwyzers, whom he had repeatedly insulted and attacked in his books. According to him, the men of Schwyz and of Unterwalden were the first to rise, those of Uri following suit much later. But neither Justinger nor Hemmerlin makes any allusion to Tell or his feat.

The Tell story and the "atrocities" story are first found combined in a MS. known as the *White Book of Sarnen*. They are contained in a short chronicle written between 1467 and 1476, probably about 1470, and based on oral tradition. Many details are given of the oppressions of the bailiffs: we hear of Gessler, of the meeting of Stoupacher of Schwyz, Fürst of Uri, and a man of Nidwald at the Rütli,—in fact, the usual version of the legend. To give an instance of tyranny in Uri, the author tells us the story of the refusal of "der Thäll" to do reverence to the hat placed on a pole, of his feat of skill, and of his shooting the bailiff, Gessler, from behind a bush in the "hollow way" near Küssnacht. Tell is represented as being one of those who swore at the Rütli to drive out the oppressors; but the narrative of his doings is merely one incident in the general movement which began quite independently of him. The chronology is very confused, but the events are placed after Rudolph's election to the empire in 1273. This is the only account in which Tell is called "der Thäll," which name he himself explains by saying, "If I were sharp (*witzig*) I should be called something else and not der Tall," *i.e.*, the simpleton or slow-witted man. The only other known instances of the Uri version of the legend relating to the origin of the Confederation are the Latin hexameters of Glareanus (1515), in which Tell is compared to Brutus as "assertor patriæ, vindex ultorque tyrannum," and the *Urnerspiel* (composed in 1511–12), a play acted in Uri, in which Russ's version is followed, though the bailiff, who is unnamed, but announces that he has been sent by Albert of Austria, is slain in the "hollow way." Tell is the chief of the Rütli leaguers, and it is his deed which is the immediate occasion of the rising against the oppressors, which is dated in 1296. Mutius (1540) is the latest writer who, in his description of the origin of the Confederation, does not mention Tell and his act. The two stories are now firmly bound together; the version contained in the *White Book* is the accepted one, though small additions in names and dates are often made.

The task of filling up gaps, smoothing away inconsistencies, rounding off the tale, was accomplished by Giles TSCHUDI (*q.v.*), whose recension was adopted, with a few alterations, by Von Müller in his *History of the Confederation* (1780). In the final recension of Tschudi's *Chronicle* (1734–36), which, however, differs in many particulars from the original draft still preserved at Zurich, we are told how Albert of Austria, with the view of depriving the Forest lands of their ancient freedom, sent bailiffs (among them Gessler) to Uri and Schwyz, who committed many tyrannical acts, so that finally on 8th November, 1307, at the Rütli, Werner von Stauffacher of Schwyz, Walter Fürst of Uri, Arnold von Melchthal in Unterwalden, each with ten companions, among whom was William Tell, resolved on a rising to expel the oppressors, which was fixed for New Year's day, 1308. A few days later (November 18) the Tell incident takes place (described according to the *White Book* version), and on the appointed date the general rising. Tschudi thus finally settled the date, which had before varied from 1260 to 1334. He utterly distorts the real historical relations of the Three Lands, though he brings in many real historical names, their owners being made to perform historically impossible acts, and introduces many small additions and corrections into the story as he had received it. In particular, while in his first draft he speaks of the bailiff as Gryssler—the usual name up to his time, except in the *White Book* and in Stumpff's *Chronicle* of 1548—in his final recension he calls him Gessler, knowing that this was a real name. Later writers added a few more particulars,—that Tell lived at Bürglen and fought at Morgarten (1598), that he was the son-in-law of Fürst and had two sons (early 18th century), etc. Johannes von Müller gave a vivid description of the oath at the Rütli by the three (Tell not being counted in), and threw Tschudi's version into a literary form, adding one or two names and adopting that of Hermann for Gessler, calling him of "Bruneck." Schiller's play gave the tale a world-wide renown.

The story was, on the ground of want of evidence, regarded as suspicious by Guilliman in a private letter of 1607, and doubts were expressed by the brothers Iselin (1727 and 1754) and by Voltaire (1754); but it was not till 1760 that the legend was definitely attacked, on the ground of its similarity to the story of Tokko (see below), in an anonymous pamphlet by Freudenberger, a Bernese pastor. This caused great stir; it was publicly burnt by order of the Government of Uri, and many more or less forged proofs and documents were produced in favor of Tell. The researches of J. E. Kopp[1] first cleared up the real early history of the league, and overthrew the legends of the *White Book* and Tschudi. Since then many writers have worked in the same direction. Vischer (1867) has carefully traced out the successive steps in the growth of the legend, and Rochholz (1877) has worked out the real history of Gessler as shown in authentic documents. The general result has been to show that a mythological marksman and an impossible bailiff bearing the name of a real family have been joined with confused and distorted reminiscences of the events of 1245–47, in which the names of many real persons have been inserted and many unauthenticated acts attributed to them.

The story of the skilful marksman who succeeds in striking some small object placed on the head of a man or child is very widely spread: we find it in Denmark (Tokko), Norway (two versions), Iceland, Holstein, on the Rhine, and in England (William of Cloudesley). How it came to be localized in Uri we do not know; possibly, through the story of the Scandinavian colonization of Schwyz, the tale was fitted to some real local hero.

The alleged proofs of the existence of a real William Tell in Uri in the 14th century break down hopelessly. (1) The entries in the parish registers are forged. (2) As to the Tell chapels—(*a*) that in the "hollow way" near Küssnacht was not known to Melchior Russ and is first mentioned by Tschudi (1570). (*b*) That on Tell's Platte is also first mentioned in Tschudi. The document which alleges that the chapel was built by order of a "landsgemeinde" held in 1388, at which 114 men were present who had been personally acquainted with Tell, was never heard of till 1759. The procession in boats to the place where the chapel stands may be very old, but is not connected with Tell till about 1582. (*c*) The chapel at Bürglen is known to have been founded in 1582. Other documents and statements in support of the Tell story have even less claim to credit. It has been pointed out above that with two exceptions the bailiff is always called Gryssler or Grissler, and it was Tschudi who popularized the name of Gessler, though Gessler occurs as late as 1765. Now Gessler is the name of a real family, the history of which from 1250 to 1513 has been worked out by Rochholz, who shows in detail that no member ever played the part attributed to the bailiff in the legend, or could have done so, and that the Gesslers could not have owned or dwelt at the castle of Küssnacht; nor could they have been called Von Bruneck.

In the *Urnerspiel* the name of the bailiff's servant who guarded the hat on the pole is given as Heintz Vögely, and we know that Friedrich Vögeli was the name of one of the chief military officers of Peter von Hagenbach, who from 1469 to 1474 administered for Charles the Bold, duke of Burgundy, the lands (Alsace, etc.) pledged to him by Sigismund of Hapsburg. Now Hagenbach is known to have committed many cruelties like those attributed to the bailiffs in the legend, and it has been plausibly conjectured that his case has really given rise to these stories, especially when we find that the Confederates had a hand in his capture and execution, that in a document of 1358 Hagenbachs and Gesslers appear side by side as witnesses, and that the Hagenbachs had frequent transactions with the Hapsburgs and their vassals.

Among the vast number of books and pamphlets on the Tell story, the two most to be recommended are W. Vischer, *Die Sage von der Befreiung der Waldstätte* Leipsic, 1867, and E. L. Rochholz, *Tell und Gessler*, with a volume of documents 1250–1513, Heilbronn, 1877. Convenient summaries of the controversy will be found in any modern book on Swiss history, and more particularly in G. von Wyss, *Ueber d. Gesch. d. drei Länder—Uri, Schwyz, u. Unterwalden—in den Jahren* 1212–1315, Zurich, 1858; Alf Huber, *Die Waldstätte bis zur festen Begründung ihrer Eidgenossenschaft, mit einem Anhange über die geschichtliche Stellung des Wilh. Tell*, Innsbruck, 1861; Albert Rilliet, *Les Origines de la Confédération Suisse, Histoire et Légende*, Geneva, 1869. (W. A. B. C.)

TELLER, WILHELM ABRAHAM (1734–1804), was the son of the Leipsic clergyman, Romanus Teller, who edited the earlier volumes of the *Englisches Bibelwerk* (in 19 vols., 1749–70), an adaptation for German readers of the exegetical works of Willet, Ainsworth, Patrick, Poole, Henry, and others. Teller was born at Leipsic on 9th January, 1734, and studied philosophy and theology in the university there. Amongst the men whose influence mainly determined his theological position and line of work was J. A. Ernesti. His writings present rationalism in its course of development from Biblical supernaturalism to the borders of deistical naturalism. His first learned production was a Latin translation of Kennicott's *Dissertation on the State of the Printed Hebrew Text of the Old Testament* (1756), which was followed the next year by an essay in which he expounded his own critical principles. In 1761 he was appointed pastor and professor of theology in the university of Helmstädt. Here he pursued his exegetical, theological, and historical researches, the results of which appeared in his *Lehrbuch des christlichen Glaubens* (1764). This work threw the entire theological world into commotion, as much by the novelty of its method as by the heterodoxy of its matter, and more by its omissions than by its positive teaching, though everywhere the author seeks to put theological doctrines in a decidedly modern form. In consequence of the storm of indignation the book provoked, Teller eagerly accepted an invitation from the Prussian cultus minister to the post of prebendary of Köln on the Spree, with a seat in the Berlin consistory (1767). Here he found himself in the company of the rationalistic theologians of Prussia—Sack, Spalding, and others—and became one of the leaders of the rationalistic party, and one of the chief contributors to Nicolai's *Allgemeine Deutsche Bibliothek*. Teller was not long in making use of his freer position in Berlin. In 1772 appeared the most popular of his books, *Wörterbuch zum Neuen Testament* (6th ed., 1805). The object of this work is to recast the language and ideas of the New Testament and give them the form of 18th-century illuminism. Thus Heb. xiii. 8 signifies the permanence of Christ's teaching, and, as the New Testament has no word for Christianity, "Christ" may mean sometimes His person and at others His doctrine or the Christian religion; Col. i. 15 signifies the priority of Christ to all other Christians. By this lexicon Teller had put himself amongst the most advanced rationalists, and his opponents charged him with the design of overthrowing positive Christianity altogether. The edict of Wöllner (1788), and Teller's manly action as consistorialrath in defiance of it, led the Prussian Government to pass upon him the sentence of suspension for three months, with forfeiture of his stipend. He was not, however, to be moved by such means, and (1792) issued his work *Die Religion der Vollkommeneren*, an exposition of his theological position, in which he advocated at length the idea, subsequently often urged, of "the perfectibility of Christianity,"—that is, of the ultimate transformation of Christianity into a scheme of simple morality, with a complete rejection of all specifically Christian ideas and methods. This book represents the culminating point of German illuminism, and is separated by a long process of development from the author's *Lehrbuch*. Teller died on 9th December, 1804. In addition to the above works he wrote *Anleitung zur Religion überhaupt und zum Allgemeinen des Christenthums insbesondere* (1792); and, besides his contributions to the *Allgemeine Deutsche Bibliothek*, he edited a popular and practically useful *Magazin für Prediger* (1792–1801).

1613 entered the order of the Brothers of Charity at Toledo. In 1645 he became prior of the monastery of the order at Soria, where he died in 1648.

His dramatic works are said to have numbered nearly 300, but of these only a small proportion are now extant. A selection of the best of them was edited by Hartzenbusch in 1839–42 (Madrid, 12 vols.). See Don Juan, vol. vii. p. 309, Drama, vol. vii. p. 364, and Spanish Literature, vol. xxii. p. 373.

TELLICHERRI, a seaport town of India, in Malabar district of Madras, situated in 11° 44′ 53″ N. lat. and 75° 31′ 38″ E. long. It is a healthy and picturesque town, built upon a group of wooded hills running down to the sea, and is protected by a natural breakwater of rock. The town with its suburbs occupies about 5 square miles, and was at one time defended by a strong mud wall. The citadel or castle still stands to the north of the town. The East India Company established a factory here in 1683 for the pepper and cardamom trade. For two years (1780–82) the town withstood a siege by Hyder's general Sardár Khán, and in the subsequent wars with Mysore Tellicherri was the base of operations for the ascent of the Ghâts from the west coast. In 1881 the population was 26,410.

TEMESVÁR, a royal free city and capital of the county of Temes, is the chief town of southeastern Hungary. It lies on the navigable Béga Canal and the river Béga, in 45° 47′ N. lat. and 21° 14′ E. long. The inner town is fortified and separated from the suburbs by a glacis, now partly converted into a park. Temesvár is the seat of the Roman Catholic bishop of Csanád and of a Greek bishop, as also of several Government departments of great importance, and of one of the fifteen army corps of the Austrian-Hungarian army. The majority of the inhabitants follow industrial and commercial pursuits, and carry on a brisk trade in grain, flour, spirits, fruits, flax, and hemp with the neighboring districts and with Roumania and Servia, by means of the Arad-Temesvár and the Austrian-Hungarian State Railways, as well as by the Béga Canal and by road. The town possesses many charitable and educational establishments, and is a favorite place of residence on account of its neatness and cleanliness. It has been lighted by electricity since 1883. Among the buildings specially worthy of notice are some fine old churches, a new theatre, and a synagogue in the Byzantine style. Temesvár played an important part in the Turkish wars and in that of 1848–49. The population was 37,500 in 1886.

TEMMINCK, Konrad Jacob (1778–1857), keeper of the Leyden museum of natural history, was especially distinguished as an ornithologist, and was the author of many magnificently illustrated systematic works. See Ornithology, vol. xviii. p. 15 *sq.*

TEMPE. See Thessaly.

TEMPERA, or Distemper,[1] is a method of painting in which solid pigments are employed, mixed with a water medium[2] in which some kind of gum or gelatinous substance is dissolved to prevent the colors from scaling off. Tempera is called in Italy "fresco a secco," as distinguished from "fresco buono," or true fresco, painted on freshly laid patches of stucco. The peculiarities of true fresco are described in vol. ix. p. 676 *sq.* The disadvantages of tempera painting are that it will not bear exposure to the weather; the pigments merely lie on the surface and do not sink into the stucco, as is the case with true fresco pigments; moreover, the medium used, being soluble in water, will not stand the rain. Its advantages are that the painter can work at leisure and can also transfer or sketch his whole design on the dry finished surface; while in fresco work each portion of the design is hidden piecemeal as each new patch of stucco is applied (see Raphael, vol. xx. p. 286). Another important point is that a far greater variety of pigments can be used in tempera painting, as they are not subjected to the caustic action of wet lime. Lastly, tempera painting can be applied to any substance, such as dry plaster, wood, stone, terracotta, vellum, and paper.[3] Various media have been used for tempera work, such as the glutinous sap of the fig and other trees, various gums which are soluble in water, and size made by boiling down fish-bones, parchment, and animals' hoofs. In more recent times a mixture of egg and vinegar has been found to make a good medium, especially when it is desirable to apply the colors in considerable body or *impasto*. Painting in tempera is probably the oldest method of all, and was used in ancient Egypt very largely, as can be seen by an examination of the many existing examples on papyrus or wood and stone thinly coated with a skin of fine plaster (*gesso*). Other ancient examples have been found in Babylon and Nineveh, and for internal work it appears to have been much employed by the Greeks. To some extent tempera was used by the Romans, though in most cases a combination of fresco and encaustic (hot wax) was employed for their mural decoration (see vol. xvii. p. 49).

In mediæval times, from the 6th century in the Byzantium of Justinian down to the 14th century, most painting, whether on walls or panels, was executed in tempera, though in many cases it appears to have been the custom to put in the colored ground in true fresco, and, when that was dry, paint on it the complete picture with a tempera medium. This was the method used in the Byzantine wall-paintings in the churches of Thessalonica, Mount Athos, and elsewhere. A similar practice existed in England and other northern countries,[4] as in the very complete series of paintings on the walls and vault of the chancel of Kempley church, Gloucestershire, dating from about 1100. Most commonly, however, in England as in France and Germany the whole painting was done in tempera, the finished surface of the plaster being first covered with a wash of old slaked lime or whitening. As a rule every inch of stone, whether carved, moulded, or plain, in the cathedrals and other churches of mediæval France, England, and other countries was covered with this thin coating of white, and then elaborately decorated with tempera painting. In those rare cases where want of money prevented the application of color the stone-work of the interior received the coat of white, so that at any future time the coloring might be added, and also because the feeling of the Middle Ages evidently was that bare stone inside a building had an unfinished and uncomfortable look,[5] and was quite as unsuitable in a richly decorated and furnished cathedral as it would now be considered in a lady's drawing-room. The additional splendor gained by the use of minute patterns stamped in gesso, thinly laid over the surface of the stone, is described in Mural Decoration, vol. xvii. p. 52; see also Fig. 17.

Tempera in Italy.—For panel and canvas paintings tempera continued in use till nearly the end of the 15th century, when the Flemish method of oil painting gradually took its place. In many cases with panel pictures of the latter part of the 15th century it is now difficult, if not impossible, to be sure whether they were painted in tempera or in oil, either because both methods were combined—the picture being begun in tempera and finished with oil glazings—or because an oil varnish has been laid over the tempera pictures, and so the pigments have absorbed oil out of the varnish and have thus practically become associated with an oil medium. In some cases slight peculiarities of brush-work bear witness to one medium or the other; but these appearances are often deceptive, and any real certainty on the point is unattainable. The round panel of the Madonna and St. Joseph by Michelangelo may be mentioned as an example of these doubtful cases.

---

[1] For some account of tempera painting in classical and mediæval times, see Mural Decoration, vol. xvii. pp. 40–54.

[2] Hence it used to be called "water-work"; see Shakespeare, *Hen. IV.*, part ii., act ii. sc. 1.

[3] Miniatures and illuminated letters in mediæval MSS. were painted with very finely ground colors mixed with a tempera medium.

[4] A fine example of 14th-century tempera painting in Sweden is illustrated in vol. xvii. plate I.

[5] Nothing could be more opposed to the spirit of the Middle Ages than the modern rage for cutting off plaster and scraping old stone-work, under a mistaken notion of æsthetic honesty.

In the main the earlier tempera easel pictures were painted on wood,—pear, poplar, or walnut being commonly used; but a few painters preferred in some cases to use canvas.[1] The National Gallery of London possesses a very beautiful example of this,—the Entombment, attributed to Van der Weyden (see SCHOOLS OF PAINTING, vol. xxi. p. 458, Fig. 29), which is most delicately and yet powerfully painted on linen without any priming. Usually both panels and canvas were prepared for tempera by being covered with a fine priming or coating of gesso (plaster). Some later painters used marble dust; others unfortunately used white lead, which has since blackened through the absorption of gases from the air.

In the case of wall paintings, both tempera and fresco[2] were used together,—the proportion of fresco work being gradually increased. In the 13th and most of the 14th century little more than the groundwork of the picture was painted in fresco, though this varied according to the custom of each painter. In the 15th century increased technical skill and rapidity of execution allowed much more complete work to be done in fresco, till at last nothing but a few finishing touches were done in tempera. For this, exceptional certainty of touch and speed of execution were required, and some weaker painters never attained to a very complete mastery over the fresco process. The brilliant series of wall paintings by Pinturicchio in the cathedral library at Siena contain a very large proportion of tempera work, in spite of which they are still in a wonderful state of preservation. Raphael's rapid advance in the mastery of fresco-work is clearly shown in his paintings in the Vatican stanze, each one of which is carried to a further stage in true fresco than the preceding. Thus the earliest painting of the series (the Disputa) is very largely executed in tempera, while some of the later ones are nearly completed in fresco, and show the most perfect skill in that difficult process. Michelangelo was specially remarkable for his great power in fresco, and carried his Sistine paintings to a very advanced stage before touching them with tempera. Sad to say, what tempera finishing touches he did apply have mostly been scraped off during the many cleanings and repairs that these works have undergone; and the same misfortune has happened to a large number of other important pictures. Tempera was specially used for paintings on canvas which were intended to be hung like tapestry, as, for example, the fine 15th-century series at Rheims and Mantegna's Triumph of Julius Cæsar at Hampton Court.[3] It was also much used for large cartoons, such as Raphael's tapestry designs, now in the South Kensington Museum. After the first half of the 16th century the increasing use of oil painting, assisted by the artistic decadence of the age, caused the gradual disuse of both fresco and tempera.

A third process, often used during the earlier Middle Ages, was a sort of compromise between tempera and fresco. A finished stucco surface was prepared as for ordinary tempera, but before each day's painting the plaster was soaked with water, so that the pigments, laid on to the wet plaster, to some extent sank below the surface, though without penetrating as deeply as they would on newly mixed stucco. (J. H. M.)

TEMPERANCE SOCIETIES.[4] The modern temperance movement may be said to date from the publication at Philadelphia, in 1785, of Dr. Benjamin Rush's essay on "The Effects of Ardent Spirits on the Human Body and Mind," which was republished in the *Gentleman's Magazine* of 1786, and had a wide circulation. The distinction which he draws between distilled and fermented liquors has, however, no foundation in fact, the difference being one of degree and not of kind. In 1808 Dr. Lyman Beecher and Dr. B. J. Clark, both readers of Rush, took action, and the result of the work of the latter was the formation of what is believed to be the first modern temperance society. It was formed in Greenfield, Saratoga county, New York, as an anti-spirits association, and still remains a teetotal society. This example was soon followed elsewhere, the early societies all restricting their scope to advocacy of moderation in the use of distilled liquors, and placing no inhibition upon fermented drinks. One society had a by-law requiring any member who became intoxicated to treat all the other members. The work made further progress when the American Temperance Society was founded in 1826. Three years later Prof. John Edgar of Belfast called attention to the need for similar work in Ireland; and John Dunlop nearly at the same time organized a temperance society in Glasgow. In 1830 the first English temperance society was founded at Bradford. The habitual use of fermented liquors in England was a prolific source of drunkenness, and the evil was greatly increased by the passing of the Beer Act in October, 1830. Hence some of the reformers began to abstain from all forms of alcohol. This new departure found its leader in Joseph Livesey of Preston, a man of singular zeal and benevolence, who with six others signed a pledge of total abstinence on 1st September, 1832. The reformers were soon divided over the fierce "battle of the pledges." Some were willing to pledge themselves to abstain, but not to refrain from providing alcoholic drink for their visitors. After the formation of the distinctive total abstinence organizations, the moderation societies died of inanition. It should be mentioned here that the Society of Bible Christians, founded at Salford in 1809, adopted the rule of abstinence from flesh meat and intoxicants, and that a number of the "radical reformers" were abstainers from a desire to diminish the public revenue, which they regarded as devoted to wrong purposes by the Government of the day. In Ireland Father Theobald Matthew became president of the Total Abstinence Society in Cork, in 1838, and the "pledge" was taken from his hands by crowds; before he died in 1856 between three and four million persons are said to have received it from him in the course of his journeys. J. S. Buckingham secured the appointment of a committee of the House of Commons, which sat in June, 1834, to inquire into drunkenness. The adjective "teetotal" was first used in September, 1833, by Richard Turner, a reformed drunkard, to express the thoroughgoing principle of total abstinence, but whether he coined the word, or whether it was merely a stuttering pronunciation of "total," or an old dialect word has been disputed; Prof. Skeat (*Etym. Dict. s.v.* "Teetotal") believes it is an emphasized form of "total," formed on the principle of reduplication. The early teetotallers were earnest missionaries. In consequence of their efforts societies and leagues multiplied, periodicals were established, and, notwithstanding many failures and apparent retrogressions, the temperance movement progressed. One of the chief forms of thrift amongst the artisan class was that of the friendly society, the meetings of which were usually held at the public-house, large sums being spent (sometimes by rule) on liquor. In 1835 the Independent Order of Rechabites was formed at Salford, and has since had a prosperous career as a working-class insurance company on temperance principles. The Sons of Temperance and the Total Abstinent Sons of the Phœnix are similar organizations. The sickness and death-rate among members of these bodies is much below that of the ordinary friendly societies. The beneficial effect of abstinence upon health and longevity is shown by the experience of the United Kingdom Temperance Provident Institution, the example of which has led several large insurance companies to add a special section for teetotallers. The statistics of these offices show that the mortality of the ordinary insured is considerably heavier than that of the abstainers. A vehement controversy arose at an early period as to the use of sacramental wine, and the nature of the wines mentioned in Scripture was discussed in innumerable pamphlets. The result has been that in a number of cases the wine now used for sacramental purposes is understood to be unfermented. The cosmopolitan character of the movement was shown by the meeting of the World's Temperance Convention at London in 1846. The Scotch United Presbyterian Abstinence Society, originated in 1845, was one of the first of the church societies; and there are now few, if any, religious denominations either in England or America in which such organizations are wholly wanting. The Church of England Temperance Society has two sections, one pledged to the temperate use of intoxicants and the other to total abstinence. This method of organizing has found imitators. The enactment of the Maine Liquor Law in America, in 1851 (see vol. xv. p. 302) led to the formation, in 1853, of the United Kingdom Alliance, which has for its object the suppression of the liquor traffic by legislation, and with a view to this suggests that a power of local veto should be placed in the hands of the rate-payers. This proposal took parliamentary form in the Permissive Bill of Sir Wilfrid Lawson, which was ultimately withdrawn and replaced by a "local option" resolution which has been thrice affirmed by the House of Commons. Temperance hotels, temperance cafés, British workmen public-houses, cocoa houses, coffee palaces, teetotal clubs, have arisen in many places as social aids of the temperance movement.

---

[1] In order to ensure an even surface some painters prepared their panels by covering them with linen or vellum, over which the gesso priming was laid.

[2] "Fresco" here means "fresco buono," or true fresco.

[3] See vol. xv. p. 509.

[4] The manner and degree in which the law has in recent years regulated the sale of intoxicants is described under LIQUOR LAW (vol. xiv. p. 694).

In 1868 the Good Templar order was introduced into England from the United States, where it had come into existence several years earlier. In England it made rapid progress, until it was seriously checked by a dispute arising out of the negro question; but the two sections have again reunited (1887). Good Templary is the freemasonry of temperance, with ritual, passwords, grips, etc., closely modelled on those of the old secret societies. It has had a remarkable extension in Great Britain, the United States, the British colonies, and in Scandinavia, its aggregate membership now reaching over 623,000. One of its results has been the foundation of a temperance orphanage at Sunbury-on-Thames. Side by side with the general movement there has been a special movement against the use of alcohol as medicine, and the tendency of medical teaching now favors at least restriction of its use as a therapeutic agent. The London Temperance Hospital for the non-alcoholic treatment of disease was opened in October, 1873. The importance of training the young was early recognized by the leaders of temperance reformation, and the labors of Dr. R. B. Grindrod of Manchester and Mrs. Carlile of Dublin led to the formation of bands of hope, which are now found in connection with many places of worship. The juvenile temples of the Good Templar order also work in the same direction. The Woman's Christian Temperance Union, founded in the United States in 1874, is one of the latest forms of temperance activity. A branch was organized in Great Britain in 1876; and in 1883 the World's Women's Temperance Union came into existence.

The temperance movement has now branched out into a multitude of organizations in the United Kingdom, of which the Railway Temperance Union, the post-office temperance societies, and associations connected with the army and navy are types. The organizations of a more general character are the United Kingdom Alliance, which is very active in the dissemination of teetotal doctrines generally, the National Temperance League, the Scottish Temperance League, the British Temperance League, the Scottish Permissive Bill Association, the Irish Temperance League, and the Irish Association for the Prevention of Intemperance. There are also large district and county societies. Next to these come the secret orders, of which the Rechabites, Sons of Temperance, Sons of the Phœnix, are large benefit societies. The Independent Order of Good Templars is non-beneficiary, and seeks in its "lodges" to provide social attractions, and at the same time to train the members in temperance work; it is probably the largest voluntary association in the world. There are societies in connection with the various religious bodies, of which the Church of England Temperance Society, the Catholic League of the Cross, the Baptist Total Abstinence Society, are prominent instances.

The oldest organization in America is the Sons of Temperance (1842), now numbering about 80,000 members. The Independent Order of Good Templars (1851) is the largest, its membership approaching 100,000. Both these, as also the Royal Templars of Temperance (1877) and the Templars of Honor and Temperance (1845), are mutual benefit societies. The Woman's Christian Temperance Union, the National Temperance Society and Publication House (New York), and the National Prohibition Party are active in educational work. The Woman's Christian Temperance Union is the outgrowth of "the Women's Crusade" (1872), a remarkable uprising among the women of Ohio and Pennsylvania against the liquor traffic. The organization was effected in 1874, and has since spread throughout the United States, its membership now (1887) numbering 207,000. Its influence has been widely felt in legislatures and in elections in which prohibitory laws have been voted upon. With the exception of the Church Temperance Society of the Protestant Episcopal Church, which has the "double basis," all the temperance societies of the United States are based on the doctrine of total abstinence; and, with the additional exception of the Father Mathew Total Abstinence Societies of the Roman Catholic Church, they all advocate the principle of prohibition. Amendments embodying this idea have been inserted in the State constitutions (by popular vote) of Maine, Kansas, and Rhode Island. In Vermont and Iowa the legislature has enacted statutory prohibition, which is still in force. In other States local prohibition prevails to a large extent, chiefly in Georgia, Mississippi, Massachusetts, Tennessee, Kentucky, and Arkansas.

Bibliography.—The literature of the subject is very extensive and may most conveniently be classed under the following heads. (1) History: P. T. Winskill, *History of the Temperance Reformation; One Hundred Years of Temperance* (New York, 1886); Dorchester, *Liquor Problem in all Ages* (New York); Willard, *Woman and Temperance* (Hartford); Shaw, *Great Temperance Reforms* (Toronto) [*Do not Carry Temperance into Politics* (Philadelphia, 1887]. (2) Theology: Dawson Burns and F. R. Lees, *Temperance Bible Commentary;* J. Smith, *The Church and the Temperance Reformation;* Samson, *Divine Law as to Wines* (Philadelphia). (3) General: A. Gustafson, *The Foundation of Death;* R. B. Grindrod, *Our Nation's Vice;* D. Burns, *Bases of the Temperance Reformation;* Grindrod, *Bacchus;* B. Parsons, *Anti-Bacchus;* Powell, *Bacchus Dethroned;* Baker, *The Curse of Britain;* J. Dunlop, *Philosophy of Drinking Usages* (1839); *The Political Prohibitionist* (New York, 1887); Pitman, *Alcohol and the State* (New York). (4) Political Economy: F. R. Lees, *Argument for the Prohibition of the Liquor Traffic;* W. Hoyle, *Our National Resources;* Hargreaves, *Our Wasted Resources* (New York). (5) Science: J. Livesey, *The Malt Liquor Lecture;* P. Burne, *Teetotaller's Companion;* W. B. Carpenter, *Physiology of Temperance and Total Abstinence;* A. A. Reade, *Study and Stimulants;* Miller, *Alcohol, its Place and Power;* Id., *Nephalism;* B. W. Richardson, *Cantor Lectures on Alcohol;* Hargreaves, *Alcohol and Science* (New York). (6) Fiction: novels and tales embodying teetotal principles have been written by Mrs. Henry Wood, Mrs. H. B. Stowe, Mrs. C. L. Balfour, Mr. John Habberton, Mr. Edward Jenkins, Mrs. S. C. Hall, Mrs. Ellis, and many others. (7) Periodicals: the temperance periodicals issued in Great Britain now number about fifty.

TEMPLARS, Knights. Perhaps the most renowned of the three great military orders founded in the 12th century for the defence of the Latin Kingdom of Jerusalem is that of the Knights Templars (*pauperes commilitones Christi templique Salomonici*), though abolished long before its rivals. It differed from the Hospitallers and the Teutonic Knights in having been a military order from its very origin, inasmuch as its earliest members banded themselves together for the express purpose of giving armed protection to the numerous pilgrims who, after the first crusade, flocked to Jerusalem and the other sacred sites in the Holy Land. Walter Map has preserved the legendary story of their first achievements, from which it would appear that their earliest efforts were confined to the immediate neighborhood of Jerusalem; and the memory of their original aim may perhaps be traced from fifty to seventy years later, when they conducted Henry of Saxony from their own quarters on Mount Moriah to the banks of Jordan, or when on the fall of the Holy City (1187) they protected the vanguard of the Christians on its way from Jerusalem to Tripoli. The three orders were distinguished from each other by their garb. The Hospitallers wore black mantles with white crosses, the Templars white mantles with a red cross, the Teutonic Knights white mantles with a black cross.[1]

The Templars almost from their foundation had their quarters in the palace of the Latin kings, which had been the mosque of Mount Moriah. This palace was also known as Solomon's temple, and it was from this *templum Salomonis* that the Templars took their name.

Origin.

About the year 1118 a Burgundian knight, Hugh de Paganis, bound himself and eight comrades by a vow to the patriarch of Jerusalem to guard the public roads, to live as regular canons, and to fight for the King of Heaven in chastity, obedience, and self-denial. Baldwin II. granted them quarters on Mount Moriah and recommended their cause to St. Bernard. Under his patronage the papal legate, Matthew, bishop of St. Albano, presided at the council of Troyes in January, 1128, for the purpose of drawing up or confirming the statutes of the new order. The seventy-two statutes then drawn up met with the approval of Pope Honorius II. and the patriarch of Jerusalem, and became the groundwork of the later and more elaborate "*Règle du Temple.*" Long before St. Bernard's death (1153) the new order was established in almost every kingdom of Latin Christendom. Henry I. granted them lands in Normandy. They seem to have been settled in Castile by 1129, in Rochelle by 1131, in Languedoc by 1136, at Rome by 1138, in Brittany by 1141, and in Germany at perhaps a still earlier date. Alphonso I. of Aragon and Navarre, if we may trust the Spanish historians, bequeathed them the third of his kingdom (Mariana, x. c. 9). Raymond Berengar, count of Barcelona, and Alphonso's successor in Aragon, whose father had been admitted to the order, granted them the strong castle of Monçon (1143), and established a new chivalry in imitation of theirs. Louis VII. in the latter years of his reign gave them a piece of marsh land outside Paris, which in later times became known as the temple, and was the headquarters of the order in Europe. Stephen of England granted them the manors of Cressing and Witham in Essex, and his wife Matilda that of Cowley, near Oxford. Eugenius III., Louis VII., and 130 brethren were present at the Paris chapter (1147) when Bernard de Balliol granted the order 15 librates of land near Hitchin; and the list of English benefactors under Stephen and Henry II. includes the noble names of Ferrers, Harcourt, Hastings, Lacy, Clare, Vere, and Mowbray.

Spread of the order.

After the council of Troyes Hugh de Paganis came to England and induced a number of English knights to follow him to the Holy Land. Amongst these was Fulk, count of Anjou, who would seem to have been a Templar before assuming the crown of Jerusalem in 1131. Hugh de Paganis died about the year 1136 and was succeeded by Robert de Craon, who is said to have been Anselm's nephew. Everard de Barris, the third master, was conspicuous in the second crusade. In the disastrous march from Laodicea to Attalia his troops alone kept up even the show of discipline; and their success prompted Louis VII. to regulate his whole army after the model of the Templar knights. In the French king's distress for money the Templars lent him large sums, ranging from 2000 silver marks to 30,000 solidi. When Conrad III. of Germany reached Jerusalem he was entertained at their palace (Easter 1148); and in the summer of the same year they took part in the unsuccessful siege of Damascus. The failure of this expedition was ascribed by a contemporary writer to their treachery,—a charge to which Conrad would not assent. This is the first note of the accusations which from this time were of constant recurrence.[2]

Early grand-masters.

Henceforward for 140 years the history of the Templars is the history of the **CRUSADES** (*q.v.*). In 1149 the Templars were appointed to guard the fortress of Gaza, the last Christian stronghold on the way towards Egypt. Four years later the new master, Bernard de Tremelai, and forty of his followers, bursting into Ascalon, were surrounded by the Saracens and cut off to a single man. William of Tyre has preserved the scandal of the day when he hints that they met a merited fate in their eagerness to possess themselves of the city treasure. Next year the rumor went abroad that they had sold a noble half-converted Egyptian prince, who had fallen into their hands, to chains and certain death for 60,000 aurei [$258,187.50]. In 1166, Amalric, the Latin king of Jerusalem, hanged twelve Templars on a charge of betraying a fortress beyond the Jordan to an emir of Núr al-Dín of Damascus. The military power of Núr al-Dín (1145–1173) was a standing menace to the Christian settlements in the East. Edessa had fallen to the prowess of his father (1144–45); Damascus was conquered by the son (1153), who four years earlier had carried his depredations almost to the walls of Antioch, and in 1157 laid siege to the Christian town of Paneas near the sources of the Jordan. In the disastrous fight that followed for the safety of the fortress of the Hospitallers, Bertrand de Blanquefort, the master of the Templars, and Odo de St. Amand, one of his successors, were taken prisoners. Bertrand was released later when Manuel was preparing to march against Núr al-Dín. The Templars do not seem to have opposed Amalric's early expeditions against Egypt. It was Geoffrey Fulcher, the Templar correspondent of Louis VII., who brought back (1167) to Jerusalem the glowing accounts of the splendor of the caliph's court at Cairo with which Gibbon has enlivened his great work. Nor was the order less active at the northern limits of the Latin kingdom. Two English Templars, Gilbert de Lacy and Robert Mansel, "qui Galensibus præerat," starting from Antioch, surprised Núr al-Dín in the neighborhood of Tripoli and put him bare-footed to flight. But jealousy or honor led the Templars to oppose Amalric's Egyptian expedition of 1168; and the wisdom of their advice became apparent when the renewed discord on the Nile led to the conquest of Egypt by Asad al-Dín Shírkúh, and thus indirectly to the accession of Saladin, in 1169. In 1170, they beat Saladin back from their frontier fortress of Gaza; and seven years later they shared in Baldwin IV.'s great victory at Ascalon.

Relations with Núr al-Dín.

Relations with Saladin.

Meanwhile Saladin had possessed himself of Emesa and Damascus (1174–75), and, as he was already lord of Egypt, his power hemmed in the Latin kingdom on every side. In July, 1173, Amalric was succeeded by his son Baldwin IV., a boy of twelve. Raymond III., count of Tripoli, a man suspected of being in league with the Saracens, was appointed regent, although in 1176 the masters of the Templars and the Hospitallers united in offering this office to the newly arrived Philip of Flanders. The construction of the Templar fortress at Jacob's ford on the upper Jordan led to a fresh Saracen invasion and the disastrous battle of Paneas (1179), from which the young king and the Holy Cross escaped with difficulty, while Odo de St. Amand, the grand-master, was carried away captive and never returned.

[2] *Hist. Pontific.*, ap. Pertz, xx. 535–536.

During Odo's mastership the Old Man of the Mountains sent to Amalric offering to accept the Christian faith if released from the tribute he had paid to the Templars since (according to the reckoning of M. Defrémery) somewhere about 1149. The Templars murdered the envoys on their return (*c.* 1172). Amalric demanded that the offenders should be given up for justice. Odo refused to yield the chief culprit, though he was well known, and invoked the protection of the pope. Amalric had to vindicate his right by force of arms at Sidon, and died while preparing to take stronger measures. The connection between the Templars and the Old Man was still vital eighty years later when the two grand-masters rebuked the insolence of the Assassin envoys in the presence of Louis IX. Odo de St. Amand was succeeded by Arnold de Torroge, who died at Verona on his way to implore European succor for the Holy Land. The power of Saladin was now (1184) increasing daily; Baldwin IV. was a leper, and his realm was a prey to rival factions. There were two claimants for the guardianship of the state,—Raymond III. of Tripoli and Guy de Lusignan, who in 1180 had married Sibylla, sister of the young king. Baldwin inclined to the former, against the patriarch and Arnold de Torroge.

Fall of Latin kingdom.

Fall of Jerusalem.

Siege of Acre.

There is something Homeric in the story of the fall of the Latin kingdom as related by the historians of the next century. A French knight, Gerard de Riderfort or Bideford, coming to the East in quest of fortune, attached himself to the service of Raymond of Tripoli, looking for the hand of some wealthy widow in reward. But on his claiming the hand of the lady of Botron he was met with a refusal. Angered at this, Gerard enrolled himself among the Templars, biding his time for revenge, and was elected grand-master on the death of Arnold. Baldwin IV. died (1185), leaving the throne to his young nephew Baldwin V., the son of Sibylla, under the guardianship of Raymond, whose office was not of long duration, as the little king died in September, 1186. This was Gerard's opportunity. The Templars carried the body of their dead sovereign to Jerusalem for burial; and then, unknown to the barons of the realm, Gerard and the patriarch crowned Sibylla and her husband Guy. The coronation of Guy was the triumph of Reginald of Châtillon, once prince of Antioch, and Saladin's deadliest foe. It was at the same time the overthrow of Raymond's ambition; and both Latin and Arabic writers are agreed that the Christian count and the Mohammedan sultan now entered into an alliance. To break this friendship and so save the kingdom, the two grand-masters were sent north to make terms with Raymond. But the rash valor of the Templars provoked a hopeless contest with 7000 Saracens. The grand-master of the Hospitallers was slain; but Gerard made his escape with three knights to Nazareth (1st May, 1187). In this emergency Raymond became reconciled with Guy; and Gerard placed the temple treasures of Henry II. at his king's disposal. Once more it was the Templars' rashness that led to the disastrous battle of Hittin (4th July). Gerard and the king fell into the hands of Saladin, but were released about a year later: Raymond of Tripoli made his escape through treachery or fortune; and 230 Templars fell in or after the battle, for the fight was scarcely over before Saladin ordered all the Templars and Hospitallers to be murdered in cold blood. One after another the Christian fortresses of Palestine fell into the hands of Saladin. Jerusalem surrendered on 2d–3d October, 1187, and the treasures of the temple coffers were used to purchase the redemption of the poorer Christians, part of whom the Templar warriors guarded on their sad march from the Holy City to Tripoli. Part of their wealth was expended by Conrad of Montferrat in the defence of Tyre; but, when this prince refused to admit Guy to his city, both the Templars and the Hospitallers from the neighboring parts flocked to the banner of their released king and accompanied him to the siege of Acre (22d August, 1189). In his company they bore their part in the two years' siege and the terrible famine of 1190–91; and their grand-master died in the great battle of 4th October, 1189, refusing to survive the slaughter of his brethren.

John de Brienne.

On the fall of Acre, Philip Augustus established himself in the palace of the Templars, who are, however, stated to have sympathized with Richard. This king sold them the island of Cyprus for 100,000 besants [$218,700]; but unable to pay the purchase money, they transferred the debt and the principality to Guy of Lusignan. The English king consulted them before deciding on any great military movement; and in June, 1192, they advocated the bold plan of an advance on Egypt rather than on Jerusalem. In the disputes for the Latin kingdom of the East the Templars seem to have supported Guy, and, like Richard, were credited with having had a hand in the murder of Conrad of Montferrat (April, 1192). It was in the disguise of a Templar and in a Templar galley that Richard left the Holy Land. When Acre was recovered, the Templars, like the Hospitallers, received their own quarters in the town, which from this time became the centre of the order. On the death of Henry of Champagne (1197) they vetoed the election of Raoul de Tabarie; after the death of his successor Amalric they refused to renew the truce with Saladin's brother, Saif al-Dín, and led an expedition against the Saracens before the arrival of the new king, John de Brienne, at whose coronation in 1210 William de Chartres, the grand-master, was present. Seven years later, with the aid of Walter de Avennis and of the Teutonic Knights, they commenced the building of their fortress of Castle Pilgrim, near Acre, on a rocky promontory washed by the Mediterranean on every side except the east. This wonderful structure, whose ruins are still to be seen, was fortified with a strong wall, founded on the substructure of a yet more extensive one running from sea to sea, and was flanked by lofty towers of huge square stones. Within was a spring of pure water, besides fishponds, salt-mines, woods, pastures, orchards, and all things fitted to furnish an abode in which the Templars might await the day of their restoration to Jerusalem.

Fifth crusade.

It was from this castle that in May, 1218, the fifth crusade started for the expedition against Egypt. The Templars were the heroes of the siege of Damietta, at which William de Chartres was slain. "First to attack and last to retreat," they saved the Christian army from annihilation on 29th August, 1219; and when the city surrendered (5th November) the only one of its twenty-eight towers that had begun to give way had been shaken by their engines. On the other hand, it was largely owing to their objections that John de Brienne refused the sultan's offer to restore Jerusalem and Palestine.

From the very first the Templars seem to have been opposed to Frederick II., and when he landed at Acre (7th September, 1228) they refused to march under the banners of an excommunicated man, and would only accompany his host from Acre to Joppa in a separate body. They were accused of notifying Frederick's intended pilgrimage to the Jordan to the sultan, and they were certainly opposed to Frederick's ten years' peace with Al-Kámil, the sultan of Egypt, and refused to be present at his coronation in Jerusalem. Frederick was not slow to avenge himself: he left Jerusalem abruptly, publicly insulted the grand-master, demanded the surrender of their fortresses, and even laid siege to Castle Pilgrim. He left Acre on 3d May, 1229, and on landing in Apulia gave orders to seize the estates of the order and chase all its members from the land.

Seventh crusade.

Long before the expiration of Frederick's peace Europe was preparing for a fresh crusade against the now divided realm of the Ayyubids. Theobald of Navarre and his crusaders reached Palestine about August, 1239. The Templars shared in the great defeat near Jaffa, an engagement which their temerity had done much to provoke (13th November, 1239). If the king ever accepted the overtures of Şáliḥ of Damascus, he was supporting the policy of Hermann of Perigord, the grand-master, who towards the summer of 1244 wrote a triumphant letter to England, telling how he had engaged this sultan and Násir of Kerak to make an alliance against the sultan of Egypt and restore the whole of Palestine from the Jordan to the sea. Theobald, however, before leaving the Holy Land (27th September, 1240), signed a ten years' truce with Şáliḥ of Egypt. The Hospitallers seem to have been won over to his view, and when Richard of Cornwall arrived (11th October) he had to decide between the two rival orders and their opposing policies. After some hesitation he concluded a treaty with the sultan of Egypt, much to the annoyance of the Templars, who openly mocked his efforts. On his departure the three orders came to open discord; the Templars laid siege to the Hospitallers in Acre and drove out the Teutonic Knights "in contumeliam imperatoris." They were successful on all sides. The negotiations with Damascus and Kerak were reopened, and in 1244 Hermann of Perigord wrote to the princes of Europe that after a "silence of fifty-six years the divine mysteries would once more be celebrated in the Holy City."

Khárizmian invasion.

It was in this moment of danger that the sultan of Babylon called in the barbarous Khárizmians, whom the Mongol invasions had driven from their native lands. These savages, entering from the north, flowed like a tide past the newly built and impregnable Templar fortress of Safed, swept down on Jerusalem, and annihilated the Christian army near Gaza on St. Luke's day (18th October), 1244. From this blow the Latin kingdom of the East never recovered; 600 knights took part in the battle; the whole army of the Templars, 300 in number, was present, but only 18 survived, and of 200 Hospitallers only 16. The masters of both orders were slain or taken prisoners. Despite the admirable valor of the Templars, their policy had proved the ruin of the land. Jerusalem was lost to Christendom forever; and, though the Khárizmians melted away in the course of the next three years, they left the country so weak that all the acquisitions of Theobald and Richard fell an easy prey to the sultan of Babylon.

Louis IX.'s crusade.

Recognizing the fact that the true way to Jerusalem lay through Egypt, Louis IX. led his host to the banks of the Nile, being accompanied by the Templars. Their master, William de Sonnac, attempted in vain to restrain the rash advance of the count of Artois at the battle of Manşúra (8th February, 1250), which only three Templars survived. St. Louis, when captured a few weeks later, owed his speedy release to the generosity with which the order advanced his ransom-money. Shortly after his departure from Acre (April, 1254) they consented to an eleven years' truce with the sultans of Egypt and Damascus.

Successes of Beybars.

A new enemy was now threatening Mohammedan and Christian alike. For a time the Mongol advance may have been welcomed by the Christian cities, as one after another the Mohammedan principalities of the north fell before the new invaders. But this new danger stimulated the energies of Egypt, which under the Mameluke Beybars (see vol. vii. pp. 655–6) encroached year after year on the scanty remains of the Latin kingdom. The great Frankish lords, fearing that all was lost, made haste to sell their lands to the Templars and Hospitallers before quitting Palestine forever. In 1260 the former purchased Sidon and Beaufort; next year the Hospitallers purchased Arsuf. In 1267, by a skilful adaptation of the banners of both orders, Beybars nearly surprised Antioch. The Templar fortress of Safed surrendered with its garrison of 600 knights, all of whom preferred death to apostasy (June, 1266). Beaufort fell in April, 1268, Antioch six weeks later; and, though the two orders still made occasional brilliant dashes from their Acre stronghold, such as that to Ascalon in 1264 and that with Prince Edward of England to destroy Ķáķún in 1271, they became so enfeebled as to welcome the treaty which secured them the plain of Acre and a free road to Nazareth as the result of the English crusade of 1272.

But, though weak against external foes, the Templars were strong enough for internal warfare. In 1277 they espoused the quarrel of the bishop of Tripoli, formerly a member of the order, against his nephew Bohemond, prince of Antioch and Tripoli, and commenced a war which lasted three years. In 1276 their conduct drove Hugh III., king of Cyprus and Jerusalem, from Acre to Tyre. In the ensuing year, when Mary of Antioch had sold her claim to the crown to Charles of Anjou, they welcomed this prince's lieutenant to Acre and succeeded for the moment in forcing the knights of that city to do homage to the new king. Thirteen years later (26th April, 1290) Tripoli fell, and next year Acre, after a siege of six weeks, at the close of which (16th May) William de Beaujeu, the grand-master, was slain. The few surviving Templars elected a new master, and, forcing their way to the seashore, sailed for Cyprus, which now became the headquarters of the order. A futile attempt against Alexandria in 1300 and an unsuccessful effort to form a new settlement at Tortosa about the same time (1300–2) are the closing acts of their long career in the western parts of Asia.

Abandonment of Palestine.

Power and influence of the order.

For more than a hundred years the Templars had been one of the wealthiest and most influential factors in European politics. If we confine our attention to the East, we realize but a small part of their enormous power. Two Templars were appointed guardians of the disputed castles on the betrothal of Prince Henry of England and the French princess in 1161. Other Templars were almoners of Henry III. of England and of Philip IV. of France. One grand-master was godfather to a daughter of Louis IX.; another, despite the prohibition of the order, is said to have been godfather to a child of Philip IV. They are reported to have reckoned a pope (Innocent III.) among their members and to have refused admission to a king and his nephew (Philip IV.). They were summoned to the great councils of the church, such as the Lateran of 1215 and the Lyons council of 1274. Frederick II.'s persecution of their order was one of the main causes of his excommunication in 1239; and his last will enjoined the restoration of their estates. Their property was scattered over every country of Christendom, from Denmark to Spain, from Ireland to Cyprus. Before the middle of the 13th century Matthew Paris reckons their manors at 9000, Alberic of Trois-Fontaines at 7050, whereas the rival order of St. John had barely half the latter number. Some fifty years earlier their income from Armenia alone was 20,000 besants [$43,740]. Both in Paris and in London their houses were used as strongholds for the royal treasure. In the London temple Hubert de Burgh and the Poitevin favorites of Henry III. stored their wealth; and the same building was used as a bank into which the debtors of the foreign usurers paid their dues. From the English Templars Henry III. borrowed the purchase money of Oléron in 1235; from the French Templars Philip IV. exacted the dowry of his daughter Isabella on her marriage with Edward II. To Louis IX. they lent a great part of his ransom, and to Edward I. of England no less than 25,000 *livres Tournois* [$5062.50], of which they remitted four-fifths. James de Molai, the last grand-master, came to France in 1306 with 150,000 gold florins [$381,271.50] and ten horse-loads of silver. In the Spanish peninsula they occupied a peculiar position, and more than one king of Aragon is said to have been brought up under their discipline.

Such were the power and wealth of the Templars at the time when Philip IV. of France accused them of heresy and worse offences, had them arrested (13th October, 1307), and forced them to confess by tortures of the most excruciating kinds. Five years later (26th May, 1312) the order was suppressed by decree of the council of Vienne and its goods transferred to the hospital of St. John.

Constitution.

The order consisted of (1) knights, (2) chaplains, and (3) men-at-arms (*armigeri*, *clientes*, and *servientes*). The knights were either bound for life or for a fixed period, and were the only members entitled to wear the white mantle. Married brethren were admitted; but no woman might enter the order. Each knight might keep three horses and one man-at-arms, who, like his master, might be bound for life or only for a time. Like Augustinian canons, they were to attend daily services; but the soldier outwearied with his nightly duties might on certain conditions absent himself from matins with the master's consent. Two regular meals were allowed for each day; but to these might be added, at the master's discretion, a light collation towards sunset. Meat might be eaten thrice a week; and on other days there was to be a choice of vegetable fare so as to suit the tenderest stomach. Brethren were to eat by couples, each keeping an eye on his fellow to see that he did not practice an undue austerity. Wine was served at every meal, and at those times silence was strictly enjoined that the words of Holy Writ might be heard with the closest attention. Special care was to be taken of aged and ailing members. Every brother owed the most absolute obedience to the master of the order, and was to go wherever his superior bade him without delay, "as if commanded by God." All undue display in arms or harness was forbidden. Parti-colored garments were forbidden; black or dusky-brown (*burellus*) was to be worn by all except the knights. All garments were to be made of wool; but from Easter to All Souls a linen shirt might be substituted for one of wool. The hair was to be worn short, and a rough beard became one of the distinguishing marks of the order. Hunting and hawking were unlawful; and the very allusion to the follies or secular achievements of earlier life was forbidden. A lion, however, being the type of the evil one, was legitimate prey. Strict watch was kept on the incomings and outgoings of every brother, except when he went out by night to visit the Sepulchre of our Lord. No letter, even from the nearest relative, might be opened except in the master's presence; nor was any member to feel annoyance if he saw his relative's gift transferred at the master's bidding to some other brother. The brethren were to sleep in separate beds in shirts and breeches, with a light always burning in the dormitory. Those who lacked a mattress might place a piece of carpet on the floor; but all luxury was discouraged. The order recognized two governing bodies,—the first, a meeting for ordinary business, to which only the wiser members were summoned; the second, one for extraordinary affairs, such as the granting of lands or the reception of new members, on which occasions the master might summon the whole community. Even at these last assemblies the master seems to have decided on the final action (c. 59). A term of probation was assigned to each candidate before admission; and a special clause discouraged the reception of boys before they were of an age to bear arms. Lastly, the brethren of the Temple were exhorted to shun the kiss of every woman, whether maid or widow, mother, aunt, or sister.

Administration.

The general spirit of the Templar statutes remained unaltered to the end, though the increasing wealth of the order gave rise to a number of additional rules. The grand-master was always head of the society; his instructions were binding on every member, and the very laws were at his discretion. But he could not declare war, alienate the society's estates, or even admit a member without the consent of his chapter. He was elected by thirteen brothers, chosen by a peculiar method of co-optation, and all, if possible, belonging to different nations. Next to him in dignity came the seneschal, on whom the duties of the absent master devolved. The marshal had charge of the steeds and accoutrements; he also commanded the knights and men-at-arms, the latter of whom seem in time of war to have been at the disposal of the turcopolier. The commander of the kingdom guarded the treasure-house, to which even the grand-master might not have a key; the commander of the city of Jerusalem had charge of the True Cross in time of war. There were twelve or perhaps more commanders or preceptors of the different provinces and kingdoms of Europe and Asia,—Jerusalem (kingdom and city), Acre, Tripoli, Antioch, France, England, Poitou, Aragon, Portugal, Apulia, and Hungary. No European preceptor could cross the sea without the grand-master's leave; but all ought to be present at the election to this office. The privileges and duties of every member were strictly prescribed, from the number of horses he might ride and the amount of food he might eat to the color of his clothes. The order seems to have owned a fleet, part of which, if not all, was under the authority of the commander of the kingdom. Besides the knights and men-at-arms, the society reckoned chaplains in its ranks; and it was the habit of confession to these priests that seems to have stirred the wrath of the Dominicans and the Franciscans, who played a very conspicuous part in the overthrow of the order, especially in England. For grievous offences, such as desertion to the Saracens, heresy, or losing the gonfalon, a Templar might be expelled (*perdre la maison*); for minor offences, such as disobedience or lowering the banner in battle, he suffered a temporary degradation (*perdre son abit*). By a mutual agreement the Templars and Hospitallers, despite their long and deadly feud, were bound not to receive ejected members of the rival order; and the Templar cut off in battle and defeat from all hope of rejoining his own ranks might rally to the cross of St. John. As Acre was the headquarters of the order in the East, so Paris was its centre in the West (Matt. Paris, v. 478). Every member before admission must declare himself free of debt, sound of body, and affiliated to no other religious society; he must also take a vow of obedience and chastity, at the same time renouncing his private property and dedicating his future life to the Holy Land. The order prided itself specially on the splendor of its religious services, the abundance of its alms, and its reckless valor for the Christian faith. At the time of its suppression it was calculated to number 15,000 members. Three MSS. of its ancient statutes, written in Old French, are still extant at Dijon, at Paris, and at Rome. Of these the first was transcribed about 1200, the last two from 1250 to 1300. They have been published by M. Maillard de Chambure (Paris, 1840).

Suppression of the order.

A scheme for the union of the three great military orders into one had received the sanction of Gregory X. and Louis IX., of Nicholas IV. and Boniface VIII. The recovery of the Holy Land was the dream of the last pope's highest ambition; and when he died a prisoner in the hands of Philip IV. of France this king continued to advocate the plan for his own purposes. His gold or influence secured the election of Clement V. as pope (5th June, 1305). According to a slightly later tradition, before consenting to the new pope's appointment he exacted from him an oath to assist in carrying out six propositions, one of which he would not disclose as yet. This sixth condition, if it ever existed, must have been the suppression of the Templars; and, whether false or true, Villani's story emphasizes a popular and almost contemporary opinion. It is known that Philip was urging Clement in this direction before the latter's coronation at Lyons on 14th November, 1305, and all through the two succeeding years. On 6th June, 1306, the pope summoned the grand-master from Cyprus to France. James de Molai obeyed the call, and, hearing of the charges against his order, demanded a prompt investigation. In this demand he was supported by the leading Templars of the realm. Clement, who disbelieved the accusations, fenced with the question. But, though only a very short time previously Philip had spoken of his special love for the order, and though it had sheltered him from the fury of the Paris mob in 1306, he was now determined on its destruction. Its wealth would fill the royal coffers, and the rumors of the day afforded a ready engine for its overthrow.

Accusations.

For perhaps half a century there had been strange stories circulating as to the secret rites practiced by the order at its midnight meetings. It was said that on his initiation each member had to disavow his belief in God and Christ, to spit upon the crucifix, to submit to indecent ceremonies, and to swear never to reveal the secrets of the society or disobey the mandates of a grand-master, who claimed full power of absolution. When the mass was celebrated the consecrating words "Hoc est corpus" were omitted; on Good Friday the holy cross was trampled under foot; and the Christian duty of almsgiving had ceased to be observed. Even the vaunted chastity of the order towards women had, it was said, been turned into a sanction for more horrible offences. These evil practices were part of the secret statute law of an order which in its nightly assemblies worshipped hideous four-footed figures,—a cat or a calf. In England the very children at their play bade one another beware of a Templar's kisses. Stranger stories yet were rife in this country and gravely reported before bishops and priests,—of children slain by their fathers because they chanced to witness the nightly orgies of the society; of one prior's being spirited away at every meeting of the general chapter; of the great preceptor's declaring that a single hair of a Saracen's beard was worth more than the whole body of a Christian man. In France they were said to roast their illegitimate children and smear their idols with the burning fat.

Suppression of order in France.

For nearly two years Philip waited for Clement to fulfil his bargain. A certain Templar from the prisons of Toulouse now offered to put the king in possession of a secret that would be worth a realm. Acting on the evidence of this informer, Philip issued orders (14th September, 1307) for the arrest of all the Templars in France on the night of Friday, 13th October. He seems to have written to the neighboring princes urging them to act in the same way. James de Molai was seized with sixty of his brethren in Paris. On Saturday they were brought before the university of Paris to hear the enumeration of their crimes; and on Sunday the Paris mob was gathered in the royal gardens, where preachers were inveighing against the iniquities of the order. The inquisitors began their work at once; and inhuman tortures forced the most horrible avowals from the lips of many. In Paris alone thirty-six Templars died under torture.[1] Of 140 Templars examined at Paris between 19th October and 24th November, 1307, the experience of some of whom extended over nearly half a century, there is hardly one who did not admit the dishonoring of the crucifix at his reception. Very many confessed to other charges, even of the worst description. Clement V., although he suspended the inquisitor's powers on 27th October (Loiseleur, 159), before the end of the next month wrote to Edward II. to arrest all the English Templars, who were accordingly seized on 10th January, 1308. About the same time they were arrested in Sicily (24th January) and in Cyprus (27th May). As Clement did not move fast enough, Philip went to Poitiers with 700 armed men, and the pope was at his mercy. It was agreed that the prisoners, their lands, and their money should be nominally placed in the hands of Clement's commissioners. The power of the inquisitors was restored (5th July); and the property forfeited was to be devoted to the recovery of the Holy Land. Clement now gave orders for fresh diocesan inquiries, into the guilt of the Templars. He had already heard the confessions of seventy-two at Poitiers (29th June to 1st July). The grand-master and the three preceptors were re-examined at Chinon, and renewed their old confessions (20th August). Lastly, the bull *Regnans in Cœlo* summoned a great council at Vienne for 1st October, 1310, when the question of the guilt of the order might be considered. The diocesan councils were only empowered to inquire into the conduct of individuals.

The trial.

The trial began on 11th April, 1310. On 23d April Reginald de Pruino protested against the unfairness of the proceedings. On Tuesday, 12th May, fifty-four Templars were burnt by order of the archbishop of Sens, and a few days later four more. Next day the terror spread (19th May). Forty-six Templars withdrew their defence and the commissioners decided (30th May) to adjourn till November. The second examination lasted from 18th December, 1310, to 5th June, 1311. Meanwhile (*c.* April, 1311) Clement and Philip had come to terms. The pope condemned the Templars. The council of Vienne met in October, 1311. A discussion arose as to whether the Templars should be heard in their own defence. Clement, it is said, broke up the session to avoid compliance; and when seven Templars offered themselves as deputies for the defence he had them cast into prison. Towards the beginning of March Philip came to Vienne, and he was seated at the pope's right hand when that pontiff delivered his sermon against the Templars (3d April, 1312), whose order had just been abolished, not at the general council, but in private consistory (22d March). On 2d May, 1312, he published the bull *Ad Providam*, transferring the goods of the society, except for the kingdoms of Castile, Aragon, Portugal, and Majorca, to the Knights of St. John. The order was never formally pronounced guilty of the crimes laid to its charge; its abolition was distinctly, in the terms of Clement's bull *Considerantes Dudum*, "non per modum definitivæ sententiæ, cum eam super hoc secundum inquisitiones et processus super his habitos non possemus ferre de jure sed per viam provisionis et ordinationis apostolicæ" (6th May, 1312).

The individual members of the order seem to have been left to the judgment of provincial councils. They were divided into three classes,—(1) those who confessed at once; (2) those who persisted in denial of the charges; (3) those who, having confessed at first, withdrew their confessions later on the plea that they had been extracted by torture. The penalties for the three classes were respectively (1) penitence, (2) perpetual imprisonment, (3) death by fire. The cases of the grand-master, the visitor of France, and the masters of Aquitaine and Normandy were reserved for the pope's decision. Early in 1314 they were forced to make a public confession in Notre Dame, and had already been condemned to perpetual imprisonment when the grand-master and the preceptor of Normandy publicly proclaimed their entire innocence. The king, without consulting the church, had them burnt "in the little island" of the Seine "between the Augustinians and the royal garden."

Question of their guilt or innocence.

The opinion that the monstrous charges brought against the Templars were false and the confessions were only extracted by torture is supported by the general results of the investigation (in almost every country outside France), as we have them collected in Raynouard, Labbe, and Du Puy. In Castile, where the king flung them into prison, they were acquitted at the council of Salamanca. In Aragon, where they held out for a time in their fortresses against the royal power, the council of Tarragona proclaimed in their favor (4th November, 1312). In Portugal the commissioners reported that there were no grounds for accusation. At Mainz the council pronounced the order blameless. At Treves, at Messina, and at Bologna, in Romagna and in Cyprus, they were either acquitted or no evidence was forthcoming against them. At the council of Ravenna the question as to whether torture should be used was answered in the negative except by two Dominicans; all the Templars were absolved,—even those who had confessed through fear of torture being pronounced innocent (18th June, 1310). Six Templars were examined at Florence, and their evidence is for its length the most remarkable of all that is still extant. Roughly speaking, they confess with the most elaborate detail to every charge,—even the most loathsome; and the perusal of their evidence induces a constant suspicion that their answers were practically dictated to them in the process of the examination or invented by the witnesses themselves.[2] In England, where perhaps torture was not used, out of eighty Templars examined only four confessed to the charge of denying Christ, and of these four two were apostate knights. But some English Templars would only guarantee the purity of their own country. That in England as elsewhere the charges were held to be not absolutely proved seems evident from the form of confession to be used before absolution, in which the Templars acknowledged themselves to be defamed in the matter of certain articles that they cannot purge themselves. In England nearly all the worst evidence comes at second or third hand or through the depositions of Franciscans and Dominicans. Yet it can hardly be doubted that the "spuitio super crucem" did form a part of the initiation ceremony. Even the English Templars admitted that the statutes of the order were one and the same all the world over; and there is no setting aside the consistent evidence of almost every French Templar as to his guilt in this matter. Of the other charges the most revolting may have originated in the abuse and misinterpretation of a license primarily intended for military emergencies. Such at least is the form it seems to take in the evidence of John Senand (ap. Mich., ii. p. 137). A debased mind might misinterpret this concession and translate it into coarser words, till (this part of the initiation ceremony being probably conducted in private, as, most certainly, was the spitting on the cross) there might be two formularies current in the order, of which the second was plainly immoral, whereas the first was perfectly harmless unless coupled with a *sous-entendre*. So too with regard to the *spuitio*. One Templar says plainly that he took it for a joke,—*pro trufa:* others regarded it as an imitation of St. Peter's denial; a modern writer has suggested that the custom was intended as a symbol of absolute obedience (ap. Mich., ii. 260). There is little doubt that most members looked upon the ceremony with disgust. Some salved their consciences by the excuse that they were denying Jesus and not Christ; another when shown the crucifix denied his belief in the painted figure. Nearly all declared that they had spat near but not upon the cross, and denied Christ "non corde sed ore." Men who could thus play with their own consciences at their initiation might well, when their lives were in peril, clothe a falsehood in the garb of truth by denying "spuitio super crucem" instead of confessing to "spuitio juxta crucem."

---

[2] See the evidence in full ap. Loiseleur, pp. 172-212.

The other charges stand upon a somewhat similar footing. The power of lay absolution might easily be developed out of the harmless words with which the master or preceptor dismissed his chapter. The cordulæ which Templars were accused of wearing in honor of their idol take a very different appearance as the "zones of chastity" or "belt of Nazareth" worn in accordance with St. Bernard's precept. With regard to the charge of idolatry the evidence is very conflicting. In France and at Fflorence a large proportion of the members confessed to indecent kissing (*oscula inhonesta*) at their initiation; but hardly a single English Templar admitted the charge, and one French witness suggested an almost ludicrous explanation of the rumor. Here also a simple ceremony of respect or humiliation seems to have been expanded into one of shamelessness; but the evidence is too strong to admit of its being explained away, at least in France.

Doctrinal errors.

Not a few witnesses confessed that they had been called upon to declare Christ a false prophet, who suffered for His own sins and not for the race, and to believe only in a superior God of the heavens (*Deum cœli superiorem*). One Florence witness admits that the idol was worshipped as God and Saviour. It was this head, according to one of the witnesses, that could make the order rich and cause the earth to bud and the trees to blossom. A Carcassonne Templar spoke of the idol (Raynouard, 241) as a *friend of God*, who converses with God when he wishes. On such evidence M. Loiseleur holds that the Templars were members of a secret religion, which combined the heretical teachings of the Bogomilians and the Luciferians. The former "the friends of God," believed in a Supreme Deity, whose eldest son Satanael was the creator of our world after his revolt against his father, and whose younger son Jesus was made man to counteract the evil deeds of his brother. They did not venerate the cross, regarding it as the instrument of Christ's passion. The Luciferians, on the other hand, worshipped the eldest son, who had power over all the riches of this world. M. Loiseleur has shown some remarkable coincidences, verbal and otherwise, between the creed of these two sects and that of the Templars, who, according to him, borrowed from the former their belief in the Supreme Deity and from the latter their devotion to the God of this earth. It seems, however, doubtful whether he is justified in combining the several items of such scattered evidence into a complete doctrinal system. His argument might be turned against himself; for, if these heresies were so widely spread in mediæval Europe, are they not for that reason those most likely to be ascribed to an unpopular order?

On the whole it may perhaps be admitted that the charges of "spuitio" and "osculatio inhonesta" were current, at least sporadically, for fifty years before the suppression of the order.[1] They may have become more general in the time of Thomas Beraud, the grand-master (who died 1273), according to the evidence of the preceptor of Aquitaine. On the death of William de Beaujeu (1291) there were two rivals for the office of grand-master,—Hugh de Peraud, the visitor of France, and James de Molai. The latter in 1291, at a general chapter, had declared his intention of extirpating certain practices in the order of which he did not approve[2]; while, if we may trust the French witnesses, the most vigorous initiator according to the new method was Hugh de Peraud. This exactly fits in with the account[3] that the errors were introduced after William de Beaujeu's death. In other words, it is probable that the party of Hugh de Peraud between 1290 and 1307 made a desperate effort to enforce the new ceremonies and the new doctrines throughout France and England. The custom of "spuitio," at all events, was very ancient, and Hugh de Peraud devoted his energies to the propagation of the "osculatio inhonesta." This would explain the omission of all allusion to the latter ceremony when the English Templars were absolved; for they would not confess to a practice of which they were innocent. This theory likewise goes a long way towards interpreting both the confession and the denial of James de Molai and the general acquittal of the Templars in nearly all the councils outside France. (T. A. A.)

TEMPLE.

Meaning.

TEMPLE. The temple is an institution common to religions of natural growth which have reached a certain stage, and in most languages bears a name expressing that it is the house or palace erected by men as a habitation for their god[4] (Greek, *ναός*; Hebrew, *hēkal*, "palace," or *bēth ĕlōhīm*, "house of God;" Latin, *ædes sacræ*). In this connection the term "house of God" has quite a different sense from that which we connect with it when we apply it to a Christian place of worship. A temple is not a meeting-place for worshippers; for many ancient temples were open only to priests, and as a general rule the altar, which was the true place of worship, stood not within the house but before the door. The temple is the dwelling-house of the deity to which it is consecrated, whose presence is marked by a statue or other sacred symbol; and in it his sacred treasures, the gifts and tribute of his worshippers, are kept under the charge of his attendants or priests. Again, a temple implies a sanctuary; but a sanctuary or holy spot does not necessarily contain a temple. A piece of land may be reserved for the deity without a dwelling-house being erected to him upon it, and a sacred tree, stone, or altar, with the holy precinct surrounding it, may be recognized as a place where the worshipper can meet his god and present his offerings, although no temple is attached. Indeed the conception of a holy place, separated from profane use, is older than the beginnings of architecture; and natural objects of worship, such as trees and stones, which need no artificial protection or official keeper, are older than images enshrined under roofs and protected by walls and doors. All antique religion is essentially altar-worship (see SACRIFICE), and for ritual purposes the altar always continued to be the true centre of the sanctuary. But the altar is only a modification of the sacred stone (comp. PRIEST, vol. xix. p. 747), and it has already been observed that, even in later times, the chief altar of a sanctuary stood outside the temple. In the oldest and most primitive forms of religion the sacred stone is at once the place where gifts are offered and the material sign of the presence of the deity; thus the temple with its image belongs to a later development, in which the significance of the sacred stone is divided between the altar outside the door and the idol, or its equivalent, within. But in many very ancient sanctuaries the place of a temple is taken by a natural or artificial grotto (*e.g.*, the Phœnician Astarte grottos, the grotto of Cynthus in Delos), or else the temple is built over a subterranean opening (as at Delphi); and while this may be in part explained as connected with the cult of telluric deities, or the worship of the dead, it seems not unreasonable to think that in their origin cave temples may date back to the time when caves were commonly used as human habitations, that the altar in front of the temple had its prototype in altars at the mouths of sacred caves, which were approached with holy fear and not entered by ordinary worshippers, and that thus some of the main features of the ancient temple were fixed from the first by the analogy of more primitive sanctuaries. The influence of the cave temple seems at least to be undeniable in that widespread type of sanctuary in which besides the court for the worshippers and an outer chamber, there was a dark and mysterious inner room, an adytum or Holy of Holies. This type is found in Egypt (see ARCHITECTURE, vol. ii. p. 340 and plate VII.), among the Semites, as in the temple at Jerusalem and in that of Hierapolis (*De Dea Syr.*, § 31), and also among the Greeks and Romans. In Greece the adytum was not a universal feature, though large temples usually had an antechamber as well as the cella or proper chamber of the god. But, where an oracle was given, or mysteries were celebrated, an adytum was always found, and one of its names was *μέγαρον*, which seems to be a transcription of a Semitic word for a cave (*meghara*). Certain adyta in Greece were actually subterranean; and the association of oracles with caves is well known.

[1] See Mich., ii. 6–11.

[2] Mich., ii. 139, 247.

[3] Mich., ii. 132.

[4] *Templum* properly denotes a spot inaugurated for the observation of auspices by the augurs. But at Rome most *ædes sacræ* were also *templa*, and so the terms came to be used as synonymous.

The architectural features and plan of temples in various parts of the world have been illustrated at length in the article ARCHITECTURE, and need not detain us here, but some further notice of the successive temples at Jerusalem is called for by the unique interest of the subject, while a glance at the topographical problems connected with this holy site is necessary to supplement the article JERUSALEM.

Solomon's temple.

1. *The Temple of Solomon.*—There were temples among the Hebrews before the time of Solomon, whether private, like that of Micah (Judges xvii. 5), or public, like that of Shiloh, where the ark was housed for a time (see TABERNACLE). In this, as in other matters, the Israelites must have learned from the Canaanites, who had large temples in the time of the Judges. The "hold" (vault?) of the temple of El-Berith at Shechem was the place of refuge for a thousand men (Judges ix. 46 *sq.*), and at Gaza there was a vast temple with a roof supported on two middle pillars (Judges xvi. 29). Solomon's enterprise was not therefore absolutely novel, and in point of size his temple can hardly have surpassed those just mentioned. But his subjects were much behind the Canaanites and Philistines in the constructive arts, and as Solomon had to call in the aid of Tyrian craftsmen it cannot be questioned that the design was derived from Tyrian architecture. The general plan, indeed, of the house or "palace" (*hēkal*) of Jehovah, with an adytum (*debīr*, E. V. "oracle"), an outer chamber, and an altar before the door, is, as we have seen, common to many countries, especially in temples which had an oracle, as was the case with Solomon's temple, built to contain the ark. But all the distinctive features are Phœnician, or at least characteristic of the northern Semites, of whose art the Phœnicians were then the leading exponents. For the general arrangements the temple of Hierapolis (Mabbōg), described by Lucian, offers a complete parallel. Like that of Solomon, it faced the east, and had two cellæ and a pronaos. The interior was enriched with gold work. Before the door stood a brazen altar within a walled court. The walled court is a constant feature in the Phœnician and Syrian temples, known to us from their remains or from coins,[1] and the golden decorations, the portico, and the brazen altar appear in the ancient temple of Byblus and in other Phœnician shrines (*C. I. S.*, Nos. 2, 143). The chief motives in the internal decoration of Solomon's temple were the palm tree and the cherub. The former is one of the commonest Phœnician symbols, and the Phœnician associations of the latter are clear from Ezek. xxviii. The cherub, in fact, is only a variety of the sphinx, and the way in which the palm and winged animal figures were combined in Phœnician decoration is shown in a fragment of alabaster preserved in the Louvre and here figured (Fig. 1) after Perrot (*op. cit.*, iii. 131). Two cherubs with outstretched wings stood in the adytum to form a baldachin over the ark. Baldachins over the image or symbol of the deity existed in other temples of the northern Semites (Donaldson, *op. cit.*, pp. 73, 76 *sq.*, 99), and in many Phœnician works of art *e.g.*, on the stele of Byblus) the figure or symbol of a deity is overshadowed by the winged disk (an Assyrian symbol of godhead) arranged as a sort of canopy (Ménant, *Glyptique Oriental*, ii. 231, 238).

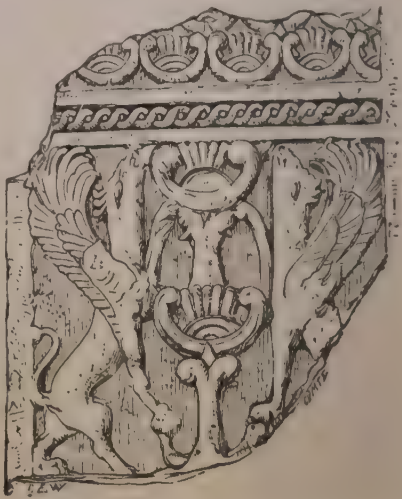

FIG. 1.

The adytum of the temple was a cube of 20 cubits each way; the outer chamber was of the same breadth, but 40 cubits long and 30 high.[2] The portico was of the breadth of the main building and 10 cubits deep. That the two chambers were separated by a solid wall and not by a mere wooden partition may be taken as certain if, with Stade, we understand 1 Kings vi. 31 to say that the doorway of the adytum was pentagonal, *i.e.*, that instead of a horizontal lintel a rude arch of two blocks was introduced to distribute the pressure of the superincumbent wall. In this case it is not likely that the exterior walls of the adytum were carried up to a height of 30 cubits, so as to allow of a continuous roof. The reduction of the dimensions to English feet is approximately determined by the Siloam inscription, which gives a round number of 1200 cubits for a measured length of 1760 feet. The Hebrew cubit, therefore, was the short cubit of antiquity, and for practical purposes may be taken as equal to the Greek cubit of 18 inches, used by Josephus for the measurements of Herod's temple. Thus the roof-beams of the temple had a span of 30 feet, a length sufficient to make it probable that the wooden pillars spoken of in 1 Kings x. 12 (comp. 2 Kings xviii. 16) were employed to support them. The roof of the temple at Gaza rested on pillars, as we have seen, and wooden pillars seem to have been used within the temple at Golgus (Cesnola, *Cyprus*, p. 139), which was smaller than that of Jerusalem. A peculiar feature in Solomon's temple was that all its sides, except the front, were surrounded by three stories (each 5 cubits high) of small chambers, 5 cubits wide on the ground floor, 6 on the first floor, and 7 on the second, the increasing breadth being evidently got by reducing the thickness of the walls by 1 cubit at each floor.[3] Thus, allowing for the walls, the external measurements of the house cannot have been much less than 45 cubits by 90. The aspect of the façade can only be conjecturally determined. Several Phœnician temples, known from coins, show on their façade a high-pitched gable (Byblus, Tripolis), and that of Tripolis has also a flat-roofed wing on each side of the gable and portico, which would answer to the ends of the side chambers in our temple. But perhaps the closest analogy to the frontispiece of Solomon's temple is the often-cited one of the temple at Paphos, of which a representation from a coin is annexed (Fig. 2). Here the portico between the side wings is flanked by two slender towers, and in the end of the nave above the door there are square-topped windows. Solomon's temple had "windows of beams" (or "with horizontal lintels") "framed in," which, as Professor J. H. Middleton observes, is naturally explained on the analogy of the windows between the beams in the wooden gables of Coptic churches. This is the obvious position of openings for light in buildings the type of which was derived from wooden constructions, and we know that the oldest Phœnician temples were, at least in great part, of wood (Utica; Pliny, *H. N.*, xvi. 79; comp. Jos., *C. Ap.*, i. 17, 18, and Solomon's house of the forest of Lebanon). That Solomon's temple had towers cannot be proved, for the height of the porch is not given in Kings, and the 120 cubits of 2 Chron. iii. 4 is obviously an excessive figure, due to a mistake of the writer or of a copyist. But the fact that in Ezekiel's ideal temple the door-posts of the porch are 5 cubits broad makes the existence of slender turrets like those of Paphos on each side of the portal probable. Another feature of Solomon's temple is exactly reproduced at Paphos. On each side of the door the coin shows a fastastic pillar standing free. Solomon erected two such pillars of bronze, 18 cubits high (1 Kings vii. 15 *sq.*), with capitals of "lily work," *i e.*, adorned with lotus flowers, like the Phœnician capital from Cyprus figured by Perrot (*op. cit.*, p. 116). Such twin pillars or twin stelæ in stone are of constant occurrence in Phœnician sacred art, and are still familiar to us as the Pillars of Hercules. In Solomon's temple both the oracle and the outer cella had folding doors. In the second and third temples the inner door was replaced by a vail (*pārōkheth*), and a vail also hung before the outer door (Mal. i. 10; 1 Mac. i. 22, iv. 51; *B. J.* v. 5, § 4 *sq.*). The Chronicler (2 Chron. iii. 14) introduces a vail in the first temple. This feature also seems to be common to the temple with other Semitic shrines comp. *C. I. S.*, No. 86, פרכם, Assyr. *parakku*, Syriac *prakkē*, "shrines," and the Kaaba at Mecca).[1]

[2] The description of the temple in 1 Kings is often obscure and the text is not always sound. Cp. Stade's essay in *Z. f. ATliche Wiss.*, 1883, p. 129 *sq.*

[3] In such small chambers the winding stair (1 Kings vi. 8) can hardly have been more than a vertical post with footholds nailed to it (Prof. J. H. Middleton).

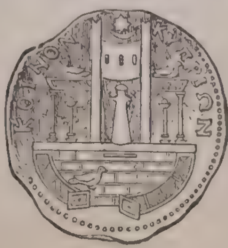

FIG. 2.

The temple had an inner court of its own (1 Kings vi. 36), but the outer or great court (1 Kings vii. 12) was the court of the palace as well as of the sanctuary. Details as to the position of the courts and buildings must be reserved till we speak of the site, but it may be noticed that Jer. xxxvi. 10 speaks of the "higher court," to which the "new gate" of the temple belonged. This new gate in the higher court can hardly be different from the "higher gate" built by Jotham (2 Kings xv. 35), or from the "higher gate" of Benjamin, which, in Jer. xx. 2, is not the city gate of that name, but a gate "in" (not "by" as E. V.) "the house of the Lord." From its name this gate must have been on the north side or at the northeast angle of the temple area, so that the ground rose to the north or northeast. The upper court may be merely the upper part of the great court near the "higher gate" leading to the palace (2 Chron. xxiii. 20), or may be the same as the "new court" of 2 Chron. xx. 5. But one cannot be sure that the Chronicler is not transferring to Jehoshaphat's time a new court of the second temple. We know, however, that the kings of Judah made from time to time considerable changes in and about the temple.

Zerubbabel's temple.

2. *The Temple of Zerubbabel.*—After the captivity an altar of stone took the place of the brazen altar, or rather perhaps of the altar of Ahaz (2 Kings xvi. 10 *sq.*). The altar was erected immediately after the the return (Ezra iii. 2); but the rebuilding of the temple was long delayed, and the work was not completed till 520 B.C. (see HAGGAI). It was much inferior to the first temple in magnificence, though not perhaps in size (Haggai ii. 3). The proposed breadth of 60 cubits and height of 60 cubits spoken of in Ezra vi. 3 would indeed imply that it was larger than the first temple, but in view of the testimony of Haggai (*loc. cit.*) it seems unlikely that these dimensions were realized by Zerubbabel.

The first temple resembled other temples of antiquity in being built to contain a visible symbol of the presence of the deity, namely, the ark, which stood in the inner chamber. In the second temple the adytum was empty, but the idea that the Godhead was locally present in it still found expression in the continuance of the altar service, in the table of showbread (a sort of continual *lectisternium*) that stood in the outer chamber, and above all in the annual ritual of the day of atonement, when the high priest entered the Holy of Holies to sprinkle the blood of the expiatory sacrifice on behalf of the people. Not only in this point but in all others the ritual of the second temple was dominated by the idea of priestly mediation, and the stated sacrifice of the priests on behalf of the people, which replaced the old stated oblations of the kings, became the main feature of the altar service. The first temple was primarily the royal chapel, and the kings did as they pleased in it; the second temple was the sanctuary of the priests, whose chief now became the temporal as well as the spiritual head of the people. In the time of Ezekiel not only laymen but uncircumcised foreigners entered the sanctuary and acted as servants in the sacred offices (Ezek. xliv. 7); in the second temple the laity were anxiously kept at a distance from the holy things, and even part of the court around the altar was fenced off by a barrier, which only the priests were allowed to cross (Joseph., *Ant.*, xiii. 13, § 5). Being no longer hemmed in by the royal buildings, as the first temple had been (Ezek. xliii. 8), its precincts could be expanded to suit the necessities of the enormous host of ministers of various ranks demanded by the growing complexity of the ritual, which, in matters of music and the like was immensely developed as time went on (comp. PSALMS). Herod's temple, with the dependent buildings, was a little city enclosed in its own fortifications. But long before his time the temple was a sort of priestly citadel, the fortress as well as the sanctuary of the hierocracy; and the sacred offerings which flowed to Jerusalem from Jews in all parts of the world were lavishly expended on enlarging and strengthening it (Jos., *B. J.*, v. 5 § 1). The name of Simon II. (*c.* 200 B.C.) is associated in Ecclus. l. 1 *sq.* with important works of fortification on the circuit of the temple. Twice ruined in the wars with the Seleucids, these bulwarks were twice rebuilt, by Judas and Jonathan Maccabæus (1 Mac. iv. 60; ? 1 Mac. vi. 7; Jos., *Ant.*, xiii. 5, § 11). The works were further strengthened by Simon (1 Mac. xiii. 52), and at the time of Pompey's siege (63 B.C.) constituted an almost impregnable fastness, strengthened on its weakest or northern side by great towers and a deep ditch (*Ant.*, xiv. 4, § 2). Twenty-six years later the temple was again besieged by Herod, who, attacking, like Pompey, from the north, had to force three lines of defence,—the city wall and the outer and inner temple (*Ant.*, xiv. 16, § 2).

Of the temple as it was in the Greek or the Hasmonean period we have two descriptions by Hellenistic Jews, Pseudo-Aristæus) comp. SEPTUAGINT) and Pseudo-Hecatæus (Jos., *C. Ap.*, i. 22). In such a matter we may suspect even notorious literary forgers of carelessness and exaggeration rather than of absolute untruth. Pseudo-Aristæus describes the temple as surrounded by a triple circuit of walls more than 70 cubits high, and as further protected by the adjoining Acra, which overlooked the place of sacrifice. Comparing the account of Herod's siege, we may perhaps take the third circuit to be the wall of the town, which is represented as lying below the temple on the same hill. The upper city on the western hill is ignored, which seems to show that the account was written before the Hasmonean period (comp. JERUSALEM, vol. xiii. p. 652), as has been argued on other grounds in SEPTUAGINT. The Acra, which is often mentioned in the history of the Maccabee wars, seems to have been on the same site as the Baris or castle of the Hasmonean priest-princes, where they put on their priestly robes before doing sacrifice (*Ant.*, xv. 11, § 4). That the Baris was close to the temple appears both from this circumstance and from the fact that Antigonus was charged with setting fire to the porticos of the temple during the siege by Herod (*Ant.*, xiv. 16, § 2),—an accusation which would have had no plausibility unless the destruction of the porticos had been useful to isolate the castle. Pseudo-Hecatæus gives the temple precincts a length of 500 feet and a breadth of 100 cubits. The explanation of these numbers will appear in the sequel.

---

[1] Cp. also the vail of Assyrian tissue given by Antiochus to the temple at Olympia (Pausan., v. 12, § 4), which Ganneau (*Quarterly Statement*, April, 1878) boldly identifies with the vail of the temple that Antiochus Epiphanes carried off from Jerusalem (1 Mac., i. 22; Jos., *Ant.*, xii. 5, § 4).

Herod's temple.

3. *The Temple of Herod.*—In the eighteenth year of his reign (20–19 B.C.) Herod the Great began to rebuild the temple and its precincts from the foundation, doubling the old area (*Ant.*, xv. 11; *Bell. Jud.*, i. 21). The works included the reconstruction, on the old site, of the Baris, which now received the name of Antonia, and is generally reckoned by Josephus as forming part of the temple precincts. Apart from the Antonia, the temple area formed a quadrangular plateau supported by retaining walls of great height and strength, and surrounded by porticos. Three of the porticos were double walks, 30 cubits broad, with monolith pillars 25 cubits high, and cedar roofs; the fourth or southern portico (the Stoa Basilica) had four rows of Corinthian pillars and three walks, respectively 30, 45, and 30 cubits in breadth. The middle walk was twice the height of the aisles, and the latter were 50 feet high. As regards the size of this enclosure, we are told by Josephus that the Stoa Basilica was a stadium or 600 feet long (*Ant.*, xv. 11, § 5); and in *Ant.*, xx. 9, § 7, the same length is assigned to the eastern colonnade, which was known as Solomon's Porch (comp. John x. 23; Acts iii. 11 and v. 12), because it, and it alone, rested on an ancient substructure held to be the work of Solomon. The whole circuit of the porticos was therefore 4 stadia,[1] or with the Antonia 6 stadia (*B. J.*, v. 5, § 2). The Antonia lay on the north side (*Ant.*, xv. 11, § 4) and communicated by stairs with the north and west porticos at the northwest angle of the enclosure. Fergusson and others suppose that it touched the temple only at this angle, thence stretching north and west. But in this case the Antonia, which, as we shall see below, lay just north of Wilson's arch, would have been built over the hollow of the Tyropœon valley, a supposition absurd in itself and inconsistent with *B.J.*, v. 5, § 8, which says that it stood on a cliff. Again, the tower 70 cubits high that stood at the southeast angle of the Antonia overlooked the whole temple, just as we know from Pseudo-Aristæus that the old Acra overlooked the altar. But, if the southeast angle of the Antonia had been, as Fergusson supposes, at the northwest angle of the temple porticos, the view from the tower would have been intercepted by the lofty porch in front of the Holy Place. The Antonia, therefore, had its south face along part of the north face of the temple enclosure, and to gain a circuit of 6 stadia for temple and Antonia together we must assign to the latter the length of a stadium from north to south. This is not too much, for Josephus describes it as a little town in itself (*B. J.*, v. 5, § 8).

The Antonia, the porticos, and the space immediately within them (the outer court, or, as modern writers call it, the court of the Gentiles) were not holy ground. But in the middle of the enclosure there was a platform raised 15 cubits above the court of the Gentiles and fenced off by a barrier, with inscriptions, one of which still exists (*Palestine E. F. Quarterly Statement*, 1871, p. 132), forbidding aliens to pass on pain of death. The platform was approached by steps on all sides but the west (*B. J.*, v. 1, § 5, and 5, § 2), and was surrounded by a wall, rising 25 cubits above the inner level, and pierced by four gates on the north side and as many on the south. On the west there was no gate, but on the east—that is, in front of the fane—there were two, one within the other; for the eastern end of the platform was walled off to form a separate court for the women, at a somewhat lower level. One of the northern and one of the southern gates belonged to the court of the women, but it was also entered directly from the east by a very splendid gate of Corinthian brass, much more costly than the others, though they were overlaid with silver and gold. An enormous gate, 40 cubits wide and 50 high (gate Nicanor), connected the women's court with the higher part of the platform, or court of the men of Israel. The beautiful gate of Acts iii. 2 is variously identified with the first or second of these eastern portals. The walls of the platform were lined within with chambers, in front of which ran a splendid colonnade; and the gateways were connected with the colonnade by small lofty halls (*exedræ*), which from without had a towerlike aspect. It is doubtful whether all the gates had *exedræ*; but, on the other hand, there was such a hall also at the west end where no gate opened. In the court of the men—*i.e.*, in the upper and western part of the platform just described—stood the fane or temple proper raised twelve steps above the court. For the ground plan of the Holy Place and the Holy of Holies the ancient dimensions of Solomon's temple were preserved, and the external size demanded by the scale of the surroundings was gained by increasing their height, placing a lofty second story above them, making their walls and those of the surrounding chambers (corresponding to the chambers in the first temple) enormously thick, and placing at the front or east end a porch 100 cubits wide and 100 cubits high. The open doorway of this porch was overlaid with gold, as was also the door of the fane and the wall round it. To the ornament of the entrance belonged also a golden vine with clusters of grapes as big as a man. In front of the fane beneath the steps was the great altar of stone, 50 (or, according to the *Middoth*, 32) cubits square and 15 high; it was ascended by a flight of steps from the south. The part of the court round the fane and the altar was fenced off for the use of the priests, and other Israelites were admitted only when the sacrificial ritual required the presence of the sacrificer.

Besides the descriptions in Josephus, we have for Herod's temple a mass of details and measurements in the Mishnic treatise *Middoth*. Josephus was himself a priest, while the Mishnah was not written till a century after the destruction of the temple, though it uses traditions that go back to Levites who had served in the temple. The two sources differ in many measurements, and the *Middoth* appears to be possessed of detailed traditions only for the inner temple. The state of the evidence is not such as to allow a plan of the temple to be formed with architectural precision. The above account rests almost entirely on Josephus, who, apart from certain exaggerations in detail, gives a satisfactory general account, such as could be written from memory without notes and drawings.

Herod's gigantic and costly structures were still in building, forty-six years after their commencement, when our Lord began His ministry (John ii. 20), and the works were not completed till the procuratorship of Albinus (62–64 A.D.). In 66 the great revolt against Rome broke out, and in August, 70, Jerusalem was taken by Titus and the temple perished in a great conflagration.[1]

---

[1] This measurement (*Ant.*, xv. 11, § 3) has often been taken to refer to Solomon's temple. But this view is not demanded by the words of Josephus, and is inconsistent with the other measurements he gives and with *B. J.*, v. 5, § 1, which states that the plateau was levelled up by Solomon only on the east. This from the lie of the contour lines makes a plateau 600 feet square impossible.. The Mishnah makes the "mountain of the house" a square of 500 cubits, apparently borrowing from Ezekiel.

Topography.

4. *Topography.*—It is not disputed that the site of the temple lay within the great Haram platform (see JERUSALEM), now a Moslem holy place, and it is generally agreed also that the southwest corner of that platform is the southwest corner of Herod's outer plateau, parts of the southern and western retaining walls being confidently ascribed by experts to his age. But if Herod's temple (excluding the Antonia) was only 600 feet square it can have occupied but a small part of the Haram area, which measures about 1500 feet from north to south and 922 feet along the south wall. Moreover, the highest part of the hill, where the Dome of the Rock now stands, must have been outside and north of the temple enclosure. But this affords no good reason to doubt the accuracy of Josephus's measurements in a matter in which his memory could hardly fail him, and where his tendency would be rather to exaggerate than to diminish. There is no evidence that the eastern wall of the Haram is as old as Herod, much less as old as Solomon; for the supposed Phœnician letters found on stones belonging to it are not letters at all, and may be of any date.[2] Moreover, there are various evidences of later building about the east wall of the Haram; the so-called Golden Gate is certainly a later construction, and Justinian's church rested on new substructures to the south and east (Procopius, *De Æd.*, v. 6), which implies an extension eastward of the old platform. And this is confirmed by the fact that in the neighborhood of the southeast angle the platform does not rest on solid substructures such as Josephus speaks of, but on the vaults known as Solomon's stables. Again, though the temple of Solomon lay above the town, there is no evidence that it was on the very top of the hill; on the contrary, buildings of the dimensions given in 1 Kings might have been placed on the hill-top without the need for such great substructures as are spoken of in 1 Kings vii. 10; and we have seen in speaking of the courts of the first temple that the ground appears to have risen to the north, the upper court being on that side.[3]

If we accept the measurements of Josephus we have to break with mediæval tradition, both Moslem and Christian, which associates the Sakhra or rock under the dome on the top of the hill with the sacred site of the Jews. So much weight has been laid on this circumstance by writers of eminence that it is necessary here to go into some particulars and show that earlier tradition goes quite the other way. It is a Talmudic legend that in the Holy of Holies the place of the lost ark was taken by a stone called the "foundation stone." Further this stone was identified with Jacob's stone at Bethel (comp. Rashi on Gen. xxviii. and Breithaupt's notes). Both Mohammedans and Christians transferred these legends to the Sakhra, which the former accordingly venerated as "a gate of heaven" (Ibn 'Abd Rabbih, '*Iḳd*, iii. 369). Mohammedan sources enable us to trace back this identification to the Moslem Jew Wahb ibn Monabbih, who enriched Islam with so many Jewish fables and died a century after Jerusalem was taken by the Arabs (Ṭabarí, i. 571 *sq.*; Ibn al-Fakíh, p. 97 *sq.*). Eutychius, on the other hand, who is the first Christian writer to apply the Jewish legend to the Moslem Sakhra, avers that the tradition was communicated to 'Omar by the Christian patriarch Sophronius on the taking of Jerusalem, and guided the caliph in the choice of a site for his mosque. Eutychius wrote nearly three hundred years after this event; and, though it is known from earlier authorities (Arculphus, Theophanes) that the first Moslem mosque was built on what was pointed out as the site of the temple, it is equally certain, and was known to Eutychius himself, that that mosque lay to the south of the Sakhra (Eutychius, ii. 289), which was not embraced in the precincts of the Moslem sanctuary till the reign of 'Abd al-Malik, who built the dome as an inscription with the date 691 still testifies (*Ibid.*, p. 365). This is confirmed by the excellent Arabian historian Ibn Wáḍiḥ (ii. 311). 'Abd al-Malik's motive was political, as both historians attest; Mecca being in the hands of a rival, he resolved to set up another place of pilgrimage to supplant the Kaaba, and recommended it to the faithful as the point from which the Prophet made his miraculous ascent from Jerusalem to heaven (Ibn Wáḍiḥ, *ut supra*). There is nothing of the Jewish legend here; that, as we have seen, was supplied by Wahb in the next generation, and on his foundation there grew up a mass of other fables for which it is enough to refer to Ibn al-Fakíh, p. 93 *sq.* From all this it may be taken as certain that at the time of 'Omar it was towards the southwest angle of the Haram, on the site of the original mosque, that tradition supposed the temple to have stood; indeed Eutychius is guilty of self-contradiction when he first says that Sophronius indicated the Sakhra to 'Omar as the site on which to build his mosque, and then adds that it was not part of the Moslem sanctuary till a generation later. Finally, the extension of the Haram to the north so as to bring the Dome of the Rock into the centre of the sacred area was the work of 'Abd al-Malik's son Walíd (Eutychius, ii. 373).

Thus far we have met with nothing but confirmation of Josephus's measurements and the site they imply; but there are other topographical indications which supply confirmation more decisive. And first let us compare what is related of the outer gates of Herod's temple with existing remains. On the north was the gate Tadi of the Mishnah, which Josephus mentions only incidentally. This, like the gate Shushan on the east, which he does not mention at all, must have been of minor importance; the chief accesses were necessarily from the lower city to the south and the upper city to the west beyond the Tyropœon valley. The south wall, says Josephus, had gates in the middle (*Ant.*, xv. 11, 5). The Mishnah names them the two gates of Huldah, which may mean "tunnel (weasel-hole) gates." There is a double gate in the substructure of the south wall, 350 feet from the southwest angle, and from it a double tunnel leads up to the platform. This double gate exactly fits Josephus's description. There is also a triple gate, 600 feet from the southwest angle, which those who suppose the wall to have been more than 600 feet long regard as the second Huldah gate. But this view does not give us two gates in the middle of the wall, especially as the old wall cannot have enclosed Solomon's stables. In the west side the Mishnah places one gate (Kiponus), while Josephus recognizes four. But these accounts are at once reconciled if we accept Josephus's measurements. For of his four gates the most southerly is necessarily the one which opened on a flight of steps descending and then reascending across the Tyropœon to the upper city opposite. Now at the southwest corner of the platform there are still remains of a great arch (Robinson's arch), which must have belonged to a bridge connecting the upper city with the south portico of the temple. Thus one of the four gates is fixed. The second gate led to Herod's palace (at the extreme north of the upper city) by means of an embankment crossing the Tyropœon (*Ant.*, xv. 11, § 5). Comparing *B. J.*, ii. 16, § 3, vi. 6, § 2, and v. 4, § 2, we see that the embankment also carried the city wall (the so-called first wall). Of this approach there are remains at Wilson's arch, 600 feet north of Robinson's arch;[4] thus, if Josephus's measurements are correct, the two western accesses were at the extreme ends of the western portico. Josephus's other two gates led to the suburbs outside the first wall, and therefore lay north of Wilson's arch, and were not gates of the temple enclosure proper but of the Antonia, which Josephus habitually reckons as part of the outer temple.[5] Of them the Mishnah would naturally take no account and as naturally it would neglect the gate that led to the palace as being not a public entrance. But further, according to Josephus's account of the whole circumference of the temple with Antonia, the latter extended a stadium north of the northwest angle of the temple portico, *i.e.*, 600 feet north of Wilson's arch; and, if we measure off this distance on a plan of the rock contours and then draw a line at right angles to represent the north face of the Antonia, we find that this line runs across the narrowest part of the saddle from which the temple hill is assailable. The breadth of the Antonia from east to west cannot have been more than about 300 feet if, as is to be presumed, the gate Tadi was opposite the twin gates of Huldah; but with this breadth it would entirely cover the dangerous saddle.

---

[1] On 10 Ab; but Jewish tradition celebrates 9 Ab as the day of the destruction of the temple.

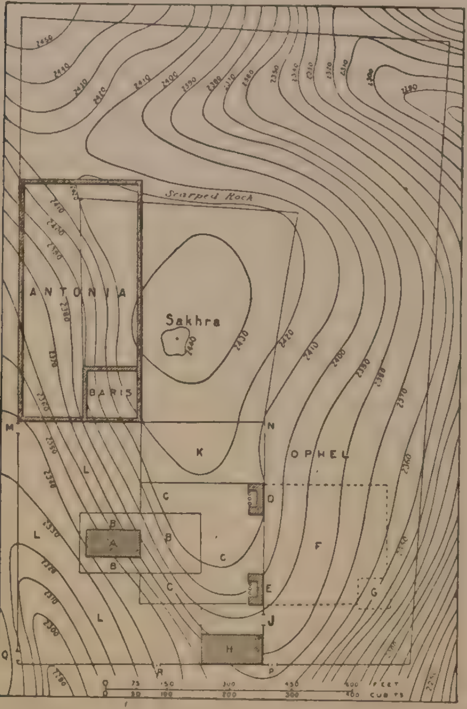
[2] They are represented in the *Recovery of Jerusalem* (p. 143) and in the *Atlas* of plates of Jerusalem published by the Palestine Exploration Fund.

[3] That the temple was built on the threshing-floor of Ornan is naturally assumed by the Chronicler, who likes to minimize the number of old Hebrew sanctuaries; but the old history knows nothing of a consecration of the site before the ark was placed there.

[4] The adjoining remains of ancient buildings unquestionably mark the site of the council hall where the Sanhedrim met, and which was close to the first wall and the temple but outside the latter (*B. J.*, v. 4, § 2; vi. 6, § 3).

[5] One of the suburban gates may be Warren's gate, in the substructures of the Antonia wall, about 170 feet north of Wilson's arch. The other is sometimes identified with Barclay's gate

Every attempt to reconstruct the area and situation of the temple as it was before Herod must be more or less conjectural, and an analysis of the possibilities would take up so much space that it seems better simply to offer a plan which appears to satisfy the main conditions of the problem.



A. Temple. B, B, B. Inner court. C, C, C. Great court. D, E. Porches of the king's house. F. Palace of Solomon. G. Great tower of prison court. H. House of the forest of Lebanon. J. Water gate. K. North court. L, L, L. New space taken in by Herod. MNPQ. Herod's enclosure. NP. Solomon's portico. PQ. Stoa Basilica or royal portico. P. Triple gate. Q. Robinson's arch. R. Double gate (Huldah gates). M. Wilson's arch.

According to this plan the area of the temple enclosure was doubled by Herod, his additions being in the parts where the work of levelling up was heaviest, and where neither the convenience of worshippers nor reasons of defence called on earlier builders to extend the plateau. It is certain that the substructures of the southwest angle, raised to a dizzy height above the Tyropœon, are Herod's (*Ant.*, xv. 11, § 5), and Josephus also speaks of an extension to the north (*B. J.*, v. 5, § 1). But, on the other hand, the Baris already adjoined the temple, a condition which is satisfied by giving the older north court K (corresponding to the new court of Chronicles, and perhaps also to the upper court of the first temple) a length from east to west of 300 feet and a breadth from north to south of 150. The old east face of the plateau is, as Josephus says, 600 feet long, but this length was gained after the time of Nehemiah by taking in the site of the armory or house of the forest of Lebanon (H) and the street in front of the water gate (J). For the proof that the water gate stood at a re-entrant angle between the retaining walls of the armory and the palace and faced east as shown in the plan reference must be made to an article in the *Journal of Philology* (vol. xvi.). The rocky boss between these two walls was in Nehemiah's time surrounded by an outwork, which to the north joined the wall of Ophel,—that is, of the swelling mass of hill which lies out to the northeast of the palace. From the lower city (south of the Haram area) a stair near the wall led up to the plateau H (Neh. iii. 19; xii. 37). The armory was 150 feet long and 75 broad; the plan allows the same dimensions for the open space within the water gate. The great court C, C, C is arranged in accordance with 1 Kings vii. 12, in such a way that it is at once the court of the palace and that of the temple, enclosing the inner court B. The dimensions of the inner court are not given in 1 Kings, but as the temple was twice the size of the tabernacle the court was probably also double the court of the tabernacle. This gives a length of 300 feet and a breadth of 150, as in the plan. The part of the court in front of the temple is 150 feet square, which agrees with the dimensions given in Ezek. xl. 23, 27. The great court is a square of 300 feet. This gives room on the east face for two porches D and E leading to the palace and each 75 feet long. Both porches are described in 1 Kings vii. 6, 8, and the dimensions of one are given. It is also expressly stated that the porch was before (*i.e.*, on the east side of) the pillars that decorated its front, and that it led into the inner court of the palace, so that the arrangement in the plan is fully justified. In the time of Jeremiah (xxxviii. 14) there were three entries from the palace to the temple; the third was probably into the north court, the palace having been extended northwards. It is evident that before the time of Herod the palace had disappeared. It was on a lower level than the temple, and when it was cleared away the great substructures on the line PE stood out as the boundary of Solomon's building. North of E the substructures were less considerable, the rock at the north end of this porch being but 20 feet under the present level of the plateau. In Herod's time, as can be seen at Robinson's arch, the level of the plateau was the same as at present (2420 feet), but in older times there was a fall between the upper and lower court, and K was probably 10 feet above C, C, C. In that case D was on the natural level of the ground, while (unless the great court was on two levels) E stood on a retaining wall 10 feet high at the north end of the porch and nearly twice as lofty at the south end. The plan shows the temple thrown out on very lofty substructures, so as to be practically inaccessible on all sides and overhang the Tyropœon in the most striking way.[1] The whole group of buildings formed a complete defence to the city of David on its northern or vulnerable side It will be observed that in Herod's temple the Huldah gates at R led directly to the altar, the position of which seems never to have been changed, and also that the plan explains the statement of Hecatæus that the temple was 150 feet broad. His length of 500 feet from east to west is 50 feet too much unless he includes some remains of the old palace. The Baris is shown as standing on the southwest corner of the existing platform of the Dome of the Rock.

A word may be said in conclusion on the ancient

---

between Wilson's arch and Robinson's arch. But this would not lead into the suburb.

[1] It ought, however, to be observed that the contour lines in and near B, B, B are almost purely conjectural.

line of wall to the west of the temple, which, as has been shown from Neh. iii. in the article **Jerusalem**, ran along the eastern side of the Tyropœon. A bridge connected the temple with the upper city in the time of the later Hasmoneans, and, as the palace (on the site of Herod's palace) and the Baris were the points which it was most important to connect, it no doubt corresponded to the northern bridge already spoken of, at Wilson's arch M. But at that date it must have led, not directly to the temple, but to a lower point on the slope south of the Baris. In Nehemiah's time there was no bridge, but the gate of Ephraim probably corresponded to the east end of the bridge near the southwest angle of the Baris. In that case the wall, as is natural, ran close under the western substructures of the temple and probably served as a buttress to them in the part of its course south of the gate of Ephraim, which in Neh. xii. 38 is called "the broad wall." The throne of the Persian governor, beside the gate of Ephraim (see **Jerusalem**, vol. xiii. p. 651), stood so close to the Baris that we may conclude that there was already a castle on its site, held for the great king. The position assigned to the gate of Ephraim, which, according to 2 Kings xiv. 13, was 600 feet from the corner gate, where the north wall of the city joined the west wall, suits the fact that a line drawn east and west 600 feet north of Wilson's arch coincides with the line of scarped rock marked on the plan. Here, therefore, the old north wall ran, with the great fosse filled up by Pompey. This wall figures also in Herod's siege, but seems to have been destroyed by him.

Literature.—The literature of the subject is immense. The results of modern surveys and diggings are given in the Palestine Exploration Fund volume on *Jerusalem* (London, 1884) and in the accompanying *Atlas*. Of other books it may suffice to name De Vogué, *Le Temple de Jérusalem* (fol., Paris, 1864); Fergusson, *Topography of Jerusalem* (8vo, London, 1847); Id. *The Temples of the Jews* (4to, London, 1878); Thrupp, *Antient Jerusalem* (8vo, Cambridge, 1855); Lewin, *The Siege of Jerusalem by Titus* (8vo, London, 1863); and Perrot and Chipiez, *Histoire de l'Art* (Paris, 1887).

(W. R. S.)

TEMPLE, Sir William (1628–1699) English statesman, diplomatist, and author, was born in London in 1628. He came of an old English family, but of the younger branch of it, which had for some time been settled in Ireland. He was the eldest son of Sir John Temple, master of the rolls in that country. His mother was Mary Hammond, sister of a well-known Tory divine. Temple received a liberal education, calculated to produce that moderation of judgment for which he was afterwards remarkable. He was first a pupil of his uncle Dr. Hammond, after which he went to the grammar-school at Bishop Stortford, and then to the Puritan college of Emmanuel at Cambridge, where he came under the influence of Cudworth. At the commencement of the civil troubles his father embraced the popular cause and was deprived of his office. Coming to England, he sat in the Long Parliament as member for Chichester, and was one of the recalcitrant members turned out by Colonel Pride. Before this event happened his son had left Cambridge, without taking a degree, and in 1647 started to travel abroad. In the Isle of Wight, while on his way to France, he fell in with Dorothy Osborne, and won her affections. Her father, Sir Peter Osborne, was governor of Guernsey and a Royalist. Her family were naturally opposed to the match, and threw difficulties in the way, which hindered its consummation for seven years. During this period Temple travelled in France, Spain, Holland, and other countries, gaining knowledge of the world and keeping up a constant correspondence with his betrothed. At length, apparently in 1654, the difficulties were surmounted and the marriage took place. In 1655 Temple and his wife went to Ireland. The next five years were spent in the house of Sir John Temple, who had made his peace with Cromwell, and had resumed his official position. His son took no part in politics, but lived the life of a student and a country gentleman.

The accession of Charles II. rescued Temple like many others, from obscurity. In 1660 he sat in the convention parliament at Dublin as member for Carlow, and he represented the same county along with his father in the regular parliament that followed. After a short visit to England in 1661, as commissioner from the Irish parliament, he finally removed thither in 1663. There he attached himself to Arlington, secretary of state, and two years later received his first employment abroad. It was in March, 1665, that the disastrous war with the United Netherlands began. Charles II. was anxious to obtain allies, especially as Louis XIV. was taking up a hostile attitude. At this juncture the bishop of Münster sent an envoy to England, offering to attack the Dutch if the English Government would supply the means. Temple was sent over to negotiate a treaty, and in this business gave evidence not only of the diplomatic skill but of the peculiar candor and frankness for which he was afterwards so distinguished. He was successful in making the treaty, but it was rendered ineffectual by the declaration of war by France, the threats of Louis, and the double-dealing of the prelate, who, after receiving a great part of the subsidy, made a separate peace with the Netherlands. As a reward for his services Temple was created a baronet, and in October, 1665, became the English representative at the viceregal court at Brussels. While the war continued, Temple's duties consisted chiefly in cultivating good relations with Spain, which was a neutral in the quarrel between England and the Dutch, but was threatened by the claims of Louis XIV. on the Spanish Netherlands. Louis's designs became apparent in the spring of 1667, when he marched an army into Flanders. This event was one of those which led to the peace of Breda, and to the subsequent negotiations, which are Temple's chief title to fame. The French conquests were made at the expense of Spain, but were almost equally dangerous to the United Netherlands, whose independence would have been forfeited had Louis succeeded in annexing Flanders. While the French were taking town after town, Temple made a journey into Holland and visited De Witt. The friendship established and the community of views discovered during this interview facilitated the subsequent negotiations. Temple had for some time pressed on his Government the necessity of stopping the French advance, and had pointed out the way to do so, but it was not till December, 1667, that he received instructions to act as he had suggested. He at once set out for The Hague, and in January, 1668, a treaty was made between England and the United Netherlands, which, being joined shortly afterwards by Sweden, became known as the Triple Alliance. It was a defensive treaty, made against the encroachments of France. Whether we regard the skill and celerity with which the negotiations were conducted or the results of the treaty, the transaction reflects great credit on Temple. The French king was checked in mid-career, and, without a blow being struck, was obliged to surrender almost all his conquests. Pepys records public opinion on the treaty by saying that it was "the only good public thing that hath been done since the king came into England."

Unfortunately the policy thus indicated was but short-lived. In taking up a hostile attitude towards France Charles's object had apparently been only to raise his price. Louis took the hint, increased his offers, and two years later the secret treaty of Dover reversed the policy of the Triple Alliance. Meanwhile Temple had developed the good understanding with the Dutch by contracting a commercial treaty with them (February, 1668), and had acted as English plenipotentiary at Aix-la-Chapelle, where peace between France and Spain was made in May, 1668. Shortly afterwards he was appointed ambassador at The Hague. Here he lived for two years on good terms both with De Witt and with the young prince of Orange, afterwards William III. The treaty of Dover led to Temple's recall; but the plot was not yet ripe, and Temple nominally held his post for another year. He perceived, however, that his day was over and retired to his house at Sheen. In June, 1671, he received his formal dismissal. The war with the Netherlands broke out next year, and was almost as discreditable to England as that of 1665. Want of success and the growing strength of the opposition in parliament forced Charles to make peace, and Temple was brought out of his retirement to carry through the change of front. After a negotiation of three days, carried on through the medium of the Spanish ambassador, the treaty of Westminster was made (February, 1674). As a recognition of his services Temple was now offered the embassy to Spain. This he declined, as well as the offer of a far more important post, that of secretary of state, but accepted instead a renewal of his embassy to The Hague, whither he went in July, 1674. In the March following he was nominated ambassador to the congress at Nimeguen; but, owing to the tortuousness of Charles's dealings, it was not till July, 1676, that he entered that town. The negotiations dragged on for two years longer, for Charles was still receiving money from France, and English mediation was no more than a ruse. In the summer of 1677 Temple was summoned to England and received a second offer of the secretaryship of state, which he again declined. In the autumn of the same year he had the satisfaction of removing the last difficulties which hindered the marriage of William and Mary, an event which seemed to complete the work of 1668 and 1674. Louis still remaining obstinate in his demands, Temple was commissioned in July, 1678, to make an alliance with the states, with the object of compelling France to come to terms. This treaty was instrumental in bringing about the general pacification which was concluded in January, 1679.

This was Temple's last appearance in the field of diplomacy; but his public life was not yet over. A third offer of the secretaryship was made to him; but, unwilling as ever to mix himself up with faction and intrigue, he again declined. He did not, however, withdraw from politics; on the contrary, he was for a short time more prominent than ever. The state was passing through a grave crisis. Political passion was embittered by religious fanaticism. Parliament was agitated by the popish plot, and was pressing on the Exclusion Bill. The root of all the mischief lay in the irresponsibility of the cabinet to parliament and its complete subservience to the crown. To remedy this, Temple brought forward his plan for a reform of the privy council. This body was to consist of thirty members, half of whom were to be the chief officers of the crown, the other half being persons of importance, lords and commoners, chosen without reference to party. Special care was taken to select men of wealth, which Temple considered as the chief source of political influence. By the advice of this council the king promised to act. The parliament, it was supposed, would trust such a body, and would cease to dictate to the crown. The scheme was accepted by the king, but was a failure from the outset. Intended to combine the advantages of a parliament and a council, it created a board which was neither the one nor the other. The conduct of affairs fell at once into the hands of a junta of four, of whom Temple was at first one, and the king violated his promise by dissolving parliament without asking the advice of the council. Temple retired in disgust to his villa at Sheen, and appeared only occasionally at the council, where he soon ceased to exercise any influence. In 1680 he was nominated ambassador to Spain, but stayed in England in order to take his seat in parliament as member for the university of Cambridge. He took no part in the debates on the great question of the day, and acting on the king's advice declined to sit in the parliament of 1681. Early in that year his name was struck off the list of the council, and henceforward he disappeared from public life. He continued to live at Sheen till 1686 when he handed over his estate there to his son, the only survivor of seven children, and retired to Moor Park in Surrey. When William III. came to the throne Temple was pressed to take office, but refused. His son became secretary at war, but committed suicide immediately afterwards. Sir William, though occasionally consulted by the king, took no further part in public affairs, but occupied himself in literature, gardening, and other pursuits. It should not be omitted that Swift lived with him as secretary during the last ten years (with one short interval) of his life. Temple died at Moor Park on 27th January, 1699.

Temple's literary works are mostly political, and are of considerable importance. Among them may be mentioned *An Essay on the Present State and Settlement of Ireland* (1668); *The Empire, Sweden*, etc., a survey of the different Governments of Europe and their relations to England (1671); *Observations upon the United Provinces* (1672); *Essay upon the Original and Nature of Government* (1672); *Essay upon the Advancement of Trade in Ireland* (1673). Some of these were published in the first part of his *Miscellanea* (1679). In the same year apparently his *Poems* were privately printed. In 1683 he began to write his *Memoirs*. The first part, extending from 1665 to 1671, he destroyed unpublished; the second, from 1672 to 1679, was published without his authority in 1691; the third, from 1679 to 1681, was published by Swift in 1709. In 1692 he published the second part of his *Miscellanea*, containing among other subjects the essay *Upon the Ancient and Modern Learning*, which is remarkable only as having given rise to the famous controversy on the "Letters of Phalaris." His *Introduction to the History of England*, a short sketch of English history to 1087, was published in 1695. Several collections of his letters were published by Swift and others after his death.

His fame rests, however, far more on his diplomatic triumphs than on his literary work. His connection with domestic affairs was slight and unsuccessful. He was debarred both by his virtues and his defects,—by his impartiality, his honesty, and his want of ambition,—from taking an active part in the disgraceful politics of his time. But in the foreign relations of his country he was intimately concerned for a period of fourteen years, and in all that is praiseworthy in them he had a principal hand. He cannot be called great, but he will be remembered as one of the ablest negotiators that England has produced, and as a public servant who, in an unprincipled age and in circumstances peculiarly open to corruption, preserved a blameless record.

See *Life and Works of Sir William Temple*, 2 vols. fol., 1720; 2d ed., with Life by Lady Giffard, 1731; a more complete edition, including the *Letters*, was published in 4 vols. 8vo, 1814; Burnet, *History of his own Time;* Courtenay, *Memoirs of the Life*, etc., *of Sir William Temple*, 2 vols., 1836; Macaulay, *Essay on Sir William Temple.* (G. W. P.)

TENANT. See Landlord and Tenant.

TENASSERIM, a division of the province of British Burmah, lying between 9° 30′ and 19° 30′ N. lat. and 95° 50′ and 99° 30′ E. long. It has an area of 46,730 square miles and comprises the seven districts of Moulmein town, Amherst, Tavoy, Mergui, Shwagyin, Toungoo, and Salwin, which formed the tract south of Pegu conquered from Burmah in 1826, and were for many years generally known as the Tenasserim provinces. The southern extremity of the division approaches the insular region of Malaysia, and it is fringed along its entire western coast by a number of islands, forming in the north the Moscos and in the south the Mergui Archipelago. The eastern frontier is formed by a mountain range 5000 feet high, which acts as a water-parting between the Tenasserim and the Siamese river systems.

The population of the division in 1881 was 825,741 (437,900 males and 387,841 females). By religion Hindus numbered 23,145, Mohammedans 24,786, Christians 28,315, Buddhists 698,304, and Nat worshippers 51,160. The cultivated area in 1885–6 was returned at 729,251 acres. The gross revenue in the same year was £184,162 [$895,027.32], of which the land-tax yielded £107,631 [$523,086.66].

TENBY, a municipal and parliamentary borough and watering-place of Pembrokeshire, South Wales, is finely situated on a long and narrow promontory of limestone rock, washed on three sides by the sea, on the west side of Carmarthen Bay, and on a branch of the South Wales Railway, 10 miles east of Pembroke and 274 west of London (by rail). Its chief attractions as a watering-place are its picturesque appearance, its antiquarian remains, its equable and salubrious climate, and its wide stretch of firm sands. There are considerable remains of the old fortifications of the town, dating originally from the Norman Conquest, and repaired by Elizabeth, whose initials with the date 1588 are inscribed on a stone near the fine southwest gate, which with the southwest and northwest walls is in very good preservation. The remains of the castle on a lofty rock at the extremity of the promontory include the keep, a circular bastion overhanging the cliffs, and portions of the outer wall. Within the grounds, which are laid out in walks, there is a local museum; and on the summit of the hill is the Welsh memorial to the Prince Consort, a statue of Sicilian marble (1865). Opposite the castle, about 100 yards distant and accessible on foot at low water, is St. Catherine's Island, on which is a strong fort begun in 1868, forming one of the land defences of Pembroke dockyard. The parish church of St. Mary is a large and beautiful building, showing every variety of style from the Norman of the 12th to the Tudor of the late 16th century; it has a massive tower with a spire rising to a height of 152 feet. In the north aisle are some mediæval altar tombs and in the south aisle one of the early Tudor period. The fisheries of Tenby, for which the place was noted at a very early period, are still of importance. The trade of the port is inconsiderable. Steamers, however, ply to Bristol, Cardiff, Ilfracombe, and Weston-super-Mare. In the neighborhood there are extensive limestone quarries. The population of the municipal and parliamentary borough (area 640 acres) in 1871 was 3810, and in 1881 it was 4750. In summer it is augmented by more than a half.

Tenby has the same derivation as Denbigh in North Wales. Anciently it was called Dynbych-y-Pyscod, the "precipice of fishes." The importance of the town dates from the settlement of the Flemings in the reign of Henry I. In 1150 Cadell, eldest son of Rhys ab Gryffith, was slain by the people of Tenby, in revenge for which the castle was taken and the town devastated by his two brothers, Meredith and Rhys. During the Wars of the Roses the fortifications were restored and strengthened by Jaspar, earl of Pembroke. They were again greatly strengthened by Elizabeth in apprehension of the landing of the Spaniards. At the beginning of the Civil War the town and castle were garrisoned for the king, but in 1644 it surrendered to the Parliamentarians after a siege of three days. Its privileges were extended by Humphrey, duke of Gloucester, who made the mayor an independent justice, and by Henry IV., Henry VI., Elizabeth, and Charles I. It is now governed by the Municipal Act, and the corporation are the sanitary authority. Since the 27th of Henry VIII. it has formed part of the Pembroke district of boroughs for parliamentary representation.

TENCH, the *Tinca tinca* of naturalists, is one of the commonest and most widely spread freshwater fishes of Europe. It is generally distributed in all suitable localities throughout England, but is limited to a few lakes and ponds in the south of Scotland and in Ireland. As the tench is of comparatively uncommon occurrence in unenclosed waters, its place among the indigenous fishes of Great Britain has been denied, and it has been supposed to have been introduced from the Continent. In central Europe, however, where it is undoubtedly indigenous, it thrives best in enclosed, preserved waters, with a clayey or muddy bottom and with an abundant vegetation; it avoids clear waters with stony ground, and is altogether absent from rapid streams. The tench belongs to the family of carps (*Cyprinidæ*), and is distinguished from the other members of that family by its very small scales, which are deeply embedded in a thick skin, whose surface is as slippery as that of an eel. All the fins have a rounded outline; the short dorsal fin is without a spine, but the males possess a very thick and flattened outer ray in the ventral fins. The mouth is rather narrow and provided at each corner with a very small barbel. Tench if kept in suitable waters are extremely prolific, and as they grow within a few years to a weight of 3 or 4 ℔, and are then fit for the table, they may be profitably introduced into ponds which are already stocked with other fishes, such as carp and pike. They live on small animals or soft vegetable substances, which they root up from the ground. The albino variety especially, which is known as the "golden tench," can be recommended for ornamental waters, as its bright orange colors render it visible for some distance below the surface of the water. This variety, which seems to have been originally bred in Silesia, is not less well-flavored than the normally colored tench, and grows to the same size, viz., to 6 and even 8 ℔.

Tench (*Tinca tinca*).

TENDER. See PAYMENT.

TENERIFFE. See CANARY ISLANDS, vol. iv. p. 702.

TENIERS, DAVID (1610–1690), the younger, a Flemish painter, almost ranking in celebrity with Rubens and Van Dyck, was born in Antwerp on 15th December, 1610. His father, David Teniers the elder (1582–1649), whose style he followed with a vastly superior power of conception, had been a pupil of Elsheimer in Rome and of Rubens in Antwerp. Besides these influences, we can also distinctly trace that of Adrian Brouwer at the outset of his career. Although the young painter's general system often reminds us of Rubens, several of his works also betray a vivid recollection of Brouwer in type as well as general arrangement. There is no evidence, however, that either Rubens or Brouwer interfered in any way with Teniers's education, and Smith may be correct in supposing that the admiration which Brouwer's pictures at one time excited alone tempted the younger artist to imitate them. The only trace of personal relations having existed between Teniers and Rubens is the fact that the ward of the latter, Anne Breughel, the daughter of John (Velvet) Breughel, married Teniers in 1637. Admitted as a "master" in the guild of St. Luke in 1632, Teniers had even before this made the public acquainted with his works. The Berlin museum possesses a group of ladies and gentlemen dated 1630. No special signature positively distinguishes these first productions from those of his father, and we do not think it correct to admit with some writers that he first painted religious subjects. Dr. Bode, in a most remarkable study of Brouwer and his works, expresses the opinion that Tenier's earliest pictures are those found under the signature "Tenier" (with the omission of the final *s*). Tenier is in reality a Flemish version of a thoroughly Walloon name, "Taisnier," which the painter's grandfather, a mercer, brought with him when he came from Ath in 1558, and

Bode's supposition is greatly strengthened by the circumstance that not only David the elder but his brother Abraham and his four sons were all inscribed as "Tenier" in the ledgers of the Antwerp guild of St. Luke. Some really first-rate works —the Prodigal Son and a group of Topers in the Munich gallery, as well as a party of gentlemen and ladies at dinner, termed the Five Senses, in the Brussels museum—with the above signature are remarkable instances of the perfection attained by the artist when he may be supposed to have been scarcely twenty. His touch is of the rarest delicacy, his color at once gay and harmonious. Both Waagen and Smith express the opinion that the works painted from 1645 to 1650 speak most highly of the master's abilities. We may venture to add that a considerable number of earlier productions would have been sufficient to immortalize his name. He was little over thirty when the Antwerp guild of St. George enabled him to paint the marvellous picture which ultimately found its way to the Hermitage Gallery in St. Petersburg,—the Jubilee Meeting of the Civic Guards, in honor of their old commander, Godfrey Sneyders. Correct to the minutest detail, yet striking in effect, the scene, under the rays of a glorious sunshine, displays an astonishing amount of acquired knowledge and natural good taste. This painting, one of forty among many of the master's earlier and later productions,[1] leads us to mention another work of the same year (1643), now in the National Gallery, London, (No. 952), an equally beautiful repetition of which, dated 1646, belongs to the duke of Bedford. A hundred and fifty figures are resting after a pilgrimage to some holy shrine or some miraculous well. The hungry travellers are waiting for the meal which is being prepared for them in several huge caldrons. Truth in physiognomy, distribution of groups, the beautiful effect of light and shade, command our warmest admiration. A work like this, says Waagen, stamps its author as the greatest among painters of his class. That, however, a subject of the kind should have been accepted as a "feast" (see the National Gallery *Catalogue*) may tend to prove how little, from the first, Teniers thought of dramatizing. Frankness in expression and freedom in attitude certainly guided his preference in the choice of a model, and we may even suppose him to have occasionally exaggerated both. He seems anxious to have it known that, far from indulging in the coarse amusements of the boors he is fond of painting, he himself lives in good style, looks like a gentleman, and behaves as such. He never seems tired of showing the turrets of his château of Perck, and in the midst of rustic merry-makings we often see his family and himself received cap in hand by the joyous peasants. We may also observe that he has a certain number of favorite models, the constant recurrence of which is a special feature of his works. We even meet them in a series of life-size portrait-like figures in the Doria Pamphili Gallery in Rome,[2] as well as in a picture belonging to Mr. H. R. Hughes, and the man here represented as a fishmonger is unmistakably the painter's brother, Abraham Teniers, judging from the portrait Edelinck has left us of this artist.

Teniers was chosen by the common council of Antwerp to preside over the guild of painters in 1644. The archduke Leopold William, who had assumed the government of the Spanish Netherlands, being a great lover of art, employed Teniers not only as a painter but as keeper of the collection of pictures he was then forming. With the rank and title of "ayuda de camara," Teniers took up his abode in Brussels shortly after 1647. Immense sums were spent in the acquisition of paintings for the archduke. A number of valuable works of the Italian masters, now in the Belvedere in Vienna, came from Leopold's gallery after having belonged to Charles I. and the duke of Buckingham. De Bie (1661) states that Teniers was some time in London, collecting pictures for the duke of Fuensaldaña, then acting as Leopold's lieutenant in the Netherlands. Paintings in Madrid, Munich, Vienna, and Brussels have enabled art critics to form an opinion of what the imperial residence was at the time of Leopold, who is represented as conducted by Teniers and admiring some recent acquisition. No picture in the gallery is omitted, every one being inscribed with a number and the name of its author, so that the *ensemble* of these paintings might serve as an illustrated inventory of the collection.[3] Still more interesting is a canvas, now in the Munich gallery, where we see Teniers at work in a room of the palace, with an old peasant as a model and several gentlemen looking on. When Leopold returned to Vienna, Tenier's task ceased; in fact the pictures also travelled to Austria, and a Flemish priest, himself a first-rate flower painter, Van der Baren, became keeper of the archducal gallery. Teniers nevertheless remained in high favor with the new governor-general, Don Juan, a natural son of Philip IV. The prince was his pupil, and De Bie tells us he took the likeness of the painter's son. Honored as one of the greatest painters in Europe, Teniers seems to have made himself extremely miserable through his aristocratic leanings. Shortly after the death of his wife in 1656 he married Isabella de Fren, daughter of the secretary of the council of Brabant, and strove his utmost to prove his right to armorial bearings. In a petition to the king he reminded him that the honor of knighthood had been bestowed upon Rubens and Van Dyck. The king at last declared his readiness to grant the request, but on the express condition that Tenier should give up selling his pictures. The condition was not complied with; but it may perhaps account for the master's activity in favor of the foundation in Antwerp of an academy of fine arts to which artists alone should be admitted, whereas the venerable guild of St. Luke made no difference between art and handicraft: carvers, gilders, bookbinders, stood on an even footing with painters and sculptors, however great their talent.[4] There were great rejoicings in Antwerp when, on 26th January, 1663, Teniers came from Brussels with the royal charter of the academy, the existence of which was due entirely to his personal initiative.

Teniers died in Brussels on 25th April, 1690.[5] A picture in the Munich gallery (No. 906), dated 1680, represents him as an alchemist, oppressed with a burden of age beyond his years. From this date we hear more of his doings as a picture-dealer than as a painter, which most probably gave birth to the legend of his having given himself out as deceased in order to get higher prices for his works. David, his eldest son, a painter of talent and reputation, died in 1685. One of this third Teniers's pictures—St. Dominic Kneeling before the Blessed Virgin, dated 1666—is still to be found in the church at Perck. As well as his father, he contributed many patterns to the celebrated Brussels tapestry looms. Cornelia, the painter's daughter, married John Erasmus Quellin, a well-known artist (1634–1715).

Smith's *Catalogue Raisonné* gives descriptions of over 700 paintings accepted as original productions of Teniers. Few artists ever worked with greater ease, and some of his smaller pictures—landscapes with figures—have been termed

---

[1] The Hermitage *Catalogue* ascribes to Abraham Teniers the portrait of a bishop. This painting is, however, by David, and represents the celebrated bishop of Ghent, Anthony Triist, with his brother Francis, a Franciscan monk.

[2] Under the name of Weeninx.

[3] It was not until recently that the MS. inventory of this collection was discovered among the papers of the prince of Schwartzenberg in Vienna. It was published in 1883 by Adolf Berger. In 1658 Teniers published 243 etchings after the best Italian works of Leopold William's collection, which with the portraits of the archduke and Teniers, were brought together as a volume in 1660, under the title *El Teatro de Pinturas*.

[4] The separation was only obtained in 1773.

[5] The date is often wrongly given as 1694 or 1695.

"afternoons," not from their subjects, but from the time spent in producing them. The museums in Madrid, St. Petersburg, Vienna, Munich, Dresden, Paris, London, and Brussels have more than 200 pictures by Teniers. In the United Kingdom 150 may be found in private hands, and many other examples are to be met with in private collections throughout Europe. Although the spirit of many of these works is as a whole marvellous, their conscientiousness must be regarded as questionable. Especially in the later productions we often detect a lack of earnestness and of the calm and concentrated study of nature which alone prevent expression from degenerating into grimace in situations like those generally depicted by Teniers. His education, and still more his real and assumed position in society, to a great degree account for this. Brouwer knew more of taverns; Ostade was more thoroughly at home in cottages and humble dwellings; Teniers throughout triumphs in broad daylight, and, though many of his interiors may be justly termed masterpieces, they seldom equal his open-air scenes, where he has, without constraint, given full play to the bright resources of his luminous palette. In this respect, as in many others, he almost invariably suggests comparisons with Watteau. Equally sparkling and equally joyous, both seem to live in an almost ideal world, where toil, disease, and poverty may exist, but to be soon forgotten, and where sunshine seems everlasting. But his subjects taken from the Gospels or sacred legend are absurd. An admirable picture in the Louvre shows Peter Denying his Master, next to a table where soldiers are smoking and having a game at cards. He likes going back to subjects illustrated two centuries before by Jerome Bosch—the Temptation of St. Anthony, the Rich Man in Hell, incantations, and witches—for the simple purpose of assembling the most comic apparitions. His villagers drink, play bowls, dance, and sing; they seldom quarrel or fight, and, if they do, seem to be shamming. His powers certainly declined with advancing age; the works of 1654 begin to look hasty. But this much may be said of Teniers, that no other painter shows a more enviable ability to render a conception to his own and other people's satisfaction. His works have a technical freshness, a straightforwardness in means and intent, which make the study of them most delightful; as Sir Joshua Reynolds says, they are worthy of the closest attention of any painter who desires to excel in the mechanical knowledge of his art.

As an etcher Teniers compares very unfavorably with Ostade, Cornelis, Bega, and Dusart. More than 500 plates were made from his pictures; and, if it be true that Louis XIV. judged his "baboons" (*magots*) unworthy of a place in the royal collections, they found admirable engravers in France—Le Bas and his scholars—and passionate admirers. The duke of Bedford's admirable specimen was sold for 18,030 livres (£1860) [$9,039.60] in 1768. The Prodigal Son, now in the Louvre, fetched 30,000 livres (£3095) [$15,041.70] in 1776. Smith's highest estimates have long since been greatly exceeded. The Archers in St. Petersburg he gives as worth £2000 [$9720]. The Belgian Government gave £5000 [$24,300] in 1867 for the Village Pastoral of 1652, which is now in the Brussels museum; and a picture of the Prodigal Son, scarcely 16 by 28 inches, fetched £5280 [$25,660.80] in 1876.

Although Van Tilborgh, who was a scholar of Teniers in Brussels, followed his style with some success, and later painters often excelled in figure-painting on a small scale, Teniers cannot be said to have formed a school. Properly speaking, he is the last representative of the great Flemish traditions of the 17th century.

TENIMBER. See Timor Laut.

TENISON, Thomas (1636–1715), archbishop of Canterbury, was the son of Rev. John Tenison, rector of Mundsley, Norfolk, by Mary, daughter of Thomas Dowson of Cottenham, Cambridgeshire, where he was born on 29th September, 1636. He was educated at the free school, Norwich, whence he entered Corpus Christi College, Cambridge, as a scholar on Archbishop Parker's foundation. He graduated B.A. in 1657, M.A. in 1660, was chosen fellow in 1662, and became B.D. in 1667. For a short time he studied medicine, but in 1659 was privately ordained. In 1667 he was presented to the living of Holywell-cum-Needingworth, Huntingdonshire, by the earl of Manchester, to whose son he had been tutor, and in 1670 to that of St. Peter's Mancroft, Norwich. In 1680 he received the degree of D.D., and was presented by Charles II. to the important cure of St. Martin's-in-the-Fields. Tenison, according to Burnet, "endowed schools, set up a public library, and kept many curates to assist him in his indefatigable labors." Being a strenuous opponent of the Church of Rome, and "Whitehall lying within that parish, he stood as in the front of the battle all King James's reign." In 1678, in a *Discourse of Idolatry*, he had endeavored to fasten the practices of heathenish idolatry on the Church of Rome, and in a sermon which he published in 1681 on *Discretion in Giving Alms* was attacked by Andrew Pulton, head of the Jesuits in the Savoy. Tenison's reputation as an enemy of Catholicism led the duke of Monmouth to send for him before his execution in 1685, when Bishops Ken and Turner refused to administer the Eucharist; but, although Tenison spoke to him in "a softer and less peremptory manner" than the two bishops, he was, like them, not satisfied with the sufficiency of Monmouth's penitence. Under William, Tenison was in 1689 named a member of the ecclesiastical commission appointed to prepare matters towards a reconciliation of the Dissenters, the revision of the liturgy being specially entrusted to him. A sermon which he preached on the commission was published the same year. He appears to have been better satisfied with the religious sentiments of Nell Gwynn on the approach of death than with those of the duke of Monmouth, for in 1691 he preached her funeral sermon, in which he represented her as truly penitent,—a charitable judgment which did not meet with universal approval. The general liberality of Tenison's religious views commended him to the favor of William, and after being made bishop of Lincoln in 1691, he was promoted to the primacy in December, 1694. He attended Mary during her last illness and preached her funeral sermon in Westminster Abbey. When William in 1695 went to take command of the army in the Netherlands, Tenison was appointed one of the seven lords justices to whom his authority was delegated. Along with Burnet he attended William on his deathbed, and it was from their hands that he received the Eucharist. He crowned Queen Anne, but during her reign was not in much favor at court. He was a commissioner for the Union in 1706. A strong supporter of the Hanoverian succession, he was one of the three officers of state to whom on the death of Anne was entrusted the duty of appointing a regent till the arrival of George I., whom he crowned on 31st October, 1714. Tenison died at London on 14th December of the following year. Besides the sermons and tracts above mentioned, and various others on different points of the Popish controversy, Tenison was the author of *The Creed of Mr. Hobbes examined* (1670) and *Baconia, or Certain Genuine Remains of Lord Bacon* (1679).

The *Memoirs of the Life and Times of the Most Rev. Father in God, Dr. Thomas Tenison, late Archbishop of Canterbury*, appeared without date not long after his death. See also Burnet's *History of his own Time* and Macaulay's *History of England*.

TENNANT, William (1784–1848), author of *Anster Fair*, was born in 1784 at Anstruther in Fifeshire, the birthplace of two other contemporary Scottish worthies, Thomas Chalmers and John Goodsir. He was lame from childhood, like his more famous contemporaries Byron and Scott, and this probably determined his father, who was a small merchant and farmer, to educate him for a scholarly career. But the paternal means failed before he had completed his curriculum at St. Andrews, and he was obliged to return home and act for some eight years of his early manhood as clerk to one of his brothers, a corn-factor. The corn-factor's clerk, however, under the impulse of a genius for language and a strong delight in literature, besides Greek and Latin and Hebrew, mastered, during his leisure, Italian and German, and not only read, but set himself to imitate, Ariosto and Wieland. And, strange to say, this poor youth, in a remote country town, anticipated the fashion of mock-heroic verse, which was set for England by "the ingenious brothers Whistlecraft," and which gave Byron the hint for his *Don Juan*. *Anster Fair*, a fantastic poem in *ottava rima*, amazingly fluent, brimming over with high spirits, rich almost to excess in diction and fanciful imagery, was written by Tennant in 1811, when his brother's business had failed and he did not know where to look for employment. Its publication in 1812 brought the poet into notice, and employment was found for him as schoolmaster of the parish of Dunino, near St. Andrews. From this he was promoted (1816) to the school of Lasswade, near Edinburgh; from that (1819) to a mastership in Dollar academy; from that (1831), by Lord Jeffrey, who had written an admiring review of *Anster Fair*, to the professorship of Oriental languages in St. Andrews. Tennant never fulfilled the promise of his first poem, which reads as if it had been dashed off in a fit of careless and happy inspiration, and never flags in its humorous glee from the first stanza to the last. *The Thane of Fife* (1822), in which he essayed the same vein, evidently cost him more pains, shows the same high reach of humorous imagination, and is indeed, as he claimed for it, "bold in its style and rare, fantastic, and sublime." But the subject was more remote from general interest; the mock-epic machinery, with all his wealth of grotesque description, was too far-fetched for the popular taste; and the poem fell flat. A third poem, in the Scotch dialect, *Papistry Stormed* (1827), though full of the most spirited description, was also in a vein of humor that found few sympathizers. He wrote also two historical dramas, *Cardinal Beaton* (1823) and *John Baliol* (1825). His last published work was a series of *Hebrew Dramas* (1845), founded on incidents in Bible history. He died near Dollar, on 15th February, 1848.

A Memoir of Tennant by M. F. Conolly was published in 1861.

TENNENT, SIR JAMES EMERSON (1794–1869), English politician and traveller, the third son of William Emerson, a merchant of Belfast, was born there on 7th April, 1794. He was educated at Trinity College, Dublin, of which he became LL.D. After travelling in Greece, where he made the acquaintance of Lord Byron, whose sentiments in regard to the Greek cause he fully shared, he studied for the bar and was called at Lincoln's Inn in 1831. He published a *Picture of Greece* (1826), *Letters from the Ægean* (1829), and a *History of Modern Greece* (1830). On his marriage to the daughter and heiress of William Tennent, a wealthy merchant at Belfast, he adopted by royal license the name of his wife in addition to his own. He entered parliament in 1832 as member for Belfast. In 1841 he became secretary to the India Board, and in 1845 he was knighted and appointed colonial secretary of Ceylon, where he remained till 1850. The rusult of his residence there appeared in *Christianity in Ceylon* (1850) and *Ceylon, Physical, Historical, and Topographical* (2 vols., 1859). On his return he became member for Lisburn, and under Lord Derby was secretary to the Poor Law Board from February to November, 1852. From then till 1867 he was permanent secretary to the Board of Trade, and on his retirement he received a baronetcy from Lord Palmerston. In his early years his political views had a Radical tinge, and, although he subsequently joined the Tories, his Conservatism was of a mild type. He withdrew from the Whigs along with Lord Stanley and Sir James Graham, and afterwards adhered to Peel. He died in London on 6th August, 1869.

Besides the books above mentioned, he wrote *Belgium in 1840* (1841) and *Wine, its Duties and Taxation* (1855), and was a contributor to magazines and a frequent correspondent of *Notes and Queries*.

Plate II.

TENNESSEE, one of the United States of North America, the third added (June, 1796) to the original thirteen, its predecessors having been Vermont (1791) and Kentucky (1792). Tennessee is bounded on the E. by the Unaka Mountains, which divide it from North Carolina, on the S. by the line of lat. 35° N., dividing it from Georgia, Alabama, and Mississippi; on the W. by the Mississippi river, dividing it from Arkansas and Missouri; and on the N. by a line which erroneous surveys have caused to vary greatly from the intended boundary,—the line of lat. 36° 30′ N.—the variations all being measured to the north of that parallel. The actual boundary commences at the northeast corner of the State 7 miles north of 36° 30′, and continues at that distance as far as the frontier of Virginia and Kentucky, where it diminishes to 5 miles; thence to about its intersection with 86° 30′ W. it increases to 11 miles; thence a deflection southwards to a point about 2 miles from the Cumberland reduces it to 10 miles; there it suddenly shoots north again to 12 miles, which distance is increased to 12½ by the time it strikes the Tennessee; on the other side of that river it becomes very nearly coincident with the normal 36° 30′; and to that line it adheres with very slight aberrations until it strikes the Mississippi. The eastern boundary has one deviation from the stipulated line: it runs along the culminating ridge of the Unakas till within 26 miles of the Georgia frontier, when it turns due south, giving to Tennessee a triangular piece of territory which should belong to North Carolina. The area of the State was 41,750 square miles in 1880. Its extreme length is 432 miles and its width 109.

Boundaries.

Geology.

Configuration and Geology.—Commencing at the eastern frontier, the State of Tennessee is divided into several districts, having distinct characteristics and separated by well-marked natural boundaries, whose general direction from northeast to southwest corresponds with the trend of the main valleys (see the geological sketch map inserted on pl. II.).

1. The mountain region of East Tennessee is a long narrow belt of very irregular surface, comprised between the Unaka range and a disjointed chain of lower mountains, the principal of which are called the Chilhowee Range, and the whole of which may be considered as constituting the secondary mountain system of the State. The intervening space is occupied by broken masses forming hills, mountains, and valleys, some parallel to the principal ranges, some crossing the space at right angles to them. This region varies in width from 28 miles to about 7. All the rocks of this region and the next to it belong to what constitute in England the Silurian and Cambrian systems, the former being found in the western and the latter in the eastern part of the district. It has been contended that some metamorphic rocks near the crest of the mountains belong to the Archaic (Huronian and Laurentian) system; but the preponderance of geological opinion now assigns them to the same formations as the neighboring rocks, the difference in structure being due to metamorphic action. The lowest of these, called in Tennessee the Ocoee group, is believed to be coeval with the Potsdam group of the American system,—the Lower Silurian and perhaps the upper Cambrian of the British Isles. It consists chiefly of slates and conglomerates, with the sandstones of the Chilhowee group above. Above these last are the Knox dolomite group, with its shales and limestone more separated from the other two groups and perhaps not

exactly corresponding to any other recognized formations. The crystalline metamorphic rocks are mainly syenitic and micaceous gneiss, with micaceous, hornblendic, and talcose schists. Occasional small dykes of diorite, greenstone, and basalt traverse these rocks, sometimes interstratified, but oftener breaking through them.

2. The rocks of the first division are tilted at very high angles; those of the second division, the eastern valley of the Tennessee, are fractured and distorted at nearly every conceivable angle, and, in consequence, it is the edges of the uplifted strata which here form the surface. The strata have been eaten away to form valleys, or left standing as ridges, giving the whole tract a deeply channelled character, the ridges consisting of sandstone and dolomite and the valleys of friable schists. These all trend in the prevalent direction of the Appalachian upheaval, from northeast to southwest. The rivers take the same directions, except when they break through transverse fissures in the ridges, or work round their terminations where they give way to the outcropping of other rocks; in these cases the current runs at right angles to their prevalent direction. All these formations belong to the Silurian period, the oldest cropping out to the eastward, the later members appearing to the westward. In some spots the Subcarboniferous rocks which once covered the entire valley have escaped the erosive action which swept the rest away. The whole district is a valley of denudation which has been excavated by the Tennessee and its tributaries,—some breaking through the Unaka barrier, and others descending from Virginia along the longitudinal valleys above described.

3. Rising in a steep elevation at from 800 to 1200 feet above the average level of the eastern valley of the Tennessee is the plateau popularly called the Cumberland Mountain. This mass, superincumbent on the Silurian system, consists of four very distinctly marked formations,—(i.) the Devonian black shale, (ii.) the Subcarboniferous silicious beds, (iii.) the Mountain Limestone, (iv.) the Coal-measures. These can easily be distinguished one above another on the face of the eastern escarpment; but on the western side the first two extend in a wide plain far beyond the base of the plateau, constituting the fourth district. The Mountain Limestone is shaly at the bottom, and more solid at the top, where it abounds in silicious concretions. The Coal-measures consist of thick slabs of sandstone and conglomerate with the seams of coal interstratified between them. In its southern portion the plateau is divided longitudinally by the narrow valley of the Sequatchie river, which cuts deep into the subjacent Silurian beds. The portion east of this valley, known as Walden's Ridge, has its strata much disturbed and tilted, conformably with the Silurian rocks below; the western portion, on the contrary, has all its strata nearly horizontal. This formation, averaging about 40 miles in width, is divided by a stratum of conglomerate 80 feet thick into the upper and lower Coal-measures, the former of which are much the more productive, but cover a less area, large portions of it having been carried away by denudation. These coal-seams are believed to average an aggregate thickness of 8 feet and to cover an area of 5000 square miles.

4, 5, 6. The Subcarboniferous area, the central basin, and the western valley of the Tennessee can best be considered together. They consist of the Subcarboniferous silicious beds, together with the basins formed by their erosion. On the western face of the Carboniferous belt the Mountain Limestone has been carried away with the harder rocks of the Coal-measures above it, but the underlying silicious beds have resisted all erosive forces and are spread out over an extended area on both sides of the Mississippi. In Tennessee they form a margin round the central basin and are styled by local geologists the "highland rim." They consist of two strata, a lower one distinguished by the absence of lime and iron, and an upper one which contains both these materials in abundance. Both members consist mainly of a peculiar gravel, formed of silicious concretions embedded in a stiff retentive clay. The upper stratum has in addition considerable horizontal beds of limestone; it contains abundant fossils of a large coral, *Lithostrotion canadense*, by which it is easily recognized, is very fertile, and possesses inexhaustible beds of limonite. The lower stratum is destitute of both fossils and minerals and is of but little account for agriculture. Excavated from this formation is the central valley of Tennessee (No. 5), surrounded on all sides by an escarpment of about 200 feet in depth, by which descent is made from the "rim" into the valley. All the members of the Silurian period, except the three lowest, are represented in this valley, which has been formed by the erosive action of the rivers within its borders: its higher strata were carried off northwards by the Cumberland and its tributaries, westward by the Duck, and southward by the Elk, the last two being tributaries of the Tennessee. A channel of erosion along the lower portion of the Duck river connects this valley with another (No. 6) much narrower—the western valley of the Tennessee—where again the Silurian beds have been reached by the removal of the Subcarboniferous formations above them. Again, south of the main basin, the portion drained by the Elk is nearly separated from the rest by a number of detached hills of the Subcarboniferous formation, marking the watershed which divides the headwaters of the Elk from those of the Duck.

7, 8, 9, 10. A little west of the Tennessee river the Palæozoic rocks disappear under the Cretaceous formations (No. 7), and these in their turn are covered successively by the Tertiary, Quaternary, and recent formations (Nos. 8, 9, and 10). The tract of ground covered by these four formations constitutes the Mississippi slope of western Tennessee, all of whose rivers run westward and discharge into the Mississippi. The dip of the strata is very slight, and the surface inclines with a very gentle slope.

In general terms, the territory embraced in Tennessee may be described as a great mountain chain on the east, from the foot of which extends a gently inclined plane, interrupted by an elevation, the Cumberland or Carboniferous plateau, and a depression, the central valley.

Rivers.

Rivers.—The Cumberland and the Tennessee are the principal channels of inland navigation, while the Mississippi, washing the whole western frontier of the State, is its outlet to the Gulf of Mexico. The headwaters and embouchure of the Cumberland are in Kentucky, but much the greater part of its navigable stream is in Tennessee. From its confluence with the Ohio, at Smithland, Kentucky, to Nashville, a distance of 200 miles, it is generally navigable for eight months in the year, and during high water it is sometimes accessible to light-draft steamboats more than 300 miles further. The Tennessee rises in Virginia, crosses east Tennessee in a southwestern direction, and enters Alabama a little above Bridgeport; in that State it assumes successively a westerly and a northerly direction, and then re-enters Tennessee and crosses the State northwards to its confluence with the Ohio at Paducah, Kentucky. Its navigable waters are divided by obstructions into three portions,—(1) from the mouth to Florence, Alabama, 300 miles, where navigation is arrested by the Muscle shoals; (2) thence through Alabama, about 100 miles, when the river breaks through the Cumberland Mountain; and (3) from Chattanooga to Kingston, about 100 miles further.

Agriculture

Agriculture.—In 1880 the number of farms was 165,650, embracing 8,496,556 acres of improved land, valued at $206,749,837. The principal productions are Indian corn, wheat, oats, cotton, tobacco, potatoes, pea-nuts, and hay, particulars of which for different years are shown in Table I. on the following page.

In 1884 1,250,000 bushels of pea-nuts were produced, as against 800,000 in 1883. In recent years considerable attention has been given to the cultivation of fruit and vegetables.

Table I.

Product.	1860.	1870.	1880.	1884.

Minerals.

Minerals.—The chief minerals found in the State are coal, iron, copper, zinc, lead, and manganese. Of coal the output was 494,491 tons in 1880 and 1,100,000 tons in 1885; in the latter year there were also 268,400 tons of coke. In 1880 there were produced 89,933 tons of iron ore (326,040 tons in 1885), 153,880 ℔ of copper ingots, and 792,621 cubic feet of marble and limestone. Of zinc 17,415 tons were produced in 1884. Besides the minerals already mentioned, Tennessee yields millstone grit, hydraulic rock, barytes, fire-clay, gold, and petroleum.

Manufactures.

Manufactures.—Since 1875 the manufacturing industries of the State have grown immensely. From 1880 to 1885 the number of establishments increased from 4326 to 4425, the capital invested from $20,092,845 to $40,763,650, and the value of the manufactured products from $37,074,886 to $75,216,211. In 1880 cotton was manufactured in the State to the value of $934,014 (in 1885 to $2,719,768), carriages and wagons $1,253,721, flour and grist-mill products $10,784,804, foundry and machine-shop products $1,191,531, iron and steel $2,274,203, leather $2,051,087, lumber $4,015,310, and cotton-seed oil, cotton seed, and cake to the value of $1,235,000.

Population.

Population.—The population of the State, which in 1860 was 1,109,801 and in 1870 1,258,520, was in 1880 1,542,359 (males 769,277, females 773,082). Of this last total 403,151 were Negroes. In 1887 the total population was estimated to number about 1,800,000, giving a density of 43 inhabitants to the square mile, as against 36.9 in 1880. The growth of the principal cities is shown by Table III.:

Table III.

	1870.	1880.		1870.	1880.
Memphis..........	40,226	33,592	Knoxville.........	8,682	9,693
Nashville.........	25,865	43,350	Jackson............	4,119	5,377
Chattanooga.....	6,093	12,892			

The considerable decline in the population of Memphis is accounted for by two epidemics of yellow fever in 1878 and 1879 (see Memphis). Chattanooga is still increasing at a very rapid rate in consequence of the vast development of the mineral resources of east Tennessee. Knoxville is also growing from the same cause, but not so rapidly as Chattanooga.

Education.

Education.—Provision for common school education was made before the Civil War, but was limited to white children. A State bank was established for the purpose of regulating the currency, and a portion of its capital was reserved as a school fund; its profits were also to be used for school purposes. The fund on which interest is now paid is $2,512,500. A bill is now (1887) before the State legislature to increase the permanent State fund to $5,000,000. Besides this, the proceeds of a tax of 15 cents per $100 on property and a poll tax of $1 per annum are applied to the same purpose. Moreover, each county has the power of imposing a school tax on its people, and many incorporate cities and towns add still further to it by special taxes within their limits. All children between six and twenty-one (eighteen until 1885) are entitled to free education in the public schools. In 1875 the school population numbered 426,612, of whom there were 199,058 pupils enrolled. In 1886 the corresponding figures were 609,028 and 373,877, and in 1887 623,450 and 383,537. Besides the common schools numerous private schools exist. Higher education is provided for in several institutions, such as Vanderbilt university (Methodist) at Nashville, the university of the South (Episcopalian) at Sewanee or Cumberland Mountain, the southwestern Presbyterian university at Clarksville, and others; the university of Tennessee at Knoxville is supported by State grants, and is not under the direction of any one denomination. Many smaller establishments entitled universities exist in various parts of the State.

Administration.

Administration, etc.—The legislative and executive functions of government are carried on by a governor, a State senate, and a house of representatives, whose respective duties and prerogatives correspond almost exactly to those of the president, senate, and representatives of the United States. Both the senators (33) and the representatives (99) are elected for two years. The president of the senate, who is elected by the senators, succeeds as governor in case of the death of the elected governor during his term of office. The governor has the power of veto on the Acts of the legislature. In case of its exercise, the Act is returned to the legislature, when, if it passes by a constitutional majority in both houses, it becomes law in spite of the veto.

The judiciary administration is carried on by courts of four designations,—the county criminal courts, the circuit courts, the chancery courts, and the supreme court of the State. The county courts consist of the magistrates, who assemble at the county seat four times a year to transact county business. They elect a chairman out of their own body, who by virtue of such election becomes the financial agent of the county. In counties large enough to justify it, a county judge is elected, who exercises criminal jurisdiction. There are fourteen circuit courts, each having jurisdiction in several counties; in these all common-law cases are adjudicated, except in those counties where there is a criminal judge. There are eleven chancery divisions, for each of which a chancellor is elected, who tries all cases in equity in his division. All these judges are elected for eight years. The judges of the supreme court, five in number, are elected by the people at large, but not more than two can be taken from any one of three divisions of the State, viz., the eastern, middle, and western. Their jurisdiction is purely appellate; they revise the decisions of the other courts, and their decisions are final, except where a question arises as to the interpretation of the United States constitution.

History.

History.—At the time of its first settlement and occupation by Europeans Tennessee was part of the territory granted to the colony of North Carolina by Charles II. It was then, however, a hypothetical claim, the boundaries of which were chiefly determined by 36° 30′ and 35° N. lat. The eastern boundary of North Carolina was the Atlantic Ocean; on the other side the western territory extended according to one theory to the Mississippi, according to another theory to the Pacific Ocean. When the English settlers began to cross the Appalachian chain, they found the French established on the Mississippi and its tributaries,—the Ohio, the Tennessee, and the Cumberland. The Spanish claim of an indefinite extension of their possessions in Florida was also a constant menace to the advances of the earliest English colonists in the direction of South Carolina and Georgia. The most important effort of transmontane colonization by the British prior to 1760 was the establishment of Fort Loudon on the Little Tennessee river in 1756 or 1757. But in 1760 this post was captured by the Cherokees and its garrison massacred; and the same fate befell a number of colonists who had settled between Fort Chissel (on New river, Virginia) and Fort Loudon. Early in 1761 Colonel Grant completely routed the Cherokees and compelled their French and Spanish allies to withdraw to Louisiana and Georgia.

Eight years later the stream of emigration began to set westwards, mainly by two routes, of which one led through Cumberland Gap to the valley of the Cumberland river, whilst the other followed the course of the Tennessee round the southern border of the Cumberland plateau into the western Tennessee valley. A body of emigrants from Virginia settled on the banks of the river Holston, in what is now Hawkins county, and formed the nucleus of a rapidly increasing colony, which was mainly recruited from Virginia and North Carolina. The chief settlements were on the Watauga river, extending thence to the Nolichucky, both tributaries of the Tennessee. The colonists adopted a code of laws for themselves based upon those of Virginia, and entrusted their execution to a bench of five magistrates. Their first trouble related to the title to their lands. They supposed themselves to be settling in Virginia; but they were really in North Carolina, and therefore outside of the territory which had been ceded to the British crown by the six nations of Indians. A further obstacle was a royal proclamation dated nine years before forbidding private persons to purchase titles from the Indians. Though the Cherokees had no longer fixed habitation in the country, they still claimed the whole valley for hunting grounds. The dilemma was solved by a lease negotiated for eight years. The next difficulty arose with the British Government in alliance with the hostile Indians. But out of these troubles the colonies on the Watauga, Holston, and Nolichucky emerged as a populous and powerful community.

When it was proposed to liquidate the debts incurred by both the States and the Federal Government for war expenses by the sale of public lands, an Act of Cession was passed in 1784 by the North Carolina legislature ceding their lands west of the mountains, including those of the Watauga settlers, to the Federal Government. But in the following year the North Carolina legislature repealed the Act of Cession, and the whole matter was thus indefinitely postponed. The Watauga community now declared itself independent of North Carolina; that State had relinquished its sovereignty over them and the Federal Government had not accepted it. At this time the transmontane territory consisted of Washington, Sullivan, and Greene counties. It also embraced all the settlements on the Cumberland, comprising the existing counties of Davidson, Sumner, Montgomery, Robertson, and Williamson. Davidson county had been organized by the influence of James Robertson (one of the earliest arrivals from North Carolina, in 1769), who had moved to the site of the future city of Nashville. But Davidson county took no part in these proceedings. The State organized by the seceding counties in August, 1784, was called the State of Franklin; its constituent counties returned to their allegiance to North Carolina on 1st March, 1788. A second Act of Cession was passed in 1790, by which the defunct State of Franklin became part of the territory of the United States south of the Ohio, including what now constitutes Kentucky and Tennessee. The northern portion became a State, under the name of Kentucky, in 1792, and the southern portion took rank as the State of Tennessee in 1796, being received into the Union the same year. The settlement of middle Tennessee was much retarded so long as the path of access to it from east Tennessee was through Cumberland Gap and down the Ohio. The broader route round the south of the Cumberland plateau by the Tennessee river was too unsafe for general use on account of the powerful Indian tribes—the Creeks and the Cherokees. This obstacle was finally removed by General Jackson's crushing defeat of the Creeks in 1814, and a large cession of their territory.

The position of Tennessee during the Civil War was the same as that of the other Middle and Southern States. While secession was in agitation, it refused to secede; but when actual hostilities commenced it joined the Southern Confederacy. Even then, however, west and middle Tennessee sympathized with the South, whilst eastern Tennessee sided with the North. Each division sent very large contingents to the army which it favored. A large portion of the State was, during the later years of the war, in the occupation of the Northern army, and many great battles were fought on its soil, notably those of Fort Donelson, Murfreesborough (Stone River), Franklin and Nashville. Tennessee suffered more from the exhaustion attendant on the close of the war, and from the rigorous government which accompanied the period of reconstruction, than any other State except Virginia.

Jour. of Sc.*, April, 1883; Bradley, "On the Silurian Age of the Southern Appalachians," *ib.*, April, 1875; Haywood, *The Civil and Political History of the State of Tennessee from its Earliest Settlement up to the Year* 1796, Knoxville, 1823; Ramsay, *Annals of Tennessee to the End of the Eighteenth Century*; Parton, *Life of Andrew Jackson*, New York, 1860; Kirke, *The Rear Guard of the Revolution*, New York, 1886; *Reports* of Tennessee Hist. Soc. and of Bureau of Agriculture, Mines and Immigration. (D. F. W.)

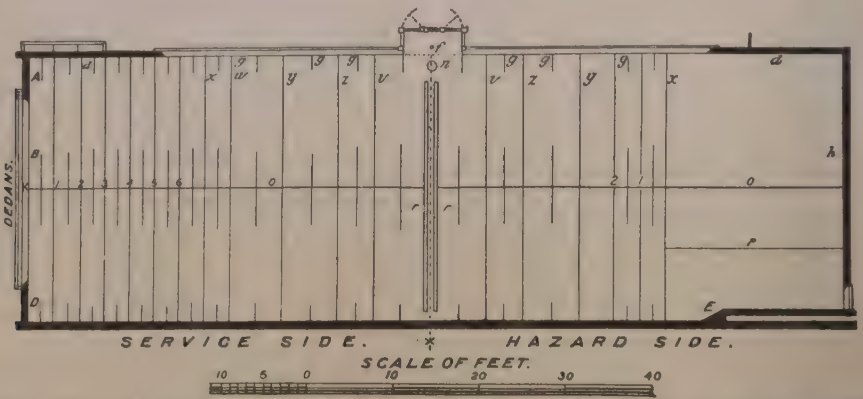
TENNIS. This, the oldest, perhaps, of all existing ball-games, is at once the most difficult to learn, on account of the intricacy of its laws, and the most interesting when learnt, because of the great variety of its combinations and the difficulty of solving rapidly the problems which are constantly presented to the player. It derives an additional claim to attention from numberless historical associations. Of the origin of tennis it is not possible to speak with certainty; but it may be confidently assumed that it sprang from some very simple sport. It first appeared in Europe in the Middle Ages, when we find it played in open courts, in the parks or ditches of the feudal castles of France and Italy. It was at first the pastime of kings and nobles, but afterwards became popular with all classes. The French seem to have borrowed it from the Italians, and to have contributed some of its refinements; and the English took it from the French. Though mentioned in the Arthurian romances, the game was certainly not known in England in the time of Arthur. The name *tennis* is supposed to be derived from the exclamation "Tenez!" employed by early French players in serving the ball. In Italy the game is called "giuoco della palla;" in France, "jeu de paume," which also means the tennis court; in Germany it is called by the generic title of "Ballspiel;" in Spain, "juego al ble" or "jugar al ble." It is clear from the French name that the ball was originally struck with the palm of the hand. This was afterwards protected by a glove, as is still the practice in the Basque country. Upon the glove strings and cross-strings were next stretched, to give a faster impulse; and the addition of a short handle made an easy transition to the racket. In the time of Henry VII. the hand still sometimes met the racket, even in the royal court at Windsor.

One of the first improvements in the game consisted in the building of closed courts, first with walls, then with walls and roof. It is still played in the open air in some places in France, and "pallone," a rude and violent variety of the game, is yet seen in Italy. There are twenty-seven courts in England and one in Dublin.

As now played, tennis in France is virtually the same as in England, though there are a few differences of detail. The court is rectangular (see the annexed plan). An inner wall runs round three sides, to the height of 7 feet, from which a sloping roof, called the penthouse, reaches to the outer wall. The surrounding passage thus enclosed (not shown in plan) is 7 feet wide. Opposite to the long penthouse is the main wall, in which there is at one point a projection called the *tambour*, *E*, which deflects the ball across the court. In the inner wall, below the penthouse, there are several openings, the one at the end, on the service side, being called the *dedans*, *B*, the others the *galleries*. At the further end of the court is the *grille*, a square opening adjacent to the main wall. Across the court, halfway between the two ends, is stretched a net *n*, 3 feet high in the middle and 5 feet at the sides. The game may be played by two, or by three, or by four players, one against one, one against two, or two against two. At the commencement the players toss or "spin" a racket to decide which shall serve first, calling "rough" (for the knotted side) or "smooth." The party which wins the "spin" has the choice of the service or the "first stroke," the latter term meaning the return of the service. The server then begins at the "dedans" end of the court, technically called the "service side," pitches the ball in the air, and strikes it with his racket so that it shall drop on the side penthouse or on the wall above it, and then from the penthouse upon the floor on the other side of the net (called the "hazard side"), within the "service court" bounded by the "service line" *x* and the "pass line" *p*. If he fail to do this, a "fault" is called, or a "pass" if the ball has gone beyond the pass line. If he serves a second fault, his adversary scores a point, called a "stroke." A pass counts for nothing, but annuls a previous fault.[1] It now becomes the duty of the adversary, called the "striker-out," to return the ball by striking it with his racket in such a manner that it shall pass back over the net to the service side. The server must now strike it again and return it to the hazard side; and the player who first returns the ball into the net or "out of court" (*i.e.*, to the roof, or above the play line on the walls) loses the stroke, which is scored to his antagonist. But, if a player fail or refuse to strike the ball in the air (a "volley") or on its first bound and before it touches the floor a second time, then, except on the hazard side beyond the service line, a "chase" is made or reckoned on the floor, according to the lines on or between which the ball has dropped the second time. This chase is a stroke in abeyance. When one has been made it is called by the marker, but does not affect the score until one of the players has scored 40, when they change sides, and the player who has allowed the chase to be made must then endeavor to win it, *i.e.*, to place the second bound of the ball returned by him better, *i.e.*, nearer to the end wall, than the point at which the chase was marked. As often as his adversary returns his stroke, he must again endeavor to do this, until he succeeds or fails. If he succeed, he scores the stroke; if not, it is scored to his adversary. If two chases have been made at any stage of the score, even at the beginning of a game, then the players must change sides and play for the chases, as above described. A player who succeeds in sending the ball into the grille, the dedans, or the last division of the gallery—called the "winning gallery"—on the hazard side, scores at all times a stroke. The minutiæ of the game and the mode of scoring cannot be more succinctly described than in the annexed laws.[1]

---

[1] In the Manchester Club this law (8) has been wisely abolished.



Plan of tennis court. *A*, *D*, walls on each side of dedans; *d*, *d*, gallery walls; *h*, grille wall; *f*, net post; *g*, *g*, gallery post; *v*, *v*, first galleries; *y*, *y*, second galleries; *x*, *x*, last galleries; *z*, *z*, doors; *o*, *o*, half-court line; *r*, *r*, openings under net for ventilation and warming; 1, 2, 3, 4, 5, 6, mark chases.

LAWS.

Single-Handed Game.

1. The balls shall be not less than 2¼ in. and not more than 2⅝ in. in diameter, and shall be not less than 2½ oz. and not more than 2¾ oz. in weight.

Note.—There is no restriction as to the shape or size of the rackets.

2. (*a*) The choice of sides at the beginning of the first set is determined by a spin.
   (*b*) In subsequent sets of a series, the players shall begin each set on the side on which they finished the set before it.

3. The ball served must be struck with the racket, and may be delivered from any part of the service side.

4. The ball served must touch the service penthouse before touching any other part of the court, except the rest of the side penthouse and the service wall; and it must drop in the service court or on one of the lines which bound it.

5. The service is good,
   (*a*) if the ball served touch in its descent any part of the service penthouse so as to rise again from it, or
   (*b*) if the ball served strike the service wall and afterwards touch in its descent any part of the service penthouse, even though it do not rise again from it, or
   (*c*) if the ball served drop in the winning gallery.

6. A fault may not be returned.

7. A pass may not be returned; but a ball served, which has not gone across the pass line on the penthouse, may be volleyed, although if untouched it might have dropped in the pass court. If a pass touch the striker-out, or if a service before it has dropped, touch him when standing with both feet in the pass court, and not having attempted to strike the ball, it is still counted a pass.

8. A pass annuls a previous fault.

9. If the striker-out declare himself not ready for a service, and have made no attempt to return it, that service is counted for nothing, though it be a fault. It annuls a previous fault. The striker-out, having been asked if he is ready, and having declared himself ready, may not similarly refuse a second service.

10. The server continues to serve until two chases be made, or one chase when the score of either player is at forty or advantage (see law 25). The players then change sides, the server becoming striker-out and the striker-out becoming server.

11. The return is good if the ball in play be struck with the racket so that it pass the net without touching a gallery post or anything fixed or lying in an opening on the side from which it is struck, and without going out of court.

12. The return is not good,
   (*a*) if not in accordance with the terms of law 11, or
   (*b*) if the ball be struck more than once, or be not definitely struck, or
   (*c*) if the ball in play, having passed the net, come back and drop on the side from which it was struck, unless it should have touched a gallery post or anything fixed or lying in an opening on that side of the court which is opposite to the striker.

13. A ball which is no longer in play may not be returned.

14. The server wins a stroke (except as provided in law 9),
   (*a*) if a good service enter the winning gallery or the grille, or
   (*b*) if the striker-out fail to return a good service (except when it makes a chase; see laws 17–19), or
   (*c*) if the striker-out fail to return the ball in play (except when it makes a chase; see laws 17–19), or
   (*d*) if he himself return the ball in play so that it enter the winning gallery or grille, or fall on or beyond the service line, or
   (*e*) if he serve or return the ball in play so that it drop or fall upon a ball or other object which is on or beyond the service line, or
   (*f*) if he win a chase (see law 20), or
   (*g*) if the striker-out lose a stroke (see law 16).

15. The striker-out wins a stroke (except as provided in law 9),
   (*a*) if the server serve two consecutive faults (except as provided in law 31 (*b*), or
   (*b*) if the server fail to return the ball in play (except when it makes a chase; see laws 17–19) or
   (*c*) if he himself return the ball in play so that it enter the dedans, or
   (*d*) if he win a chase, or
   (*e*) if the server lose a stroke (see law 16).

16. Either player loses a stroke,

---

[1] Reprinted from the present writer's *Annals of Tennis*, 1878, by the kind consent of the publisher, Mr. H. Cox.

(*a*) if he lose a chase (see law 21),
(*b*) if the ball in play (except as provided in law 7) touch him or anything which he wears or carries, except his racket in the act of returning the ball, or
(*c*) if he touch or strike the ball in play with his racket more than once, or do not definitely strike it.

17. When a ball in play on either side of the net, not being that on which the striker is standing,
(*a*) falls on any part of the floor, except on or beyond the service line, or
(*b*) enters any gallery, except the winning gallery, or
(*c*) touches a gallery post,
it is marked a chase
(*α*) at that line on the floor on which it fell, or
(*β*) better or worse than that line on the floor which is nearest to the point at which it fell, or
(*γ*) at that gallery the post of which it touched,
except as provided in laws 18 and 19.

Note (*a*).—A ball in play which touches the net post and drops on the side opposite to the striker is marked a chase at the line on the side on which it drops.

Note (*b*).—A ball in play which enters a gallery is marked a chase at that gallery which it enters, notwithstanding that it may have touched an adjacent gallery post without touching the floor in the interim.

Note (*c*).—The gallery lines on the floor correspond and are equivalent to the galleries of which they bear the names.

18. When a ball in play
(*a*) drops or falls in the net, on the side opposite to the striker, or
(*b*) drops on the floor, on the side opposite to the striker, and, bounding over the net, falls on that side of it from which it was struck, whether it touch the net in its bound or not,
it is marked a chase at the line on the side opposite to the striker.

19. When a ball in play drops or falls upon a ball or other object which is on the floor (except when it is on or beyond the service line; see law 14 (*e*)), it is marked a chase at the point at which that ball or other object was when the ball in play dropped or fell upon it.

20. Either player wins a chase,
(*a*) if he serve or return the ball so that it enter a winning opening, or
(*b*) if he serve or return the ball so that it fall better than the chase for which he played, or enter a gallery or touch a gallery post better than the gallery or the gallery line at which the chase was for which he played, or
(*c*) if he serve or return the ball so that it drop or fall upon a ball or other object which is at a point on the floor better than that at which, or at the gallery corresponding to which, the chase was for which he played, or
(*d*) if his antagonist fail to return the ball in play, except when it falls worse than the chase in question.

21. Either player loses a chase,
(*a*) if he fail to return the ball in play, except when it falls worse than the chase in question, or
(*b*) if he return the ball in play so that it fall worse than the chase, or enter a gallery or touch a gallery post worse than the gallery or the gallery line at which the chase was for which he played, or
(*c*) if he return the ball in play so that it drop or fall upon a ball or other object which is at a point on the floor worse than that at which the chase was for which he played.

22. When a ball in play
(*a*) falls at a point on the floor neither better nor worse than that at which, or at the gallery corresponding to which, the chase was for which the striker played, or
(*b*) enters that gallery or the gallery corresponding to that gallery line, or touches the post of that gallery, or falls on the gallery line corresponding to that gallery, at which the chase was for which the striker played, or
(*c*) drops or falls upon a ball or other object which is at a point on the floor neither better nor worse than that at which, or at the gallery corresponding to which, the chase was for which the striker played,
it is marked chase-off: it is not scored as a stroke won by either player; the chase is annulled, and the striker has not to play for it again.

23. As soon as two chases are marked, or one chase when the score of either player is at forty or advantage (see law 25), the players change sides. The player who made the first chase now defends it, while the other plays to win it; and so with the second chase except when only one has been marked.

24. If by an error three chases have been marked, or two chases when the score of either player is at forty or advantage (see law 25), the last chase in each case is annulled.

25. On either player winning his first stroke, the score is called fifteen for that player; on either player winning his second stroke, the score is called thirty for that player; on either player winning his third stroke, the score is called forty for that player; and the fourth stroke won by either player is scored game for that player, except as below.

If both players have won three strokes, the score is called deuce, and the next stroke won by either player is scored advantage for that player. If the same player win the following stroke, he wins the game; if he lose the following stroke, the score is again called deuce; and so on, until either player win the two strokes immediately following the score of deuce, when the game is scored for that player.

26. The player who first wins six games wins a set, except as below.

If both players win five games, the score is called games all, and the next game won by either player is scored advantage game for that player. If the same player win the following game he wins the set; if he lose the following game, the score is again called games all; and so on, until either player win the two games immediately following the score of games all, when he wins the set.

Note.—Players often agree not to play advantage sets, but to decide the set by one game after arriving at the score of games all.

27. Every chase is marked, and every stroke scored, by the marker, who is entitled to consult the dedans when he is in doubt. A player who is dissatisfied with the marker's decision is entitled to appeal to the dedans. A majority of the dedans confirms or reverses the marker's decision. An appeal must be made before a recommencement of play.

Note.—The dedans should not give a decision unasked on a question of marking a chase or stroke, but may, and should, correct inaccurate scoring of chases, strokes, games, or sets.

Three-Handed and Four-Handed Games, sometimes called Double Games.

28. The partners serve and strike-out in alternate games, unless it shall have been previously agreed to the contrary.

Note.—It is usually, but not always, agreed that the striker-out may leave to his partner such services as pass him.

The former laws apply to these as well as to single games, the advantages and disadvantages attaching to a single player under the former laws here attaching to a pair of players.

Odds.

29. (*a*) A bisque or a half-bisque may not be taken after the service has been delivered.
(*b*) The server may not take a bisque after a fault; but the striker-out may do so.

Note.—A bisque is a stroke which may be claimed by the recipient of odds at any time during a set, subject to the provisions of laws 29 and 30.

30. A player who wishes to take a bisque or a half-bisque, there being a chase or two chases marked, may take it either before or after changing sides; but he may not, after changing sides go back to take it.

31. (*a*) When the odds of round services are given, the ball served by the giver of the odds must touch the grille penthouse after touching the service penthouse and before dropping in the service court or on one of the lines which bound it.
(*b*) Neither faults nor failure in complying with the above condition are counted against the giver of the odds; but the recipient of the odds may decline to return such services as do not touch both the penthouses; if, however, he attempt and fail to return any such service, it is counted against him.

32. Half-court: the players having agreed into which half-court on each side of the net the giver of the odds shall play, the latter loses a stroke if the ball returned by him drop in either of the other half-courts.

But a ball returned by the giver of the odds which
(*a*) drops on the half-court line, or
(*b*) drops in his half-court and touches the dedans post before falling, or

(*c*) drops in his half-court and falls in the dedans, even though on the other side of the dedans post, or
(*d*) touches the dedans post before dropping,
is counted for the giver of the odds.

And a return boasted against any wall by the giver of the odds which
(*e*) drops in his half-court, or
(*f*) drops on the half-court line, or
(*g*) touches the dedans post before dropping, or
(*h*) touches any penthouse, battery, or wall before dropping in his half-court, dropping on the half-court line, or touching the dedans post, is also counted for the giver of the odds.

Note.—It is, of course, evident that the giver of these odds may make a chase, or win a chase or a stroke, with a ball which drops in his half-court, or on the half-court line, but falls in the other half-court.

33. When the odds of "touch no walls" or "touch no side walls" are given, a ball returned by the giver of the odds which on falling makes a nick is counted for the striker.

Directions to the Marker.

It is the duty of the marker
- to call the faults, and the passes;
- to call the strokes, when won, or when he is asked to do so;
- to call the games and sets at the end of each, or when asked to do so;
- to mark the chases, when made;
- to call the chases when there are two in the order in which they were made, or the chase when there is one with the score at forty or advantage; and then
- to direct the players to change sides;
- to call the chase or chases again, in order as above, when the players have changed sides, and each chase as a player has to play for it;
- not to call *play* or *not play* in doubtful cases before the conclusion of the rest, unless asked to do so;
- to decide all doubtful and disputed strokes, subject to an appeal to the dedans;
- to warn the players of any balls lying on the floor in their way, or to their danger or disadvantage, and to remove all such balls;
- to collect the balls into the ball-basket; and
- to keep the ball-troughs constantly replenished in the dedans and last gallery, and the latter especially in three-handed and four-handed games. (J. MA*.)

TENNIS, LAWN. Lawn-tennis is a modern adaptation of the first principle of tennis, in the simplest form, to a ball-game played on grass with rackets. The balls are of india-rubber, hollow, and covered with white cloth. The rackets are lighter and broader than those used at tennis. The court for the single-handed game, one player against one, is shown in Fig. 1, that for the three- or four-handed game in Fig. 2. The dimensions of the courts, the size and weight of the balls, the mode of scoring, and other details are given in the laws of the game (see below). The only requisites for the game are the balls, rackets, net and posts, and a hard level surface of grass. It may be, and often is, played upon surfaces of wood, asphalt, cement, gravel, or other substance. The grass requires constant mowing, rolling, and in dry weather watering, to keep it in order. In the winter months it should be sedulously weeded, sown where necessary, and swept and rolled whenever the weather permits.

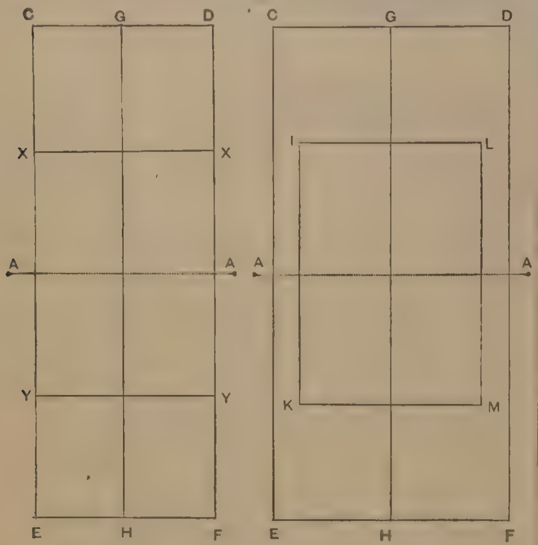


FIG. 1. FIG. 2.

Lawn-tennis courts. Fig 1, for single game; Fig. 2, for double game.

The choice of sides depends upon a toss or spin of a racket, as in tennis. The winner chooses the service or the preferable side, as he pleases. The server begins the game by striking the ball with his racket so that it passes (without touching) over the net, which is hung across the court from the posts A, A. The ball served must drop in the space which is diagonally opposite to him on the other side of the net,—a space bounded by the net, the side line, the half-court line, and the service line. His adversary, called the "striker-out," must return the ball before it touches the ground a second time; and the server must similarly return it again; and so on, until one or the other player fails to return it over the net so that it shall drop on the ground anywhere on the side of the net furthest from him, and within or upon any of the lines which bound that space, technically called his adversary's *court*. When one player thus fails, he loses a stroke, which the other is deemed to win, and it is added to the score of the latter. The score is kept as at tennis, but there are no chases.

Activity and condition have great value in lawn-tennis, though there is room for much skill in placing the ball in the corners with hard, low strokes, and in intercepting and returning the ball by the volley while in the air, before it reaches the ground. But in matches temper, endurance, and quickness of movement count for very much.

Lawn-tennis, in one form or another, has been played for many centuries out-of-doors. The present variety of the game was first introduced, in a form which was soon shown to be impracticable, about the year 1874. It was then taken up by the All England Club at Wimbledon, who in 1877 remodelled the size and shape of the court, and the laws, and altered the system of scoring to that which obtains in the parent game. Thereupon, with the consent of the M. C. C. at Lord's, who lent the authority of their name to the movement, the code of laws which now prevails, and has been occasionally amended only in a few details, was promulgated by the All England Club. The championship of the game, which is open to gentlemen amateurs only, was instituted at Wimbledon by the A. E. C. in 1877. A lady's championship and a championship for pairs (gentlemen) have also been instituted, and are annually competed for on the grounds of the A. E. C. at Wimbledon. Lawn-tennis, in the short time which has elapsed since its introduction, has achieved immense popularity. Prize-meetings are held annually at Bath, Cheltenham, Dublin, Edinburgh, Manchester, Liverpool, and many other places in the United Kingdom; the game is also played with as great enthusiasm in the United States, Canada, Australia, and India. In all those countries prize-meetings are held and championships are instituted.

LAWS.[1]

Single-Handed Game.

1. For the single-handed game the court is 27 feet in width and 78 feet in length. It is divided across the middle by a net, the ends of which are attached to the tops of two posts A and A (see Fig. 1), which stand three feet outside the court on each side. The height of the net is 3 feet 6 inches at the posts and 3 feet at the centre. At each end of the court, parallel to the net and at a distance of 39 feet from it, are drawn the base lines CD and EF, the extremities of which are connected by the side lines CE and DF. Half-way between the side lines, and parallel to them, is drawn the half-court line GH, dividing the space on each side of the net into two equal parts, called the right and left courts. On each side of the net, at a distance of 21 feet from it, and parallel to it, are drawn the service lines XX and YY.

---

[1] Printed by permission of the All England Lawn-Tennis Club.

2. The balls shall be not less than $2\frac{1}{2}$ inches nor more than $2\frac{9}{16}$ inches in diameter, and not less than $1\frac{7}{8}$ oz. nor more than 2 oz. in weight.

3. In matches where umpires are appointed their decision shall be final: but where a referee is appointed an appeal shall lie to him from the decision of an umpire on a question of law.

4. The choice of sides and the right of serving during the first game shall be decided by toss, provided that, if the winner of the toss choose the right to serve, the other player shall have the choice of sides, and *vice versa*.

5. The players shall stand on opposite sides of the net. The player who first delivers the ball shall be called the server, the other the striker-out.

6. At the end of the first game the striker-out shall become server and the server shall become striker-out; and so on alternately in the subsequent games of the set.

7. The server shall stand with one foot beyond (*i.e.*, further from the net than) the base line, and with the other foot upon the base line, and shall deliver the service from the right and left courts alternately, beginning from the right.

8. The ball served must drop within the service line, half-court line, and side line of the court which is diagonally opposite to that from which it was served, or upon any such line.

9. It is a fault if the service be delivered from the wrong court, or if the server do not stand as directed in law 7, or if the ball served drop in the net or beyond the service line, or if it drop out of court or in the wrong court; it is not a fault if the server's foot which is beyond the base line do not touch the ground at the moment at which the service is delivered.

10. A fault may not be taken.

11. After a fault, the server shall serve again from the same court from which he served that fault, unless it was a fault because served from the wrong court.

12. A fault may not be claimed after the next service has been delivered.

13. The service may not be volleyed, *i.e.*, taken before it touches the ground.

14. The server shall not serve until the striker-out is ready. If the latter attempt to return the service he shall be deemed to be ready.

15. A ball is in play from the moment at which it is delivered in service (unless a fault) until it has been volleyed by the striker-out in his first stroke, or has dropped in the net or out of court, or has touched either of the players or anything that he wears or carries, except his racket in the act of striking, or has been struck by either of the players with his racket more than once consecutively, or has been volleyed before it has passed over the net, or has failed to pass over the net before its first bound (except as provided in law 17), or has touched the ground twice consecutively on either side of the net, though the second time may have been out of court.

16. It is a let if the ball served touch the net, provided the service be otherwise good, or if a service or fault be delivered when the striker-out is not ready, or if either player be prevented by an accident beyond his control from serving or returning the ball in play. In case of a let, the service or stroke counts for nothing, and the server shall serve again.

17. It is a good return although the ball touch the net, or, having passed outside either post, drop on or within any of the lines which bound the court into which it is returned.

18. The server wins a stroke if the striker-out volley the service, or fail to return the service or the ball in play (except in the case of a let), or return the service or ball in play so that it drop outside any of the lines which bound his opponent's court, or otherwise lose a stroke, as provided by law 20.

19. The striker-out wins a stroke if the server serve two consecutive faults, or fail to return the ball in play (except in the case of a let), or return the ball in play so that it drop outside any of the lines which bound his opponent's court, or otherwise lose a stroke, as provided by law 20.

20. Either player loses a stroke if the ball in play touch him or anything that he wears or carries, except his racket in the act of striking, or if he touch or strike the ball in play with his racket more than once consecutively, or if he touch the net or any of its supports while the ball is in play, or if he volley the ball before it has passed the net.

21. On either player winning his first stroke, the score is called 15 for that player; on either player winning his second stroke, the score is called 30 for that player; on either player winning his third stroke, the score is called 40 for that player; and the fourth stroke won by either player is scored game for that player, except as below.

If both players have won three strokes, the score is called deuce; and the next stroke won by either player is scored advantage for that player. If the same player win the next stroke, he wins the game; if he lose the next stroke, the score is again called deuce; and so on until either player win the two strokes immediately following the score of deuce, when the game is scored for that player.

22. The player who first wins six games wins a set, except as below.

If both players win five games, the score is called games all; and the next game won by either player is scored advantage game for that player. If the same player win the next game, he wins the set; if he lose the next game, the score is again called games all; and so on until either player win the two games immediately following the score of games all, when he wins the set.

Note.—Players may agree not to play advantage sets, but to decide the set by one game after arriving at the score of games all.

23. The players shall change sides at the end of every set; but the umpire, on appeal from either party before the toss for choice, may direct the players to change sides at the end of every game if in his opinion either side have a distinct advantage, owing to the sun, wind, or any other accidental cause; but, if the appeal be made after a match has been begun, the umpire may only direct the players to change sides at the end of every game of the odd and concluding set.

24. When a series of sets is played, the player who was server in the last game of one set shall be striker-out in the first game of the next.

Odds.

25. A bisque is one stroke, which may be claimed by the receiver of the odds at any time during a set, except as below.

A bisque may not be taken after the service has been delivered.

The server may not take a bisque after a fault; but the striker-out may do so.

26. One or more bisques may be given in augmentation or diminution of other odds.

27. Half-fifteen is one stroke given at the beginning of the second and every subsequent alternate game of a set.

28. Fifteen is one stroke given at the beginning of every game of a set.

29. Half-thirty is one stroke given at the beginning of the first game, two strokes at the beginning of the second game; and so on, alternately, in all the subsequent games of a set.

30. Thirty is two strokes given at the beginning of every game of a set.

31. Half-forty is two strokes given at the beginning of the first game, three strokes at the beginning of the second game; and so on, alternately, in all the subsequent games of a set.

32. Forty is three strokes given at the beginning of every game of a set.

33. Half-court: the players having agreed into which court the giver of the odds shall play, the latter loses a stroke if the ball, returned by him, drop outside any of the lines which bound that court.

Three-Handed and Four-Handed Games.

34. The above laws shall apply to the three-handed and four-handed games, except as below.

35. For the three-handed and four-handed games the court is 36 feet in width. Within the side lines, at a distance of $4\frac{1}{2}$ feet from them, and parallel to them, are drawn the service side lines IK and LM. The service lines are not drawn beyond the points I, L, K, and M, towards the side lines. In other respects, the court is similar to that which is described in law 1.

36. In the three-handed game the single player shall serve in every alternate game.

37. In the four-handed game the pair who have the right to serve in the first game may decide which partner shall do so, and the opposing pair may decide similarly for the second game. The partner of the player who served in the first game shall serve in the third; and the partner of the player who served in the second game shall serve in the fourth; and so on in the same order in all the subsequent games of a set.

38. The players shall take the service alternately throughout each game. No player shall receive or return a service delivered to his partner. The order of service and of striking-out once arranged shall not be altered, nor shall the strikers-out change courts to receive the service, before the end of the set.

39. The ball served must drop within the service line, half-court line, and service side line of the court which is diagonally opposite to that from which it was served, or upon any such line.

40. It is a fault if the ball served do not drop as provided in law 39, or if it touch the server's partner or anything that he wears or carries.

41. If a player serve out of his turn, the umpire, as soon as the mistake is discovered by himself or by one of the players, shall direct the player to serve who ought to have served; but all strokes scored and any fault served before such discovery shall be reckoned. If a game shall have been completed before such discovery, then the service in the next alternate game shall be delivered by the partner of the player who served out of his turn; and so on in regular rotation. (J. MA*.)

TENT. A tent is a portable habitation or place of shelter consisting in its simplest form of a covering of some textile substance stretched over a framework of cords and poles, or of wooden rods, and fastened tightly to the ground by pegs. Throughout the greater part of the interior of Asia the pastoral tribes have of necessity ever been dwellers in tents,—the scantiness of water, the consequent frequent failure of herbage, and the violent extremes of seasons compelling a wandering life. Tents have also been used in all ages by armies in campaign. In ancient Assyrian sculptures discovered by Layard at Nineveh the forms of tent and tent furnishings are similar to those which still prevail in the East, and it appears that then as now it was a custom to pitch tents within the walls of a city. The ordinary family tent of the Arab nomads of modern times is a comparatively spacious ridged structure, averaging from 20 to 25 feet in length, but sometimes reaching as much as 40 feet. Its covering consists of a thick felt of black goat hair (cp. Cant. i. 5), or sometimes of alternate stripes of black and white disposed horizontally. The ridge or roof is supported by nine poles (*awamid*) disposed in sets of three, the central set being loftier than those at each end, whereby a slope outward is formed which helps to carry off rain. The average height inside at the centre is 7 feet and at the sides 5 feet, and the cloths at the side are so attached that they can easily be removed, the sheltered end being always kept open. Internally the tent is separated by a partition into two sections, that reserved for the women containing the cooking utensils and food. The *jourt* or tent of the Kirghiz of Central Asia is a very capacious and substantial structure, consisting of a wooden frame for sides, radiating ribs for roof, and a wooden door. The sides are made up of sections of laths, which expand and contract in lozenges, on the principle of lazy tongs, and to their upper extremities ribs are lashed at regular intervals. Over this framework a heavy covering of felt is thrown, which is either weighted down with stones or, when necessary, stitched together.

In Western countries tents are used chiefly in military encampments, by travellers and explorers, and for temporary ceremonial occasions and public gatherings. The material of which they are composed is commonly a light linen canvas or navy duck; but for tents of small size stout cotton canvas is employed, being light, strong, elastic, and sufficiently waterproof. These tents vary in size from a low-pitched covering, under which a couple of men can with difficulty creep, up to spacious marquees, in which horticultural and agricultural shows are held, and which can accommodate thousands of persons.

The marquee is distinguished from the tent by being a ridged structure, devoted to show and social uses; but the humblest tent made—the *tente d'abri* or shelter tent of the French army—is also ridged in form. The *tente d'abri* affords sleeping accommodation for six men, and consists of a rope stretched over three low poles and fixed into the ground. Four separate squares of canvas buttoned together are thrown over the rope and pegged to the ground on each side so as to form a low ridge. Two other squares are used for covering the ends, being thrown over the slanting rope ends by which the poles are pegged to the ground. Each of the six men using the tent carries one of the squares of canvas besides his quota of the poles, rope, and pegs. The Gypsies and travelling tinkers of England have an equally unpretentious tent, which consists of a framework of hazel rods bent so as to form a series of low ridges, the ends being stuck into the ground, and over this frame blankets or other coverings are thrown and pegged down. The simplest, but at the same time the least convenient, of ordinary tents is the conical, consisting of a central pole with ropes and canvas radiating from it in an unbroken slope to the ground. This form, however, covers much ground in proportion to the accommodation it affords, as the space round the circumference is of little value. A tent, therefore, which has sides or a fall is a much more convenient structure. The counterpart of the conical is the pyramidal tent, the four equal sides sloping to the ground; and this form with a fall or sides makes the square tent, which is both convenient in shape and firm in structure. Small tents are also made, modified from the Arab form, with a central pole and two lower lateral poles. In the umbrella tent the roof is supported by a set of ribs which radiate from the pole, precisely as the ribs of an umbrella spread out from the stick. In the balloon expansion tent, invented in 1877 by Captain Newburgh Stewart, R.N., the use of tent pole, pegs, and ropes is entirely avoided, the canvas being supported by light ribs of elastic wood resting on the ground, and the structure is kept taut by hauling ropes descending from the apex and secured by a holdfast driven into the ground. When from the nature of the surface such fastening cannot be obtained, a heavy weight of any kind hung to the hauling rope is sufficient to moor the tent, and except in stormy weather the weight may be hung high up, thus leaving the whole interior of the tent clear. As further provision against stress of weather there are four iron holdfasts at the sides, which may be skewered into the ground by long iron pins. Captain Stewart claims that his tent possesses much greater stability and capacity than the ordinary army tent, that it is much more easily and expeditiously pitched and taken down, and that it is very much lighter. In the latter important respect he calculates that by the adoption of his pattern a regiment at present carrying eighty tents of the Indian service pattern would save no less than twenty tons of transport.

TEPLITZ, or **TÖPLITZ**, one of the most frequented watering-places in the north of Bohemia, is picturesquely situated about 30 miles south of Dresden, in the plain of the Biela, which separates the Erzgebirge from the Bohemian Mittelgebirge. The main interest of the little town centres in the bathing season, which reaches its height in August; and the arrangements for the convenience and amusement of visitors are very complete. There is a large curhaus, and numerous handsome bath-houses are situated both in Teplitz and in the immediately adjoining village of Schönau. The environs are laid out in pretty and shady gardens and promenades, the finest being in the park which surrounds the château of Prince Clary, the superior of the town. The other chief buildings are the Roman Catholic and Protestant churches, the Jewish synagogue with a conspicuous dome, and the theatre. The saline-alkaline springs of Teplitz, ten to twelve in number, ranging in temperature from 90° to 117° Fahr., are classed among what are called "indifferent" waters. Used until lately almost exclusively for bathing, they are prescribed for gout, rheumatism, and some scrofulous affections, and their reputed efficacy in alleviating the effects of gun-shot wounds had gained for Teplitz the sobriquet of "the warriors' bath." Military baths are maintained in the town by the Governments of Austria, Prussia, and Saxony, and there are also bath-houses for the poor. Teplitz is much visited for the after-cure, after Carlsbad and similar spas. The number of patients in 1883 was 6000 and the passing visitors were almost as numerous. The presence of a bed of lignite in the neighborhood has encouraged the industrial development of Teplitz, which carries on manufactures of cotton and woollen goods, india-rubber, chemicals, hardware, etc. In 1880 the united population of Teplitz and Schönau was 16,750.

The thermal springs are fabled to have been discovered as early as 762, but the first authentic mention of the baths occurs in the 16th century. The town is mentioned in the 12th century, the name being derived from a Slavonic word meaning "warm bath." Teplitz figures in the history of Wallenstein, and is also interesting as the spot where the monarchs of Austria, Russia, and Prussia first signed the triple alliance against Napoleon in 1813. It is a curious fact that on the day of the earthquake at Lisbon (1st November, 1755) the main spring at Teplitz ceased to flow for some minutes.

TERAMO, a town of Italy, capital of the province of Teramo (formerly Abruzzo Ulteriore I.) and an episcopal see, stands on the left bank of the Tordino where it is joined by the Vezzola, 12 miles from the coast and 876 feet above sea-level. It is connected by a branch line with Giulianova on the railway from Ancona to Brindisi. The picturesque valley of the Tordino is here dominated by the peaks of the Gran Sasso d'Italia (9522 feet). The town is traversed by one straight wide street with large houses, but for the most part it consists of narrow dirty lanes; the modern suburbs are good. The cathedral (1317–55) has been greatly modernized; the church of San Agostino is in the later Gothic style. The antiquities include remains of a gateway, a theatre, and baths, as well as numerous inscriptions. There are manufactures of wool and silk, and of straw hats and pottery. The population of the town in 1881 was 8634, with its suburbs 13,988 (commune, 20,309).

Teramo is the ancient *Interamna Prætutiana*, capital of the Prætutii. In the Middle Ages it was known as Aprutium (whence Abruzzo); the intermediate form of the present name was Teramne.

TERAPHIM (תרפים), a Hebrew word found only in the plural, which the Authorized Version sometimes simply transcribes (Judges xvii. 5, xviii. 14 *sq.*; Hosea iii. 4), but elsewhere translates by "images" (Gen. xxxi. 19 and often elsewhere), "image" (1 Sam. xix. 13), "idols" (Zech. x. 2), "idolatry" (1 Sam. xv. 23). The etymology of the word is quite obscure (see Gesenius, *Thesaurus*, p. 1519 *sq.*), but it appears that the teraphim were a kind of idols (Gen. xxxi. 30), with something of a human figure (1 Sam. xix. 13); and, though their use was condemned by the prophets (1 Sam. xv. 23; cp. 2 Kings xxiii. 24), they were long commonly used in popular worship, both domestic

(1 Sam. xix. 13, in the house of David and Michal) and public (Judges xviii.). They are associated with the ephod, which in this connection seems to mean a plated image, and Hosea speaks of ephod and teraphim as essential elements in the religious usages of northern Israel. Like the ephod, they were specially associated with divination, and in particular with the sacred lot (Zech. x. 2; Ezek. xxi. 21 [26]). From the last passage it appears that teraphim were used by the Babylonians as well as by the Hebrews. These statements and references cover all that is known about the teraphim; the fables of the rabbins are collected in Buxtorf, *Lex. Talmud.*, 2660 *sq.*

TERBURG, GERARD (1608–1681), subject painter, was born in 1608, at Zwolle, in the province of Overyssel, Holland. His father, also an artist, sent him to study in Rome, where he adopted a style distinguished by great finish and accuracy. He practiced for a time in Paris with much success, visited England, it is said, and then returned to Holland. In 1648 he was at Münster during the meeting of the congress which ratified the treaty of peace between the Spaniards and the Dutch, and executed his celebrated little picture, painted upon copper, of the assembled plenipotentiaries, — a work which, along with the Guitar Lesson, now represents the master in the national collection in London. At this time Terburg was invited to visit Madrid, where he received employment and the honor of knighthood from Philip IV. It is said that, in consequence of an intrigue, he was obliged to return to Holland. He seems to have resided for a time in Haarlem; but he finally settled in Deventer, where he became a member of the town council, as which he appears in the portrait now in the gallery of The Hague. He died at Deventer in 1681.

Terburg is excellent as a portrait painter, but still greater as a painter of *genre* subjects. He depicts with admirable truth the life of the wealthy and cultured classes of his time, and his work is free from any touch of the grossness which finds so large a place in Dutch art. His figures are well drawn and expressive in attitude; his coloring is clear and rich; but his best skill lies in his unequalled rendering of texture in draperies, which is seen to advantage in such pictures as the Letter in the Dutch royal collection, and in the Paternal Advice (known as the Satin Gown)—engraved by Wille—which exists in various repetitions at Berlin and Amsterdam, and in the Bridgewater Gallery. Terburg's works are rare; only about eighty have been catalogued.

TERCEIRA. See AZORES, vol. iii. p. 149.

TEREDO, a genus of Lamellibranchiate *Mollusca*, of the order *Isomya*, sub-order *Sinupallia*, family *Pholadacea* (see MOLLUSCA, vol. xvi. p. 713.) The animals included in this genus are commonly known as "ship-worms," and are notorious for the destruction which they cause in ships' timbers, the woodwork of harbors, and piles or other wood immersed for a long period in the sea. They inhabit long cylindrical holes, which they excavate in the wood, and usually occur in great numbers, crowded together so that often only a very thin film remains between the adjacent burrows. Each burrow is lined with a layer of calcareous substance secreted by the mollusc; this lining is not usually complete, but stops short a little distance from the inner end of the burrow, where the boring process continues to take place. In some burrows, however, the lining is complete, either because the animal has reached its full size or because some cause prevents it continuing its tunnel; in such cases the calcareous tube has a hemispherical termination. The burrows are usually driven in the direction of the grain of the wood, but not invariably so. When a knot or nail or the tube of a neighbor is reached, the course of the burrow is altered so as to bend round the obstruction. One burrow is never found to break into another.

The adult *Teredo*, when removed from its burrow and calcareous tube, is from a few inches to 3 feet in length, according to the species to which it belongs, and is cylindrical and worm-like in appearance. The anterior end, which lies at the bottom of the burrow, is somewhat enlarged and bears a pair of shells or valves, which are not connected by the usual ligament, but are widely separated dorsally. The valves are triangular in shape and very concave on the side which is in contact with the animal. In front their edges are widely separated, and the mantle tube, which is elsewhere closed, has here a slight median aperture, through which the short sucker-like foot can be protruded. The next portion of the body behind the shell-bearing part is naked, except for the shelly lining of the burrow, which is secreted by this part. Anteriorly this portion contains part of the body proper; posteriorly it forms a tube divided internally by a horizontal partition into two chambers. In the lower chamber are the elongated gill plates, which have the typical lamellibranchiate structure. In the upper chamber anteriorly is the rectum. A thick muscular ring terminates this region of the body, and bears two calcareous plates shaped like spades or battledores. The expanded parts of these plates are free and project backwards; the handle is fixed in a deep socket or pit lined by epidermis. These calcareous plates are called pallets (Fr. *palmules*). Behind the pallets the tubular body bifurcates, forming two siphons similar to those of other Lamellibranchs; the siphons can be contracted or expanded within wide limits of length. The principal organs of the body—stomach, heart, generative organs, and nephridia—are situated in the anterior part of the body, forming a visceral mass, which extends some distance behind the valves. The heart is above the intestine and not perforated by it. The two valves are connected by an anterior adductor muscle.

From its resemblance to *Pholas*, *Teredo* is placed by conchologists in the family *Pholadidæ*, among the *Isomya;* but it is still undecided which part of the body corresponds to the posterior adductor. According to Quatrefages, it is a muscular band passing transversely between the handles of the pallets. His discussion of this point is connected with another, namely, the nature of the long tubular portion of the body behind the valves. Deshayes limits the extent of the mantle to the part covered by the shell, and considers all the rest of the animal as formed by the siphons; the branchiæ and part of the other viscera in this view are contained in the siphons. Quatrefages argues that the siphons commence at the point where their retractor muscles are inserted, namely, at the muscular ring corresponding to the pallets. This reasoning is plausible; but it is difficult to accept the view that the retractor muscles of the siphons and the posterior adductor muscle are so closely connected as Quatrefages thinks; in other *Isomya* the retractors of the siphons and the posterior adductor are distinct and separate. Deshayes believes that the single adductor between the valves results from the fusion of the two muscles usually separate. Jeffreys believes that the posterior adductor is really present between the posterior parts of the valves; but the opinion of a conchologist on a question of morphology is not of very great weight. In other *Isomya* the visceral (parieto-splanchnic) ganglia are attached to the ventral surface of the posterior adductor. In *Teredo* these ganglia are situated at the posterior end of the body proper, some distance behind the shells, and immediately behind the generative organ. It is here probably that the rudiment of the posterior adductor, if it exists, is to be sought; or, if it does not exist, it is here that it originally was placed.

It is evident that the anatomy of *Teredo* has not yet been investigated from the point of view of modern morphology; but as far as can be judged at present the body proper extends back some distance behind the shells, to the posterior limit of the visceral mass. The part between this and the pallets is a tubular prolongation of the mantle chamber containing the extended gill laminæ, and beyond the pallets are the separate siphons. Besides the visceral ganglia a cerebral and a pedal pair are present. The stomach is provided with a large crystalline style. The function of the pallets is to form an operculum to the calcareous tube when the siphons are withdrawn into it. In some species the external or narrower end of the calcareous tube is provided with transverse laminæ projecting into the lumen; and in some the external aperture is divided by a horizontal partition into two, one for each siphon.

The *Teredo*, according to Quatrefages, is diœcious, though Gwyn Jeffreys believes it to be hermaphrodite. As in the case of the oyster, the ova are retained in the branchial chamber during the early stages of their development. The segmentation of the ovum is unequal, and leads to the formation of a gastrula by epibole. By the growth of a preoral lobe provided with a ring of cilia, and by the formation of a mouth and an anus, the trochosphere stage is reached. A pair of thin shells then appear on the sides of the larva, connected by a hinge on the dorsal median line, and the foot grows out between mouth and anus. By the time the larvæ "swarm," or leave the branchial cavity of the parent to live for a time as free-swimming pelagic larvæ, the valves of the shell have grown so large as to cover the whole of the body when the velum is retracted; the foot is also long, cylindrical, and flexible, and can be protruded far beyond the shell. The valves of the shell at this stage are hemispherical in shape, so that the whole larva when its organs are retracted is contained in a globular case.

Concerning the later changes of the larva and the method by which it bores into wood nothing or little is known from direct observation. Much has been written about the boring of this and other marine animals, but even yet the matter cannot be said to be satisfactorily elucidated. Osler, in a paper in *Phil. Trans.*, 1826, argued that the *Teredo* bores by means of its shells, fixing itself by the surface of the foot, which it uses as a sucker, and then rasping the wood with the rough front edges of the shell-valves. This view was founded on the similarity of the arrangement of the shells and muscles in *Teredo* to those occurring in *Pholas*, in which the method of boring described was actually observed. W. Thompson, in a paper in the *Edinb. New Phil. Journ.*, 1835, supported the view that the excavation is due to the action of a solvent secreted from the surface of the animal. Albany Hancock, again (*Ann. and Mag. Nat. Hist.*, vol. xv.), thinks that the excavating power of *Teredo* is due to silicious particles embedded in the anterior portion of the integument, in front of the valves. But the actual existence of either silicious particles or acid secretion has been denied by others. Jeffreys believes that the foot is the organ by which the animal burrows. In the larger number of Lamellibranchs the foot is doubtless a burrowing organ, and it is difficult to see how the limpet hollows out the rock to which it is attached if not by means of the surface of its foot. At the same time it is difficult to explain how the soft muscular foot can penetrate into hard wood. The process is of course slow, and Jeffreys supposes that particles are detached one by one from the moistened surface to which the foot is applied. In any case the valves are covered by an epidermis, which could scarcely be there if they were used in burrowing.

Teredo grows and burrows at an extremely rapid rate: spawning takes place in the spring and summer, and before the end of the year the animals are adult and their burrows of large size. Quatrefages relates that at Guipuzcoa (N. Spain) a ferry-boat was sunk accidentally in the spring, and was raised four months afterwards, when its timbers were already rendered useless by *T. pedicellata*. How long the animals live is not accurately known, but Quatrefages found that they nearly all perished in the winter. This cannot be generally the case, as the size of the tubes varies so greatly. In Holland their greatest ravages are made in July and August. Iron ships have nothing to fear from their attacks, and the copper sheathing now almost universally used protects wooden hulls. A great deal of loss is, however, caused by *Teredo* in harbor works and shipping stages, and the embankments in Holland are continually injured by it. The most efficient protection is afforded by large-headed nails driven in in close proximity. Soaking wood in creosote is not a certain safeguard; Jeffreys found at Christiania in 1863 that a large number of harbor piles previously soaked in creosote had been completely destroyed by *T. navalis*. Coal tar and the silicate of lime, used for coating stonework, have been suggested as protective coverings, but they do not seem to have been adequately tested.

Species of *Teredo* occur in all seas. The animal was known to the ancients and is mentioned by Theophrastus, Pliny, and Ovid. In 1715 it is mentioned by Valisnieri, in 1720 by Deslandes. In 1733 great attention was drawn to it on account of the discovery that the wooden dykes of Holland were being rapidly destroyed by ship-worms, and that the country was in danger of inundation. Three treatises were published concerning the animal, by P. Massuet, J. Rousset, and Godfrey Sellius. The work of the last-named, which was the best, described the anatomy of the creature and showed that its affinities were with bivalve molluscs. The truth of Sellius's view was not grasped by Linnæus, who placed *Teredo* together with *Serpula* in the genus *Dentalium*; but its proper position was re-established by Cuvier and Lamarck. Adanson, unaware of the work of Sellius, in 1757 believed himself to be the first to discover the molluscan affinities of *Teredo*. It will not be necessary to give here a definition of the genus taken from any systematist; it will be sufficient to point out that the long cylindrical body with its two small anterior polygonal valves, the absence of a ligament and accessory valves, the muscular ring into which are inserted the calcareous pallets, and the continuous calcareous tube lining the hole bored by the animal are the diagnostic features.

Jeffreys, in his *British Conchology*, gives the following species as British: *Teredo norvegica*, Spengler; *T. navalis*, Linn.; *T. pedicellata*, Quatrefages; *T. megotara*, Hanley. *T. norvegica* occurs chiefly on the west coast of Great Britain. It was taken by Thompson at Portpatrick in Wigtownshire, and occurred in Jeffreys's time in abundance at Milford Haven. This species has been described by Gmelin and a number of British authors as *T. navalis*, Linn. It is distinguished by having the base of the pallets simple, not forked, and the tube semi-concamerated at its narrower posterior end. The length does not usually exceed a foot. It is the *T. navium* of Sellius. *T. navalis* has been identified from the figures of Sellius, to which Linnæus referred: Sellius called it *T. marina*. It occurs on all the western and southern coasts of Europe, from Christiania to the Black Sea, and is the species which causes so much damage to the Dutch embankments. The pallets of this species are small and forked, and the stalk is cylindrical. The tube is simple and not chambered at its narrow end. *T. pedicellata* was originally discovered by Quatrefages in the Bay of Los Pasages on the north coast of Spain; it has also been found in the Channel Islands, at Toulon, in Provence, and in Algeria. In *T. megotara* the tube is simple and the pallets like those of *T. norvegica*; it occurs at Shetland and Wick, and also on the western shore of the Atlantic, where its range extends from Massachusetts to South Carolina. *T. malleolus*, Turton, and *T. bipinnata*, Turton, belong to the West Indies, but are often drifted in floating timber to the coasts of Europe. Other occasional visitants to the British shores are *T. excavata, bipartita, spatha, fusticulus, cucullata*, and *fimbriata*. These were described by Gwyn Jeffreys in *Ann. and Mag. Nat. His.*, 1860. *T. fimbriata* is stated to be a native of Vancouver's Island. A kind of ship-worm, the *Nausitora dunlopei* of Perceval Wright, has been discovered in India, 70 miles from the sea, in a stream of perfectly fresh water, namely, the river Kumar, one of the branches of the Ganges. *T. coniformis*, Lam., is found burrowing in the husks of cocoa-nuts and other woody fruits floating in the tropical seas; its tubes are extremely crooked and contorted for want of space. Fossil wood and palm-fruits of Sheppey and Brabant are pierced in the same way.

Twenty-four fossil species have been recognized in the Lias and succeeding beds of Europe and the United States. The sub-genus *Teredina*, Lam., is a fossil of the Eocene of Great Britain and France.

Literature.—See, besides the works already mentioned, Godfrey Sellius, *Historia Naturalis Teredinis seu Xylophagi Marini*, 1733; Adanson, *Histoire Naturelle du Sénégal*, Paris, 1757; Quatrefages, *Annales des Sci. Nat.*, 1848–50; Forbes and Hanley, *Brit. Mollusca*, 1853; B. Hatschek, *Entwicklung v. Teredo; Arbeiten aus dem Zool. Inst. Wien*, 1880; Deshayes, *Mollusques d'Algérie*; Sir E. Home, "Anatomy of *Teredo*," in *Phil. Trans.*, vol. xcvi.; Frey and Leuckart, *Beiträge zur Kenntniss wirbelloser Thiere*, 1847; Woodward, *Manual of Mollusca*, London, 1851. (J. T. C.)

TEREK (Russ. *Terskaya oblast*), a Russian government of Caucasia, situated to the north of the main Caucasus chain. It is bounded by Stavropol on the N., by the Caspian Sea and Daghestan on the E., by Tiflis and Kutais on the S., and by Tchernomorsk and Kuban on the W. It has an area of 23,548 square miles. From Mt. Elburz to Kazbek the southern boundary coincides with the main snow-covered range of the Caucasus and thus includes its highest peaks; further east it follows a sinuous line so as to embrace the secondary chains and their ramifications. Nearly one-third of the area is occupied by hilly tracts, the remainder being undulating and flat land belonging to the depression of the Terek; one-half of this last, on the left bank of the river, is occupied by sandy deserts, salt clay steppes, and arid stretches unsuited for cultivation. Granites, syenites, diorites, and Palæozoic schists constitute the nucleus of the Caucasus mountains; Jurassic and Cretaceous formations rise to great heights in the secondary chains; and a series of Tertiary formations, covered by Quaternary deposits, cover a wide area in the prairies and steppes. A group of mineral springs occurs about PYATIGORSK (*q.v.*).

The climate is continental. The mean annual temperatures are 49.6° Fahr. at Pyatigorsk (1850 feet above the sea; January 39°, July 70°) and 47.7° at Vładikavkaz (2230 ft.; January 23°, July 69°), but frosts a few degrees below zero are not uncommon. The mountain slopes receive an abundance of rain (37 in.), but the steppes suffer much from drought (rainfall between 10 and 20 in.). Nearly the whole of the government belongs to the drainage area of the Terek, but the northwest corner is watered by the upper tributaries of the Kuma. The Terek rises at the height of about 8000 feet in the glaciers of the Kazbek on the southern slope of the main chain of the Caucasus, which it pierces by the Darial gorge to the south of Vładikavkaz after having received several *dons* or streams (Res, Guzel, Fiag, Ar). In 53 miles it descends nearly 6000 feet. A few miles above Vładikavkaz it is 2068 feet above sea-level, at Mozdok 441 feet, and it is 29 feet below the Black Sea at Kizlyar. From Vładikavkaz it pursues a northeasterly direction before taking its eastward course; it seems most probable that at a recent epoch (Post-Pliocene) it joined the Kuma and perhaps the Manytch instead of flowing into the Caspian. In the lower part of its course it flows at a higher level than that of the neighboring plains, and is kept in its bed by dams. Inundations are frequent and cause great destruction. The delta begins at Dubovka (50 miles from the Caspian), and at this part the river frequently changes its bed. The Old Terek is no longer navigable, the chief current being directed northwards into the New Terek. Several canals made by the Cossacks supply water for the irrigation of the neighboring fields. Its chief tributaries are the Sunja on the right, and the Tcherekh, the Baksan, and the Malka, in its upper course, on the left. The population of the government in 1884 was 615,660; of 606,500 inhabitants returned in 1883, 238,230 were Little and Great Russians, 1230 Georgians, 18,500 Armenians, 4300 Germans, 2570 Poles, 4780 Jews, 23,630 Ossets, 194,480 Tchetchens and Ingushis, 72,160 Kabardians, 9130 mountaineers of the Avarian stem, 25,360 Kumyks, 1770 Tatars, 6270 Nogais, 2470 Kalmucks, and 1620 Persians. Out of these 239,500 were reckoned as belonging to the Greek Orthodox Church, 336,460 were Mussulmans, 17,730 Gregorian Armenians, and the remainder Protestants, Catholics and Jews. Owing to the great fertility of the soil in the well-watered districts, agriculture is the chief occupation. In 1882, the crops, although below the average, yielded 967,000 quarters of corn, 268,000 bushels of potatoes, 6,750,000 gallons of wine, and tobacco to the value of £18,000 [$87,480]. Cattle breeding is extensively carried on in the steppes, and there were in the same year 118,630 horses, 582,800 cattle, and 1,226,400 sheep; murrains, however, are frequent, and cause great loss. Manufactures occupy only 3371 persons, and their yearly production hardly reaches £300,000 in value. Petty trades are rapidly spreading in the villages. Trade suffers from want of good roads. The railway from Russia to the Caucasus has not yet (1887) got beyond Vładikavkaz. The military and other chief roads have an aggregate of only 1300 miles. The exports are limited to corn, wine, cattle, and some raw produce.

The government is divided into six districts, the chief towns of which, with their populations in 1883, were Vładikavkaz (32,340), the capital, Georgievsk (4250) Groznyi (6280), Kizlyar (8780), Mozdok (8380), and Pyatigorsk (11,120).

TERENCE. P. Terentius Afer (185?–159 B.C.) holds a unique position among Roman writers. No writer in any literature has gained so great a reputation who has contented himself with so limited a function. He lays no claim to the position of an original artist painting from life or commenting on the results of his own observation. His art has no relation to his own time or to the country in which he lived. The chief source of interest in the fragmentary remains of Nævius, Ennius, Pacuvius, Accius, and Lucilius is their relation to the national and moral spirit of the age in which they were written. Plautus, though, like Terence, he takes the first sketch of his plots, scenes, and characters from the Attic stage, is yet a true representative of his time, a genuine Italian, writing before the genius of Italy had learned the restraints of Greek art. The whole aim of Terence was to present a faithful copy of the life, manners, modes of thought and expression which had been drawn from reality a century before his time by the writers of the New Comedy of Athens. The nearest parallel to his literary position may be found in the aim which Virgil puts before himself in his *Bucolics.* He does not seek in that poem to draw Italian peasants from the life, but to bring back the shepherds of Theocritus on Italian scenes. Yet the result obtained by Virgil is different. The charm of his pastorals is the Italian sentiment which pervades them. His shepherds are not the shepherds of Theocritus, nor are they in any sense true to life. The extraordinary result obtained by Terence is that, while he has left no trace in any of his comedies of one sketching from the life by which he was surrounded, there is perhaps no more truthful, natural, and delicate delineator of human nature, in its ordinary and more level moods, within the whole range of classical literature. His permanent position in literature is due, no doubt, to the art and genius of Menander, whose creations he has perpetuated, as a fine engraver may perpetuate the spirit of a great painter whose works have perished. But no mere copyist or verbal translator could have attained that result. Though without claims to creative originality, Terence must have had not only critical genius, to enable him fully to appreciate and identify himself with his originals, but artistic genius of a high and pure type. The importance of his position in Roman literature consists in this, that he was the first writer who set before himself a high ideal of artistic perfection, and was the first to realize that perfection in style, form, and consistency of conception and execution. Living in the interval between Ennius and Lucilius, whose original force and genius survive only in rude and inartistic fragments, he produced six plays, which have not only reached our time in the form in which they were given to the world, but have been read in the most critical and exacting literary epochs, and still may be read without any feeling of the need of making allowance for the rudeness of a new and undeveloped art.

While his great gift to Roman literature is that he first made it artistic, that he imparted to "rude Latium" the sense of elegance, consistency, and moderation, his gift to the world is that through him it possesses a living image of the Greek society in the 3d century B.C., presented in the purest Latin idiom. Yet Terence had no affinity by birth either with the Greek race or with the people of Latium. He was more distinctly a foreigner than any of the great classical writers of Rome. He lived at the meeting-point of three distinct civilizations,—the mature, or rather decaying, civilization of Greece, of which Athens was still the centre; that of Carthage, which was so soon to pass away and leave scarcely any vestige of itself; and the nascent civilization of Italy, in which all other modes were soon to be absorbed. Terence was by birth a Phœnician, and was thus perhaps a fitter medium of connection between the genius of Greece and that of Italy than if he had been a pure Greek or a pure Italian; just as in modern times the Jewish type of genius is sometimes found more detached from national peculiarities, and thus more capable of reproducing a cosmopolitan type of character than the genius of men belonging to the other races of Europe.

Our knowledge of the life of Terence is derived chiefly from a fragment of the lost work of Suetonius, *De Viris Illustribus*, preserved in the commentary of Donatus. Confirmation of some of the statements contained in the *Life* is obtained from later writers and speakers, and also from the prologues to the different plays, which at the same time throw light on the literary and personal relations of the poet. These prologues were among the original sources of Suetonius; but he quotes or refers to the works of various grammarians and antiquarians—Porcius Licinus, Volcatius Sedigitus, Santra, Nepos, Fenestella, Q. Cosconius—as his authorities. The first two lived within a generation or two of the death of Terence, and the first of them shows a distinct animus against him and his patrons. But, notwithstanding the abundance of authorities, there is uncertainty as to both the date of his birth and the place and manner of his death. The doubt as to the former arises from the discrepancy of the MSS. His last play, the *Adelphi*, was exhibited in 160 B.C. Shortly after its production he went to Greece, being then, according to the best MSS., in his twenty-fifth ("nondum quintum atque vicesimum egressus[1] annum"), according to inferior MSS., in his thirty-fifth year. This uncertainty is increased by a discrepancy between the authorities quoted by Suetonius. Cornelius Nepos is quoted for the statement that he was about the same age as Scipio (born 185 B.C.) and Lælius, while Fenestella, an antiquarian of the later Augustan period, represented him as older. As the authority of the MSS. coincides with that of the older record, the year 185 B.C. may be taken as the most probable date of his birth. In the case of an author drawing originally from life, it might seem improbable that he should have written six comedies, so true in their apprehension and delineation of various phases of human nature, between the ages of nineteen and twenty-five. But the case of an imitative artist, reproducing impressions derived from literature, is different; and the circumstances of Terence's origin and early life may well have developed in him a precocity of talent. His acknowledged intimacy with Scipio and Lælius and the general belief that they assisted him in the composition of his plays are more in accordance with the statement that he was about their own age than that he was ten years older. Terence, accordingly, more even than Catullus, Tibullus, or Lucan, is to be ranked among those poets who are the "inheritors of unfulfilled renown." He is said to have been born at Carthage, brought to Rome as a slave, and carefully educated in the house of M. Terentius Lucanus, by whom he was soon emancipated. A difficulty was felt in ancient times as to how he originally became a slave, as there was no war between Rome and Carthage between the Second and Third Punic Wars, and no commercial relations between Africa and Italy till after the destruction of Carthage. But there was no doubt as to his Phœnician origin. He was admitted into the intimacy of young men of the best families, such as Scipio, Lælius, and Furius Philus, and he enjoyed the favor of older men of literary distinction and official position, such as C. Sulpicius Gallus, Q. Fabius Labeo, and M. Popillius. He is said to have owed the favor of the great as much to his personal gifts and graces as to his literary distinction; and in one of his prologues he declares it to be his ambition, while not offending the many, to please the "boni."

Terence's earliest play was the *Andria*, exhibited in 166 B.C., when the poet could have been only about the age of nineteen. A pretty, but probably apocryphal, story is told of his having read the play, before its exhibition, to Cæcilius (who, after the death of Plautus, ranked as the foremost comic poet), and of the generous admiration of it manifested by Cæcilius. A similar instance of the recognition of rising genius by a poet whose own day was past is found in the account given of the visit of Accius, on his journey to Asia, to the veteran Pacuvius. The next play exhibited by Terence was the *Hecyra*, first produced in 165, but withdrawn in consequence of the bad reception which it met with, and afterwards reproduced in 160. The *Heauton-timoroumenos* appeared in 163, the *Eunuchus* and *Phormio* in 161, and the *Adelphi* in 160 at the funeral games of L. Æmilius Paulus.

After bringing out these plays Terence sailed for Greece, either to escape from the suspicion of publishing the works of others as his own, or from a desire to obtain a more intimate knowledge of that Greek life which had hitherto been known to him only in literature, and which it was his professed aim to reproduce in his comedies. The latter is the more probable motive, and we recognize in this the first instance of that impulse to visit the scenes familiar to them through literature which afterwards acted on many of the great writers of Rome. From this voyage to Greece Terence never returned. According to one account he was lost at sea, according to another he died at Stymphalus in Arcadia, and according to a third at Leucadia, from grief at the loss by shipwreck of his baggage, containing a number of new plays which he had translated from Menander. The old grammarian quoted by Suetonius states that he was ruined in fortune through his intimacy with his noble friends. Another account speaks of him as having left behind him property consisting of gardens, to the extent of twenty acres, close to the Appian Way. It is further stated that his daughter was so well provided for that she married a Roman knight.

The tone of the prologues to Terence's plays is for the most part apologetic, and indicates a great sensitiveness to criticism. He constantly speaks of the malevolence and detraction of an older poet, whose name is said to have been Luscius Lavinius or Lanuvinus. The chief charge which his detractor brings against him is that of *contaminatio*, the combining in one play of scenes out of different Greek plays. Terence justifies his practice by that of the older poets, Nævius, Plautus, Ennius, whose careless freedom he follows in preference to the "obscura diligentia" of his detractor. He recriminates upon his adversary as one who, by his literal adherence to his original, had turned good Greek plays into bad Latin ones. He justifies himself from the charge of plagiarizing from Plautus and Nævius. In another prologue he contrasts his own treatment of his subjects with the sensational extravagance of others. He meets the charge of receiving assistance in the composition of his plays by claiming, as a great honor, the favor which he enjoyed with those who were the favorites of the Roman people.

We learn from these prologues that the best Roman literature was ceasing to be popular, and had come to rely on the patronage of the great. A consequence of this change of circumstances was that comedy was no longer national in character and sentiment, but had become imitative and artistic. The life which Terence represents is that of a well-to-do-citizen class whose interests are commonplace, but whose modes of thought and speech are refined, humane, and intelligent. His characters are finely delineated and discriminated rather than boldly conceived, as they are in Plautus. Delicate irony and pointed epigram take the place of broad humor. Love, in the form of pathetic sentiment rather than of irregular passion, is the chief motive of his pieces. His great characteristics are humanity and urbanity, and to this may be attributed the attraction which he had for the two chief representatives of these qualities in Roman literature—Cicero and Horace. It was through the comedies of Terence that the finer influences of the Epicurean philosophy—the friendliness, the tolerance, the consideration for the feelings of others, inferiors as well as equals, inculcated by that philosophy—entered into Roman life and literature. The dissolving influence of that school on the severer personal morality of the older Roman republic also entered into Roman life through the same medium. But it was a great gain to the strong but rude Roman character to learn, as it could from every line of Terence, lessons not only of courtesy and social amenity but of genuine sympathy and consideration.

Terence's pre-eminence in art was recognized by the critics of the Augustan age:

> "Vincere Cæcilius gravitate, Terentius arte."

The art of his comedies consists in the clearness and simplicity with which the situation is presented and developed, and in the consistency and moderation with which his various characters play their part. But his great attraction to both ancient and modern writers has been the purity and charm of his style, whether employed in narrative or dialogue. This charm he derived from his familiarity with the purest Latin idiom, as it was habitually used in the intimate intercourse of the best Roman families, and also with the purest Attic idiom, as it had been written and spoken a century before his own time. The fine Attic flavor is more perceptible in his Latin than in the Greek of his contemporaries. He makes no claim to the creative exuberance of Plautus, but he is entirely free from his extravagance and mannerisms. The superiority of his style over that of Lucilius, who wrote his satires a generation later, is almost immeasurable. The best judges and the greatest masters of style in the best period of Roman literature were his chief admirers in ancient times. Cicero frequently reproduces his expressions, applies passages in his plays to his own circumstances, and refers to his personages as typical representations of character.[1] Julius Cæsar characterizes him as "puri sermonis amator." Horace, so depreciatory in general of the older literature, shows his appreciation of Terence by the frequent reproduction in his *Satires* and in his *Odes* of his language and his philosophy of life. Quintilian applies to his writings the epithet "elegantissima," and in that connection refers to the belief that they were the work of Scipio Africanus. His works were studied and learned by heart by the great Latin writers of the Renaissance, such as Erasmus and Melanchthon; and Casaubon, in his anxiety that his son should write a pure Latin style, inculcates on him the constant study of Terence. Montaigne applies to him the phrase of Horace:

---

[1] Ritschl reads *ingressus*, which would make him a year younger.

> "Liquidus puroque simillimus amni."

He speaks of "his fine expression, elegancy, and quaintness," and adds, "he does so possess the soul with his graces that we forget those of his fable."[2] It is among the French, the great masters of the prose of refined conversation, that his merits have been most appreciated in modern times. Sainte-Beuve, in his *Nouveaux Lundis*, devotes to him two papers of delicate and admiring criticism. He quotes Fénelon and Addison, "deux esprits polis et doux, de la même famille littéraire," as expressing their admiration for the inimitable beauty and naturalness of one of his scenes. Fénelon is said to have preferred him even to Molière. Sainte-Beuve calls Terence the bond of union between Roman urbanity and the Atticism of the Greeks, and adds that it was in the 17th century, when French literature was most truly Attic, that he was most appreciated. M. Joubert is quoted[3] as applying to him the words "Le miel attique est sur ses lèvres; on croîrait aisément qu'il naquit sur le mont Hymette."

The most famous edition of Terence is that of Bentley, published in 1726. More recent editions are those of Parry, in the *Bibliotheca Classica*, and of W. Wagner. The text has been edited by A. Flickeisen in the Teubner series of classics. A number of editions of the separate plays have been published recently both in England and in Germany. (W. Y. S.)

TERESA, St. See Theresa, St.

TERLIZZI, a town of Italy, in the province of Bari, and 20 miles west from that town, stands in the midst of a fertile plain. It has a castle which at one time was very strong and occasionally resorted to by the emperor Frederick II. and afterwards by the Aragonese sovereigns. The walls and towers of the town still remain, but the fosse has been turned into boulevards. Terlizzi has a considerable trade, chiefly in the wine and fruit of the district. The population of the town in 1881 was 20,442 (commune, 20,592).

TERM (from the Latin *terminus*) in English law is used in two senses, the idea common to both being that of a limited and certain period of time.

(1) It denotes (or rather did denote), a fixed time during which the courts are open for legal proceedings. Terms in this sense affected only what used to be called the superior courts,—that is, the Queen's Bench, Common Pleas, and Exchequer. They were originally the leisure seasons of the year which were not occupied by great feasts or fasts of the church or by agriculture. Their origin is no doubt to be traced back to the legislation of the early Christian emperors, the principle being adopted in England through the influence of ecclesiastical judges, and still surviving in the universities and Inns of Court. Terms were regulated by many Acts of parliament, the effect of which was to confine to a comparatively short period the time during which the courts could sit *in banco*,—that is, for the decision of questions of law as distinguished from the decision of questions of fact. There were four terms, Hilary, Easter, Trinity, and Michaelmas, the average duration of each being about three weeks. All legislation on the subject previous to 1873 is now merely of historical interest, for by the Judicature Act of that year the division of the year into terms was abolished so far as related to the administration of justice.

(2) It denotes the time during which an interest in an estate for life or for years is enjoyed, also the interest itself, because such an interest must determine at a definite time. If the interest be for life, it is an estate of freehold; if for years, only a personal interest in real estate, and so personalty, even though the length of the term—for instance, 1000 years—may far exceed in duration any possible life estate. A term of years is of two kinds—the first that created by an ordinary lease reserving a rent, as of a house or a building lease; the second that created by a settlement or a will, usually without rent reserved, for the purpose of securing payment of money, such as portions to younger children, by the owner of the land. Both kinds have been considerably affected by recent legislation. For instance, the Conveyancing Act, 1881, enables a mortgagor or mortgagee in possession to make certain leases. Before 1845 provision was always made in conveyances for keeping on foot a term to attend the inheritance, as it was called,—that is, for assigning the remainder of a term to trustees for the protection of the owner of the property against rent-charges or other incumbrances created subsequently to the term, although the term had been satisfied,—that is, the purpose for which the term had been created had been fulfilled. By 8 and 9 Vict. c. 112 the assignment of satisfied terms was rendered unnecessary. The Conveyancing Acts, 1881 and 1882, give power to enlarge the unexpired residue of a long term in certain cases into the fee simple.

In Scotland terms are the days at which rent or interest is payable. They are either legal or conventional: the legal are Whitsunday and Martinmas; the conventional are fixed by agreement between the parties. A recent Act (44 and 45 Vict. c. 39) makes uniform the law as to removal terms in burghs. Terms as times of court sittings were defined by 6 Anne c. 53, which fixed four terms—Martinmas, Candlemas, Whitsuntide, and Lammas—for the now obsolete Court of Exchequer. By 19 and 20 Vict. c. 56, s. 26, the winter and summer sittings of the Court of Sessions are to be held to correspond with the Exchequer terms.

TERMINI, or Termini Imerese (*Thermæ Himerenses*), a town on the north coast of Sicily, at the mouth of a river of the same name, in the province of Palermo, and 23 miles east-southeast of that town. None of its modern buildings are of any special interest; in the Piano de San Giovanni above the town the substructure of a Roman villa has been excavated, and there are also traces of an amphitheatre. Termini is one of the busiest provincial towns of Sicily; the surrounding district being exceedingly fertile and the harbor good, there is a considerable export trade in grain, fruit, tartar, and other products. The macaroni of Termini is in high repute. The tunny and sardine fisheries are extensive, and there is a school of navigation. The warm saline springs (110° Fahr.), sung by Pindar, are still largely resorted to, there being a well-appointed bath establishment, founded by Ferdinand I. The population of the town in 1881 was 22,370, with its suburbs 22,733 (commune, 23,148).

For the ancient history of Termini see Himera. The castle of Termini, which Robert of Naples besieged in vain in 1338, was destroyed in 1860.

TERMITES. See Ant, vol. ii. p. 88.

[3] By E. Negrette, in his *Histoire de la Littèrature Latine.*

TERN (Norsk *Tærne*, *Tenne*, or *Tende*; Swedish *Tärna*; Dutch *Stern*[1]), the name now applied generally to a group of sea-birds, the *Sterninæ* of modern ornithology, but, according to Selby, properly belonging, at least in the Farne Islands, to the species known by the book-name of Sandwich Tern, all the others being those called Sea-Swallows—a name still most commonly given to the whole group throughout Britain from their long wings, forked tail, and marine habit. In Willughby's *Ornithologia* (1676), however, the word Tern is used for more than one species, and, though it does not appear in the older English dictionaries, it may well have been from early times as general a name as it is now.

Setting aside those which are but occasional visitors to the British Islands, six species of Terns may be regarded as indigenous, though of them one has ceased from ordinarily breeding in the United Kingdom, while a second has become so rare and regularly appears in so few places that mention of them must for prudence sake be avoided. This last is the beautiful Roseate Tern, *Sterna dougalli*; the other is the Black Tern, *Hydrochelidon nigra*, belonging to a genus in which the toes are only half-webbed, of small size and dark leaden-gray plumage. It is without doubt the *Sterna* of Turner, and in former days was abundant in many parts of the fen country,[2] to say nothing of other districts. Though nearly all its ancient abodes have been drained, and for its purposes sterilized these many years past, not a spring comes but it shows itself in small companies in the eastern counties of England, evidently seeking a breeding-place. All around the coast the diminution in the numbers of the remaining species of Terns within the last 50 years is no less deplorable than demonstrable.

The Sandwich Tern, *S. sandvicensis* or *S. cantiaca*—named from the place of its discovery, though it has long since ceased to inhabit that neighborhood—is the largest of the British species, equalling in size the smaller Gulls and having a dark-colored bill tipped with yellow, and dark legs. Through persecution it has been exterminated in all its southern haunts, and is become much scarcer in those to which it still resorts. It was, however, never so abundant as its smaller congeners, the so-called Common and the Arctic Tern,—two species that are so nearly alike as to be beyond discrimination on the wing by an ordinary observer, and even in the hand require a somewhat close examination.[3] The former of these has the more southern range, and often affects inland situations, while the latter, though by no means limited to the Arctic circle, is widely distributed over the north and mostly resorts to the seacoast. Yet there are localities where, as on the Farne Islands, both meet and breed, without occupying stations apart. The minute diagnosis of these two species cannot be briefly given. It must suffice here to state that the most certain difference, as it is the most easily recognizable, is to be found in the tarsus, which in the Arctic Tern is a quarter of an inch shorter than its kinsman. The remaining native species is the Lesser Tern, *S. minuta*, one of the smallest of the genus and readily to be distinguished by its permanently white forehead. All the species already mentioned, except the Black Tern, have much the same general coloration—the adults in summer plumage wearing a black cap and having the upper parts of the body and wings of a more or less pale gray, while they are mostly lighter beneath. They generally breed in association, often in the closest proximity—their nests, containing 3 eggs at most, being made on the shingle or among herbage. The young are hatched clothed in variegated down, and remain in the nest for some time. At this season the parents are almost regardless of human presence and expose themselves freely.

At least half-a-dozen other species have been recorded as occurring in British waters, and among them the Caspian Tern, *S. caspia*, which is one of the largest of the genus and of wide distribution, though not breeding nearer to the shores of England than on Sylt and its neighboring islands, which still afford lodging for a few pairs. Another, the Gull-billed Tern, *S. anglica*, has also been not unfrequently shot in England. All these species are now recognized, though the contrary was once maintained, as inhabitants of North America, and many go much further.

An excellent synopsis of the Sub-family *Sterninæ* has been given by Mr. Howard Saunders in the Zoological *Proceedings* (1876, pp. 638–672). He recognizes 5 genera—*Hydrochelidon* (with 3 species), *Sterna* (with 38), *Nœnia*, a very aberrant form consisting of but one species, the Inca Tern, peculiar to the western coast of South America, and *Gygis*, composed of 2 species of purely white birds and restricted to the southern hemisphere; his fifth genus is *Anous*, to which belong the various species of NODDY (vol. xvii. p. 544). Often confounded with these last are the two species called in books Sooty Terns (*S. fuliginosa* and *S. anæstheta*), but by sailors "Egg-birds" or "Wide-awakes" from their cry. These crowd at certain seasons in innumerable multitude to certain islands within the tropics, where they breed, and the wonderful assemblage at present known as "Wide-awake fair" on the island of Ascension has been more or less fully described from very ancient times. Dampier in his voyage to New Holland in 1699 particularly described and figured the Sooty Tern (*Voyages*, iii. p. 142), discriminating it from the Noddy, from which it had not before been distinguished. (A. N.)

TERNATE, a small island in the East Indian Archipelago, off the west coast of JILOLO (*q.v.*), in 0° 48′ N. lat. and 127° 19′ E. long. It is nearly circular in form, with an area of about 25 square miles, and consists almost entirely of a very remarkable volcano (5600 feet) formed of three superimposed cones. Frequent and destructive eruptions have taken place. Cocoanuts, sago, tobacco, cotton, sulphur, and saltpetre are the chief productions of the island. The clove, which had been extirpated by the early Dutch rulers to enhance its value by restricting its cultivation to the Banda Islands, Amboyna, etc., is beginning again to be grown, as also is the nutmeg. The inhabitants are nearly all Mohammedan Malays. The town of Ternate, with a population of about 9000, is the seat of a native sultan and of a Dutch resident; the harbor is commanded by a fort. The residency, which includes a part of the eastern coast of Celebes (see CELEBES), the greater part of Jilolo, and numerous smaller islands, has an area of 26,900 square miles and a population estimated at about 290,000.

TERNI, a town of Italy, in the province of Perugia, is situated in the fertile valley of the Nera, between two branches of that river, about 5 miles below the point where it is joined by the Velino. It has a station, three-quarters of a mile off, on the railway line between Rome and Ancona, 69 miles to the north of the former city and 19 south by west from Spoleto. Terni is an episcopal see, and the seat of a sub-prefecture and a chamber of commerce. Its public buildings include the cathedral (17th century), the church of S. Francesco (partly dating from the 13th century), a gymnasium, and a theatre. Terni manufactures leather and cloth, and has some trade in wine and silk. For the traveller its chief interest lies in its antiquities (remains of an amphitheatre of the time of Tiberius, a temple, a theatre, baths, and numerous inscriptions) and in the proximity of the falls of Velino (*Cascate delle Marmore*). Alike in volume and in beauty these take a very high place among European waterfalls; the cataract has a total descent of about 650 feet, in three leaps of 65, 330, and 190 feet respectively. They owe their origin to M'. Curius Dentatus, who in 272 B.C. first opened an artificial channel by which the greater part of the Lacus Velinus in the valley below Reate was drained. The population of the town in 1881 was 9415, with its suburbs 10,371 (commune, 15,853).

---

[1] "Starn" was used in Norfolk in the 19th century as a name for the bird commonly known as the Black Tern, thus confirming Turner, who, in 1544, describes what seems to have been the same species as "nostrati lingua sterna appellata." In at least one instance the word has been confounded with one of the old forms of the modern STARLING (vol. xxii. p. 474–5). To Turner's name, repeated by Gesner and other authors, we owe the introduction by Linnæus of *Sterna* into scientific nomenclature. "Ikstern" is another Dutch form of the word.

[2] It was known there as Carr-Swallow, Carr-Crow (corrupted into "Scarecrow"), and Blue Dar (*qu.* = Daw ?).

[3] Linnæus's diagnosis of his *Sterna hirundo* points to his having had an "Arctic" Tern before him; but it is certain that he did not suspect that specific appellation (already used by other writers for the "Common" Tern) to cover a second species. Some modern authorities disregard his name as being insufficiently definite, and much is to be said for this view of the case. Undoubtedly "*hirundo*" has now been used so indiscriminately for one species or the other as to cause confusion, which is perhaps best avoided by adopting the epithets of Naumann (*Isis*, 1819, pp. 1847, 1848), who, acting on and confirming the discovery of Nitzsch (who first detected the specific difference), called the southern species *S. fluviatilis* and the northern *S. macrura*. Temminck's name *S. arctica* applied to the latter a year later has been most generally used for it, notwithstanding.

Terni is the ancient *Interamna* ("inter amnes"), originally belonging to Umbria and founded, according to a local tradition, in the year 672 B.C. It early became a flourishing municipium, and it did not permanently suffer through being portioned out among his soldiers by Sulla. Its inhabitants had frequent litigations and disputes with their neighbors at Reate in connection with the regulation of the Velinus, the waters of which are so strongly impregnated with carbonate of lime that by their deposits they tend to block up their own channel. The first interference with its natural course was that of M'. Curius Dentatus already referred to. In 54 B.C. the people of Reate appealed to Cicero to plead their cause in an arbitration which had been appointed by the Roman senate to settle disputes about the river, and in connection with this he made a personal inspection of Lake Velinus and its outlets. In the time of Tiberius there was a project for regulating the river and its outlets from the lake, against which the citizens of Interamna and Reate energetically and successfully protested (Tac., *Ann.*, i. 79). Similar questions arose as the river formed fresh deposits during the Middle Ages and during the 15th and 16th centuries. A branch of the Via Flaminia passed from Narnia to Forum Flaminii, and is given instead of the direct line in the Antonine and Jerusalem itineraries. The emperor Tacitus and his brother Florianus were probably natives of Interamna, which also has been claimed as the birthplace of Tacitus the historian, but with less reason. Terni was the scene of the defeat of the Neopolitans by the French on 27th November, 1798.

TERPANDER, a Lesbian poet and musician, settled in Sparta about the end of the Second Messenian War (668 B.C.). According to some accounts he was invited thither by command of the Delphian oracle to compose the difference which had arisen between different classes in the state. His innovations in music were considered to have inaugurated a new era of musical art in Greece; but we are very imperfectly informed as to their nature. On the strength of a fragment (No. 5 in Bergk), which may or may not be genuine, —"rejecting the four toned song, we will sing to thee new hymns with the seven-voiced lyre,"—Strabo says that he increased the number of strings in the lyre from four to seven; others take the fragment to mean that he developed the citharœdic nomos (sung to the accompaniment of the cithara or lyre) by making the divisions of the ode seven instead of four. We possess six short fragments of poetry in the Dorian dialect bearing the name of Terpander. They are from hymns to the gods Zeus, Apollo, Apollo and the Muses, the Dioscuri, etc., and are written in a slow spondaic movement or in dactyls. They present no remarkable features and are probably spurious.

Bergk, *Poetæ Lyrici Græci*, iii. (4th ed.) pp. 7–12, Leipsic, 1882.

TERRACINA, a town of Italy, in the province of Rome, and about 60 miles to the southeast of that city, at the southeast extremity of the Pontine marshes, where the Monti Lepini (see ITALY, vol. xiii. p. 448, and LATIUM) descend into the sea. The ancient town (Volscian *Anxur*, Roman *Tarracina*) stood on the white hillside ("impositum saxis late candentibus Anxur"), along the foot of which, by the seashore, ran the Via Appia. The modern town stands mainly on the level ground. The most conspicuous building is the cathedral, which is believed to occupy the site of a temple of Jupiter Anxurus; it is enriched both externally and internally with beautiful old columns and Roman mosaics. Above the town, on the summit of the cliff, are the remains of a palace of Theodoric (c. 500), afterwards a mediæval castle. The ancient harbor, constructed by Antoninus Pius and once very important is now silted up; a new mole affords shelter to coasting vessels. Fishing is carried on, and there is some trade in the produce of the district. The population of the town in 1881 was 6294 (commune, 8572).

Anxur finally became Roman in 400 B.C., and a colony was established there in 329. Its strategic position early gave it military importance; and its pleasant situation and its mineral waters led many Romans to build villas and seek seaside quarters there.

Meaning.

TERRA-COTTA.[1] Strictly speaking this name is applicable to all objects made of baked clay, from the rudest brick to the finest piece of pottery, but it usually has a more limited meaning, to denote fictile objects which do not come under the head of pottery, such as statuettes and busts; and in its architectural use it specially implies the finer sorts of decorative clay-work, to the exclusion of common building bricks. In ancient times, especially among the Greeks and Romans, terra-cotta was employed for an immense variety of purposes, from the commonest objects of everyday use to the most elaborate and ambitious works of art, such as colossal statues and groups. Though the natural color and surface of the burnt clay are generally very pleasing in tone and texture, it seems to have been universally the custom in classical times to cover the terra-cotta completely with a thin white coating, which formed an absorbent ground for the further application of color. For internal work, except in rare instances, these colors were mixed with a tempera medium, and applied after the clay had been fired. They were therefore not true ceramic colors; and pigments of great variety and brilliance could be employed, as they had not to undergo the severe ordeal of the kiln. For external work, such as that shown in Fig. 5, only earth pigments such as ochres and lime were used, and the colors were fired.

Greek figures and reliefs.

No branch of archæology has during the last dozen years or so developed so rapidly as that of Greek terra-cotta figures; on this most fascinating subject an astonishingly large mass of literature has been published in Germany and France.[2] The discovery of this new world of Greek art began practically in 1873, with the first excavations in the tombs of Tanagra, a Bœotian town on the high road from Athens to the north, which brought to light a number of very beautiful terra-cotta statuettes.[3] Subsequent excavations at Corinth, Smyrna, Cyme, Tarentum, the Cyrenaica, and many other places also yielded a vast number of terra-cotta figures of various dates and styles. By far the greater number belong to the second half of the 4th century B.C.; but examples of an earlier date are not wanting, not only of figures in the round, but also of reliefs, which appear to have been largely used for the decoration of the flat surfaces of walls and friezes. The earliest of all date from a quite prehistoric period, and are mostly small idol-like figures of the rudest possible form, having an almost shapeless trunk with stick-like projections for the limbs, and the breasts and eyes roughly indicated by round dots. They are usually decorated with coarse stripes or checks in ochre colors. Examples of these have been found at Hissarlik (Troad), in Cyprus and other islands, and in the citadel of Tiryns in 1884–85 by Dr. Schliemann and Dr. Dörpfeld. Later but still very archaic figures, 2 or 3 inches high, have been exhumed in many parts of the Ægean Islands; some of these are stiff seated figures of deities,—links between Oriental and Hellenic art, like the statues of the Sacred Way at Branchidæ (south of Miletus). Comparatively few specimens

Early terra-cottas.

---

[1] An Italian word meaning literally "baked earth."

[2] See list at the end of the present article.

[3] See *Bull. Com. Inst. Arch.*, 1874, p. 120. Many thousand tombs have been opened at Tanagra, partly cut in the rock and partly built of masonry. The statuettes were either arranged round the body or packed in large vases. The costume of the female figures is the same as that described by classical writers as being peculiar to the neighboring city of Thebes. The finest of the Tanagra figures are from 8 to 9 inches high.

exist of the best period of Greek art—the 5th century.[1] A relief in the Louvre (about 18 by 12 inches) with a pierced background, dating from the first half of the 5th century, represents two female mourners at a sepulchral stele,—one standing and the other seated; under the foot of the latter is inscribed ΑΛΕΚΤΡ. On the other side of the stele are two youths (the Dioscuri) standing by a horse. The whole design is simple, but very graceful, and the modelling is skilfully treated in very low relief. The coloring—blue, red, white, and dark brown—is well preserved. This relief was pressed in a mould, and was intended to be attached to a wall, probably that of a tomb, as a votive offering to the dead.[2]

Tanagra statuettes.

In most cases the terra-cotta figures and reliefs occur in or close by tombs, but it is only in comparatively rare instances that the subjects represented have any reference to death. Another large class have been found in the vicinity of temples, and are probably votive offerings, such as the small statuettes of horses from the acropolis of Athens, now in the Louvre. In other cases, as at Halicarnassus, great quantities of small figures were buried under a temple, probably to purify the site, as was done in Egypt under the later dynasties, when many hundred figures of bronze were sometimes buried under one building. Owing to the fact that the statuettes found scattered in and round tombs have frequently their heads broken off, Pottier and Reinach have suggested that they were brought as offerings to the dead and their heads were broken off by the mourners at the side of the tomb. Rayet believes that this practice was a sort of survival of the custom of sacrificing female and boy slaves at the tombs of the dead. In many cases, however, the figures are intact, and it is probable that many of the tombs were broken open and rifled long ago, which would explain the mutilated and scattered condition of the figures. The tombs of Tanagra have yielded by far the richest finds of these figures, the specimens being very remarkable for their beauty. These exquisite statuettes do not (in most cases) represent deities or heroic personages, but the homely everyday life of the Greeks, treated with great simplicity and evident realism: they are in plastic art what in painting would be called *genre*,[3] and in their strong human interest and naturalistic pathos bring us in closer contact with the life and personalities of the past than any more ambitious style of art could possibly do. Moreover, they prove more clearly even than the great plastic works in bronze and marble how deeply a feeling for beauty and a knowledge of art must have penetrated the whole mass of the people. Their immense number shows that they must have been far from costly, within the reach of every one, and certainly not the production of any famous sculptors. Nevertheless, sketchy as they are in treatment and often faulty in detail, they are in pose, in motive, and in general effect works of the highest beauty, full of the most inimitable grace, and evidently the production of men in whom the best qualities of the sculptor were innate by a sort of natural birthright. Several small figures from Myrina (Mysia) have the artist's name inscribed on them; but signatures of this sort are rare.[4]

Subjects and designs.

It is impossible to describe the many subjects treated. Only a few examples can be mentioned. Among single figures the most frequent are those of girls standing or seated in an immense variety of pose, and with plentiful drapery arranged in countless methods, showing the great taste with which a Greek lady could dispose the folds of her ample pallium, whether it hung in graceful loops or was wound closely round the figure or formed a hood-like veil over the head. In some the lady holds a leaf-shaped fan, or is looking in a circular mirror, or holds a ball ready for the game. Many have a strange broad hat, probably of straw, which does not fit on the head, but must have been fastened by a pin to the hair or veil. One very beautiful motive is that of a girl playing with an infant Eros, who flies to her for shelter, and is received with welcome half tinged with dread. Fig. 1 shows a very lovely statuette of this kind, now in the Hermitage Palace. A favorite subject is taken from a game in which one girl carries her playmate on her back,—a motive which, though difficult to treat in sculpture, is managed very gracefully in terra-cotta. Other very lovely groups are Aphro-

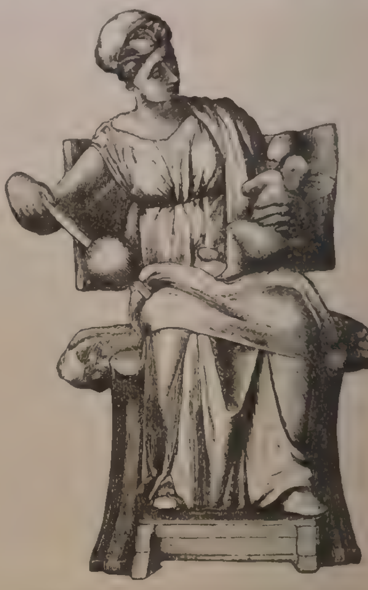

FIG. 1.—Statuette of a girl and infant Eros from Tanagra. (St. Petersburg.)

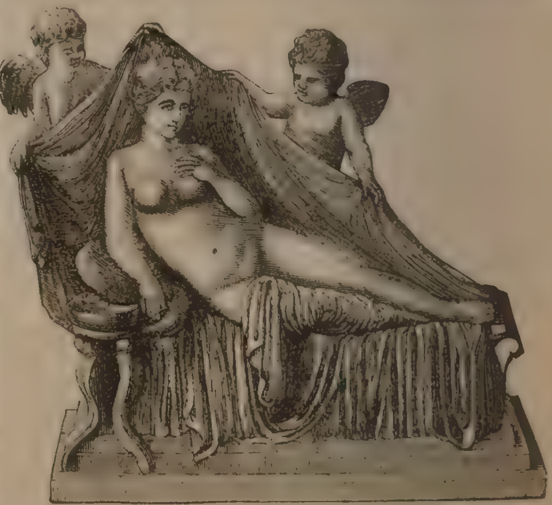

FIG. 2.—Aphrodite and cupids. The pendant hung round the neck of Aphrodite is gilt. (South Kensington Museum.)

---

[1] A good example of a terra-cotta relief of the first part of the 5th century B.C. is figured in vol. ii. p. 308.

[2] Some very beautiful fragments of reliefs in terra-cotta are preserved in the museums of the Louvre, of Copenhagen, and the Kircheriano in Rome. These represent on a small scale parts of Phidias's Panathenaic frieze, which have all the appearance of being works of the 5th century B.C., but may possibly be forgeries or Roman copies; see Waldstein, *Art of Pheidias*, Cambridge, 1885.

[3] In some the most homely sort of *genre* is represented,—a girl milking a cow, a cook or a barber at his work, etc. Even portrait figures occur, as, for example, a wonderfully lifelike group of a man and his wife in the collection of Mr. Ionides, recently lent to the South Kensington Museum.

[4] See *Gaz. des B.-Arts*, xxxiii., 1886, p. 278.

dite suckling the baby Eros, or with more than one cupid hovering round her. A very beautiful example (see Fig. 2) occurs in the South Kensington Museum (from the Castellani sale). It represents a half-nude figure of Aphrodite reclining on a couch, with two cupids behind holding up a veil, which was colored blue to form a background to the creamy white of Aphrodite's body.

Technical methods.

The Tanagra and other figures are all formed of thin pieces of soft clay pressed into a mould, usually formed in two halves and then stuck together; and they are made hollow so as not to warp and crack in the firing, and have a hole at the back for the escape of moisture during that process. The head is solid and was formed in a separate mould, as were also any accessories, such as fans or mirrors, and arms if they extend away from the body. Replicas of the same figure are often varied by having different heads or accessories; three or four examples have been found from the same mould. After the whole was put together it was usually touched up and finished with modelling tools. The color was applied after baking; a coating of creamy white lime or chalk all over served as the flesh tint and also as a good ground for the other colors. The hair of the females is always of a rich auburn red, such as the Venetians were so fond of painting in the 16th century; blue was touched on the eyes and crimson on the lips. Drapery, if not white, was usually rose-color or blue, often with a fringe or bands of gold on the border. Necklaces, earrings, and other ornaments were generally gilt, the gold leaf being applied over a slightly raised surface of slip, as on the Greek vases. Similar examples have been found in tombs at Thebes, at Thespiæ, and round Athens. Some of the Attica figures are covered, not with the usual non-ceramic colors, but with a real white enamel, the vitrified surface of which is very often slightly decomposed; further colored decoration was in some cases added over this enamel.

Asia Minor statuettes.

A number of places in the west of Asia Minor have yielded large quantities of terra-cotta figures, very similar in size and technique to those of Tanagra, but belonging for the most part to quite a different school of sculpture. Unlike the Tanagra figures, which are rather pictorial in style and deal with *genre* subjects, those from Smyrna, Cyme, Myrina, and other places in Asia Minor are thoroughly sculpturesque in design, and are frequently miniature reproductions of large statues or groups (see Fig. 3). Many of them stand on moulded pedestals, while the Tanagra figures have only a thin slab of clay as a base. The average size of both classes is from 6 to 10 inches high. Very elaborate groups with three or four figures often occur. Dionysiac and Bacchanal subjects are frequently chosen, or scenes from sacred mythology, such as the labors of Heracles.[1] These also mostly date from the 4th century B.C., and the statuettes often appear to be copies from sculpture of the school of Praxiteles or Scopas. One instance is the fine nude figure of Eros as a youth leaning against a cippus, holding a bronze arrow in his hand, in the collection of M. de Branteghem, now in Rome.[2] The whole of it was gilt, which was frequently the case with the Asia Minor statuettes, but rarely so in those of Tanagra.[3] A very beautiful figure of a winged Victory in the same collection (from the Castellani sale) presents the same motive as the colossal Victory of Samothrace (in the Louvre); it supplies the missing right hand, which in the terra-cotta contains a bunch of roses. The drapery of this figure is blue, mottled, or shot with gold. Other figures, from their heights being arranged in even gradations, seem to be copies from some large pedimental sculpture. Unfortunately little is yet known of the various fabriques of these Asia Minor figures, as in most cases their *provenance* is very doubtful.[4] The Lecuyer collection possessed some groups with several figures forming important compositions. One of these shows two female mourners at a tomb, and a warrior clad in full armor with his horse. The most remarkable group (see Fig. 4) is that of a soul led by Hermes Psychopompus to the bark of Charon, who is represented as a bent aged man. Hermes, a graceful nude figure, gently urges the shrinking soul—a draped female figure—to the boat at the brink of the rush-grown Styx. The whole scene is imagined with much tender grace and real pathos, though not highly finished in its details. One of the most important terra-cotta figures yet discovered has recently been brought to England from Smyrna. It is a very beautiful copy of the Diadumenos of Polycletus, which in the details of its modelling reproduces some characteristics of the later school of Praxiteles. The forearms and the legs below the knee are lost; but in breadth of modelling and grandeur of style this little figure, which was only about 14 inches high when perfect, has the effect of a much larger statue, and it is a real masterpiece of Greek plastic art.[5] In the neighborhood of Smyrna and Ephesus a large number of caricature figures have been exhumed, some of which are modelled with a wonderful feeling for humor.[6] These strange figures have attenuated limbs, large heads, flapping ears, and goggle eyes. Some play on musical instruments; others represent actors; and one in the De Branteghem collection is a caricature of a discobolus in almost the attitude of Myron's celebrated statue.

---

[1] Fine examples of all these existed in the collection of M. Lecuyer, which is now dispersed (see Lenormant, *Coll. Lecuyer de terre-cuites*, Paris, 1884, which is well illustrated with photographs).

[2] In a few other examples objects of bronze are placed in the hands of the figures.

[3] The lovely series of little figures of dancing cupids from Tanagra, some of which are in the Louvre and others in the South Kensington Museum, were wholly gilt, but the larger statuettes of Tanagra appear to have had gold applied only for special ornaments.

[4] For many reasons both finders and dealers usually wish to keep secret where valuable finds are made. In most museums the labels simply repeat the dealer's account (for want of better information), so that the statement of the *provenance* must usually be accepted with caution.

[5] See *Journ. of Hellenic Studies*, vol. vi., 1886, p. 243.

[6] The British Museum possesses some fine caricatures of actors from Canino, very skilfully modelled and of a peculiar fabrique.

Cyrenaic statuettes.

A very different class of statuettes has recently come to light in the Cyrenaica, on the northern coast of Africa. Many of these are nude female dancers wearing an elaborate stephanos-like head-dress. They are realistic in modelling and very ungraceful in pose,—a striking contrast to the exquisite taste of the Tanagra and most of the Asia Minor figures. Recent excavations in the tombs of Corinth have produced a large number of fine terra-cottas, ranging in date over a very long period.

Tarentine busts.

Another and artistically very perfect class of figures is being dug up from among the tombs of Tarentum. Some of these belong to the finest period of Greek art, probably about 400 B.C., and others are even earlier. Many are not statuettes, but merely small busts of heroic style, and of the highest sculpturesque beauty. They are certainly not portraits, and do not appear to represent deities. It has been suggested that they are idealized representations of ancestors whose commemoration, in some places, formed an important cult; but their real meaning must for the present remain uncertain. Many thousand votive figures and reliefs in clay have been found within the *temeni* of the temples of the Chthonian deities at Tarentum and elsewhere. It seems to have been customary for the priests periodically to clear out of the temples the broken or too numerous offerings which were then buried within the enclosure; whole series arranged chronologically in groups have been discovered buried in separate holes.

Terra-cotta jewelry.

In addition to statuettes and reliefs, terra-cotta was used by the Greeks for various minor ornamental purposes. Delicately moulded necklaces and pendants for ears were stamped out in clay and then thickly covered with gold leaf; this produced a very rich effect at a small cost; many fine examples are preserved in the Louvre. Children's toys, such as miniature horses and chariots, and dolls with movable limbs of terra-cotta fastened with wooden pegs, occur in many tombs.

Use in Greek architecture.

On a larger scale terra-cotta was adapted by the Greeks to important architectural ornamentation. Many fine examples have been found at Olympia and among the ruined temples of Selinus. In some cases the main cornices of the building were simply blocked out square in stone, and then covered with moulded plaques of terra-cotta, carefully formed to fit on and round the angles of the block. The large cymatium which forms the upper member of the cornice is curved upwards, so as to prevent the rain water from dripping all along the edge; and at intervals it is pierced by ornamental clay pipes, which project like a mediæval gargoyle. In some examples from Selinus the cymatium is pierced with a beautiful open pattern of lotus leaf (see Fig. 5). The greatest care was taken in fitting these applied mouldings where each plaque joined the next, and especially in making them fit closely on to the stone blocks, in which rebates were cut to receive each plaque. The whole surface of the terra-cotta is covered with elaborate painted ornaments of great beauty, in ochre colors applied on a white ground, as in the case of the statuettes. These beautiful temple decorations are well illustrated by Dörpfeld and others in *Die Verwendung von Terra-cotten*, Berlin, 1881. Though no complete examples of terra-cotta statuary now exist, it is certain that the Greeks produced it on a large scale and of the highest class of workmanship. Pliny (*H. N.*, xxxv. 36) mentions that certain statues of Hercules Musagetes and the Nine Muses were "opera figlina," executed by the painter Zeuxis. These were brought from Athens[1] by M. Fulvius Nobilior, and placed in the temple of Hercules Musagetes, which adjoined the Porticus Octaviæ in the Campus Martius of Rome. Other and earlier examples of clay statues are mentioned by Pausanias.

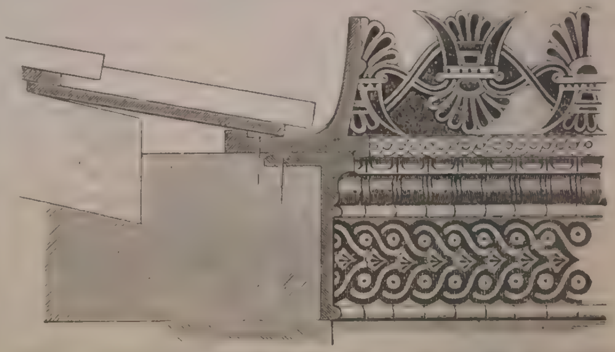

FIG. 5.—Cornice enrichments of painted terra-cotta from Selinus. This section shows the careful way in which the terra-cotta is fitted on to the stone; the colors are red and brown ochre and cream-white.

Etruscan.

Among the Etruscans the use of clay for important sculpture was very frequent,—painted terra-cotta or bronze almost excluding marble and stone. An important example was the clay quadriga on the pediment of the temple of Capitoline Jupiter, which, according to one legend, was brought from Veii by Tarquinius Superbus. This existed till the destruction of the temple by fire in 83 B.C., and was considered one of the seven precious relics on which the safety of the Roman state depended. The great statue of Jupiter in the central cella of this triple temple was also of terra-cotta, and was said to be the work of an Etruscan sculptor from Fregenæ. Vitruvius mentions "signa fictilia" as being specially Etruscan. Many other statues in the early temples of Rome were made of the same material. Among the existing specimens of Etruscan terra-cotta, the chief are large sarcophagi, with recumbent portrait effigies of the deceased on the top, the whole being of clay, decorated with painting. Fine examples exist in the Louvre and the British Museum; a good specimen from the latter collection is figured in vol. viii., plate VIII. The Museo Gregoriano in the Vatican possesses some very beautiful friezes of a later date—about the 4th century B.C.—when native Etruscan art had been replaced by that of Greece. These friezes are very rich and elaborate, with heads and scroll foliage in very salient relief. Some of them have at intervals cleverly moulded heads of satyrs, painted a brilliant crimson.[2]

Magna-Græcian.

Another very elaborate application of terra-cotta is shown in the numerous large asci, covered with statuettes, which are found in the tombs of Canosa (Canusium), Cales, and many parts of Magna Græcia. The statuettes are somewhat similar in style and coloring to the Tanagra figures, and date from about the same period (4th century B.C.), but are not equal to them as works of art; they are also usually crowded together in a somewhat awkward manner.[3] The British Museum is specially rich in these elaborate terra-cottas; few of the colors used appear to be true ceramic pigments.

[1] [Pliny says *loco cit.* "from Ambracia." See also vol. i. p. 582. —AM. ED.]

[2] The use of this strongly glowing red is almost peculiar to Hellenic Italy; the other colors used there were much the same as those of Greece itself. The same magnificent crimson often occurs on œnochoæ, moulded into the form of satyrs' heads, which are found in the tombs of Magna Græcia.

[3] A very large ascus from Canosa in the British Museum is decorated with no less than five statuettes of women and Victories, two large masks of Medusa, and six projecting figures of horses.

Roman.

As in other branches of art, the Romans closely copied the Greeks in their wide application of terra-cotta for statues, reliefs, and architectural ornaments. A large number of beautiful Græco-Roman reliefs exist, many having designs evidently copied from earlier Greek sculpture. Berlin, the Louvre, the British Museum, and many places in Italy possess fine collections. Friezes with beautiful reliefs 12 to 18 inches deep often occur, little inferior in execution to the earlier Greek work. Many subjects of great interest are represented; a very fine plaque in the Louvre has the scene of Orestes taking refuge at the sacred omphalos at Delphi, which is represented as a conical stone about 3 feet high, hung round with ornamental festoons made of gold.[1] These terra-cottas belong to the early period of the empire: in the second century A.D. they became much coarser and less Greek in style, like all the sculpture of that time. A plaque in the Louvre, which represents a chariot-race in the circus, bears its maker's stamp **L.S.ER.** At the end of the first and in the early part of the 2d century A.D. the use of terra-cotta for architectural adornment was carried to a high point of perfection in Rome. Many buildings of this period have the most elaborate decoration moulded in clay and fitted together with wonderful neatness. Not only enriched cornices and friezes were made of terra-cotta, but even Corinthian columns with their elaborate acanthus capitals. In all cases the whole surface appears to have been covered with a thin coating of "opus albarium" and then decorated with colors and even gold. The best existing examples in Rome are the Amphitheatrum Castrense, many tombs on the Via Latina, and the barracks of the VIIth cohort of the guards (*vigiles*) in the Trastevere. But few examples exist of the large Roman terra-cotta sculpture; the best are some seated female figures from tombs, small life-size, in the Capitoline museum,—works of great beauty and very skilfully fired without cracks or warping. The British Museum also contains fine specimens of terra-cotta sculpture on a large scale, especially the torso of a nude male figure (Hercules), some terminal figures of Bacchus, and a beautiful statue of Urania (see Fig. 6).

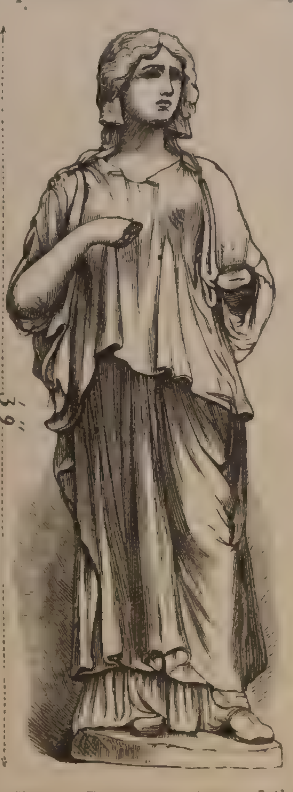

FIG. 6.—Terra-cotta statue of the Muse Urania, 1st century A.D. (British Museum.)

Mediæval.

In the 14th and more especially in the 15th century terra-cotta was adapted in various parts of Europe to the most magnificent and elaborate architectural purposes. In Germany the mark of Brandenburg is especially rich in terra-cotta work.[2] The church of St. Catherine in the town of Brandenburg is decorated in the most lavish way with delicate tracery and elaborate string-courses and cornices, enriched with foliage all modelled in clay; the town-hall is another instance of the same use of terra-cotta. At Tangermünde, the church of St. Stephen and other buildings of the beginning of the 15th century are wonderful examples of this method of decoration; the north door of St. Stephen's especially is a masterpiece of rich and effective moulding. In northern Italy this use of terra-cotta was carried to an equally high point of perfection.[3]

Italy.

The western façade of the cathedral of Monza is a work of the most wonderful richness and minute elaboration, wholly executed in clay, in the latter part of the 14th century. The cathedral of Crema, the communal buildings of Piacenza, and S. Maria delle Grazie in Milan are striking examples of the extreme splendor of effect that can be obtained by terra-cotta work. The Certosa near Pavia has a most gorgeous specimen of the early part of the 16th century; the two cloisters are especially magnificent. Pavia itself is very rich in terra-cotta decoration, especially the ducal palace and the churches of S. Francesco and S. Maria del Carmine. Some delicate work exists among the mediæval buildings of Rome, dating from the 14th and 16th century, as, for example, the rich cornices on the south aisle of S. Maria in Ara Cœli, *c.* 1300; the front of S. Cosimato in Trastevere, built *c.* 1490; and a once very magnificent house, near the Via di Tordinone, which dates from the 14th century. The most important application of terra-cotta in mediæval Italy was to statuary—reliefs, busts, and even groups of many life-sized figures—during the 15th and 16th centuries. Much of the Florentine terra-cotta sculpture of the 15th century is among the most beautiful plastic work the world has ever seen especially that by Jacopo della Quercia, Donatello, and the sculptors of the next generation.[4] For life, spirit, and realistic truth combined with sculpturesque breadth, these pieces are masterpieces of invention and manipulation. The portrait busts are perfect models of iconic sculpture (see Fig. 7). In some respects the use of burnt clay for sculpture has great advantages over that of marble; the soft clay is easily and rapidly moulded into form while the sculptor's thought is fresh in his mind, and thus terra-cottas often possess a spirit and vigor which can hardly be reproduced in the laboriously finished marble. These qualities are specially remarkable in the best works of

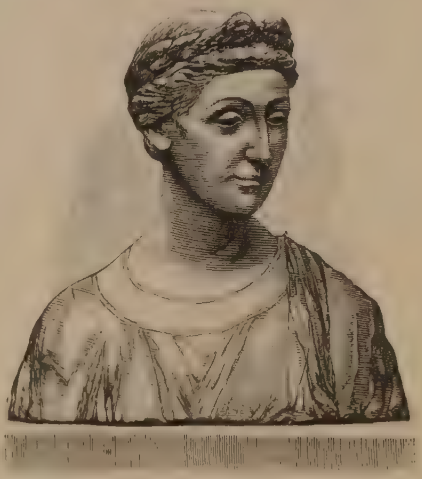

FIG. 7.—Portrait bust in terra-cotta: Florentine work of the middle of the 15th century. (South Kensington Museum.)

[1] Compare a similar representation of the omphalos on a Greek vase illustrated by Jahn, *Vasenbilder*, Hamburg, 1839.

[2] See Adler, *Mittelalterliche Backstein-Bauwerke*, Berlin, 1862.

[3] See Gruner, *Terra-cotta Architecture of N. Italy*, London, 1867.

[4] The South Kensington Museum possesses a very fine collection of Florentine terra-cottas of the best period.

the Della Robbia family, (see ROBBIA). In the 16th century a more realistic style was introduced, and this was heightened by the custom of painting the figures in oil colors. Many very clever groups of this class were produced by Ambrogio Foppa (Caradosso) for S. Satiro at Milan and by Guido Mazzoni and Begarelli (1479–1565) for churches in Modena. These terra-cotta sculptures are unpleasing in color and far too pictorial in style; but those of Begarelli were enthusiastically admired by Michelangelo.[1]

France.

Much fine terra-cotta work was produced in France during the 16th century, partly under Italian influence,—many sculptors from northern and central Italy having settled in France, especially under the patronage of Francis I. In the same century a similar Italian influence prevailed largely throughout Spain, and very clever works were produced there, remarkable for their vivid realism and deceptive pictorial style.

England.

In England the elaborate use of terra-cotta did not come into vogue till the early part of the 16th century, and then only in certain counties. Essex possesses the finest examples, such as those of the manor house of Layer Marney, built in the reign of Henry VIII. The richly moulded windows and battlements of this house are very un-English in style and it seems probable that all the terra-cotta decorations were made in Holland or Flanders. A richly decorated terra-cotta tomb, with recumbent effigy exists in the church of Layer Marney; and in the collegiate church of Wymondham in Norfolk there are very large and elaborte sedilia with lofty canopied, niches all of clay, which appear to be of the same date and fabrique as the Essex examples. Most of the terra-cotta sculpture in England, such as that by Torrigiano, of which fragments exist in Westminster Abbey, the colossal heads of the Cæsars at Hampton Court, and the recumbent effigy in the Chapel of the Rolls,[2] were the work of Italian sculptors, mostly from Florence, who were invited to England in the reigns of Henry VII. and Henry VIII.

Modern.

Of late years terra-cotta for architectural purposes has been employed for some very important buildings in London, such as the natural history museum at South Kensington, the Albert Hall, and the front of the other museum in the Exhibition Road. The durability of well-fired clay, its dense texture, pleasant color, and smooth surface make it specially suitable to an atmosphere laden with acids and soot as is that of London. The surface resists decomposition, and affords little hold to the minute particles of carbon. The great improvements which have been made in the manufacture of terra-cotta will probably lead to its more extensive use. The great difficulty is to retain the sharpness of impression given by the mould, and above all to avoid the uneven shrinkage and warping which is so liable to take place when it is fired in large pieces. Any want of truth in the lines of a long cornice becomes painfully apparent, and each moulded block of a door or window-jamb must fit accurately on to the next one, or else the line of moulding becomes broken and irregular. Terra-cotta is now made of many different colors, a rich red and a warm ochre or cream color being the most pleasant to the eye. In order to avoid defects it is necessary that the clay should contain a large proportion of powdered silica, and that the whole mass should be thoroughly homogeneous. The method by which these ends are secured is much the same as that employed in the making of pottery (see vol. xix. p. 663 *sq.*).

Collections.

The most important public collections are in the Louvre, the British Museum, the museums of Berlin and Athens, and a few fine specimens exist in the South Kensington Museum. The splendid Sabouroff collection is now in the Hermitage Palace at St. Petersburg. Many museums in Italy—such as those at Florence, Perugia, Capua, Rome, and other places—contain many examples from Etruria and Magna Græcia. A large number of the finest of the Tanagra figures and the like are in private hands; some are illustrated in the works mentioned in the following list; that of Prince Liechtenstein at Vienna is one of the finest.[3]

Literature.—Léon Heuzey, "Recherches sur les figurines de femmes voilées," in *Mon. assoc. des études grecques*, Paris, 1874; Id., "Rech. sur un groupe de Praxitèle, . . . en terre cuite," in *Gaz. des B.-Arts*, September, 1875; Id., "Rech. sur les terres cuites grecques," in *Mon. assoc. des étud. grec.*, 1876; Id., *Les origines des terres cuites*, Paris, 1882; Id., *Catalogue des figurines antiques du Louvre*, Paris, 1882–83; Id. Papposilène et le dieu Bes," in *Bull. Cor. Hell.*, 1884, p. 161-167; Fröhner, *Les terres cuites d'Asie-Mineure*, Paris, 1879-81; Id., *Cat. de la Coll. Lecuyer*, Paris, 1883, and *Cat. de la Coll. Barre*, Paris, 1878; Kekulé, *Griechische Thonfiguren aus Tanagra*, Berlin, 1878; Id., *Griechische Terracotten vom Berliner Museum*, Berlin, 1878; Id., *Die antiken Terracotten von Pompeii*, Stuttgart, 1880; Rayet, *Monuments de l'art antique*, Paris, 1884, vol. ii. pp. 74-90; Id., "Sur une plaque estampée," in *Bull. Cor. Hell.*, 1879, pp. 329-333; Id., *Cat. de la Coll. Rayet*, 1880; Id., "Les figurines de Tanagra (Louvre)," in *Gas. des B.-Arts*, 1875; Id., "L'art grec au Trocadéro," in *Gaz. des B.-Arts*, 1878; Furtwaengler, *La Coll. Sabouroff*, Paris, 1882-85, splendidly illustrated in colors; Martha, *Cat. des figurines du musée d'Athènes*, 1880; Id., "Figurines corinthiennes en terre cuite," in *Bull. Cor. Hell.*, 1879, pp. 29-42; Id., "Figurines de Tanagra," *ibid.*, 1880, pp. 71-75; Pottier, "Terres cuites Chypriotes," *ibid.*, 1879, pp. 86-94; Pottier and Reinach, "Fouilles de Myrina," *ibid.*, various articles in vols. for 1882–83; Paul Girard, "Nécropoles de la Grèce du Nord," *ibid.*, 1879, pp. 211-221; Max. Collignon, "Plaque estampée de Santorin," *ibid.*, 1881 pp. 436-438; Cesnola, *Cyprus*, London, 1877; Schliemann, *Troy, Mycenæ*, and *Tiryns;* E. Curtius, *Giebelgruppen aus Tanagra*, Berlin, 1878; Delauney, "Terres cuites de Tanagra," in *Revue de France*, May and June, 1878. An account of the first discovery of the Tanagra figures is given by Otto Lüders in *Bull. Inst. Cor. Arch.*, 1874, p. 120; see also various articles in *Gaz. Archéol.*, *Archäol. Zeitung*, and *Mon. Inst. Arch. Rom.* (especially vol. vi.). For the earlier known terra-cottas, see Panofka, *Terracotten des k. Museums zu Berlin*, 1842; Combe, *Terra-cottas in the British Museum*, London, 1810; and Gerhard, *Monumenti figulini di Sicilia*, Berlin, 1835. Other works have been already referred to. Clever but not quite satisfactory copies of the finest Tanagra and other figures are now made in Berlin and Vienna; they cost from twenty to thirty shillings each. (J. H. M.)

TERRANOVA, or **TERRANUOVA**, a seaport town of Sicily, on a hill at the mouth of the Terranova, in the province of Caltanisetta, and 41½ miles east-south-east from Girgenti. It contains a castle and several large churches, but has little to interest the traveller. Though the harbor is poor, there is a considerable trade in corn, wine, fruit, sulphur, and soda. Cloth is manufactured to a small extent. The population of the town in 1881 was 16,440, that of the commune 17,173. In and near Terranova are the remains of the ancient GELA (*q.v.*). The modern town owes its origin to the emperor Frederick II.

TERRAPIN, see TORTOISE.

TERRE HAUTE, a city of the United States, in Harrison township, Vigo county (of which it is the county seat), in the western part of Indiana. It is situated in 39° 27′ N. lat. and 87° 54′ W. long., at a height of 492 feet above the sea, upon the east bank of the Wabash river, 186 miles nearly south of Chicago and 73 miles west-southwest of Indianapolis. The city stands upon level ground, about 60 feet above the ordinary surface of the river. It is regularly laid out, with wide streets, lined with shade trees; its principal buildings are the State normal school and the Polytechnic Institute. Six great railroad lines pass through Terre Haute, connecting it directly with the cities of the Mississippi valley. This fact, together with its proximity to the coal-mines of Clay county, has greatly promoted its growth as a manufacturing centre. It had in 1880 a population of 26,042, as against 16,103 in 1870.

TERSTEEGEN, GERHARD (1697–1769), German religious writer, was born at Mörs in Rhenish Prussia on 25th November, 1697. After being educated at the gymnasium of his native town, he pursued for some years the calling of a ribbon-maker. In 1728 he withdrew from all secular pursuits and gave himself entirely to religious work. His writings include a collection of hymns (*Blumengärtlein*, 1729; last edition, Stuttgart, 1868), a volume of *Gebete*, and another of *Briefe*. He died at Mühlheim in Rhenish Prussia on 3d April, 1769. See HYMNS, vol. xii. p. 622.

---

[1] See Vasari, ed. Le Monnier, xii. 281.

[2] This interesting building is now threatened with destruction.

[3] Very clever forgeries of terra-cotta are being manufactured, and in many cases real specimens have genuine heads which do not belong to them. The coloring has frequently been touched up and falsified while in the dealers' hands. Even the celebrated Campana collection contained many clever forgeries of terra-cotta reliefs.

TERTIARIES. See FRANCISCANS. vol. ix. p. 616.

TERTULLIAN, whose full name was QUINTUS SEPTIMIUS FLORENS TERTULLIANUS, is the earliest and after Augustine the greatest of the ancient church writers of the West. Before him the whole Christian literature in the Latin language consisted of a translation of the Bible, the *Octavius* of Minucius Felix—an apologetic treatise written in the Ciceronian style for the higher circles of society, and with no evident effect for the church as a whole—and a list of the books recognized as canonical (the so-called Muratorian fragment). Whether Victor the Roman bishop and Appollonius the Roman senator ever really made an appearance as Latin authors is quite uncertain. Tertullian in fact created Christian Latin literature; one might almost say that that literature sprang from him full-grown, alike in form and substance, as Athene from the head of Zeus. Cyprian polished the language that Tertullian had made, sifted the thoughts he had given out, rounded them off, and turned them into current coin, but he never ceased to be aware of his dependence on Tertullian, whom he designated as *κατ' ἐξοχήν* his master (Jer., *De Vir. Ill.*, 53). Augustine, again, stood on the shoulders of Tertullian and Cyprian; and these three North Africans are the fathers of the Western churches.

Tertullian's place in universal history is determined by (1) his intellectual and spiritual endowments, (2) his moral force and evangelical fervor, (3) the course of his personal development, (4) the circumstances of the time in the midst of which he worked.

(1) Tertullian was a man of great originality and genius, characterized by the deepest pathos, the liveliest fancy, and the most penetrating keenness, and was endowed with ability to appropriate and make use of all the methods of observation and speculation, and with the readiest wit. His writings in tone and character are always alike "rich in thought and destitute of form, passionate and hair-splitting, eloquent and pithy in expression, energetic and condensed to the point of obscurity." His style has been characterized with justice as dark and resplendent like ebony. His eloquence was of the vehement order; but it wins hearers and readers by the strength of its passion, the energy of its truth, the pregnancy and elegance of its expression, just as much as it repels them by its heat without light, its sophistical argumentations, and its elaborate hair-splittings. Though he is wanting in moderation and in luminous warmth, his tones are by no means always harsh; and as an author he ever aspired with longing after humility and love and patience, though his whole life was lived in the atmosphere of conflict. Tertullian both as a man and as a writer had much in common with the apostle Paul.

(2) In spite of all the contradictions in which he involved himself as a thinker and as a teacher, Tertullian was a compact ethical personality. What he was he was with his whole being. Once a Christian, he was determined to be so with all his soul, and to shake himself free of all half measures and compromises with the world. It is not difficult to lay one's finger upon very many obliquities, self-deceptions, and sophisms in Tertullian in matters of detail, for he struggled for years to reconcile things that were in themselves irreconcilable; yet in each case the perversities and sophisms were rather the outcome of peculiarly difficult circumstances in which he stood. It is easy to convict him of having failed to control the glowing passion that was in him. He is often outrageously unjust in the substance of what he says, and in manner harsh to cynicism, scornful to gruesomeness; but in no battle that he fought was he ever actuated by selfish interests. What he did was really done for the Gospel, as he understood it, with all the faculties of his soul. But he understood the Gospel as being primarily an assured hope and a holy law, as fear of the Judge who can cast into hell and as an inflexible rule of faith and of discipline. Of the glorious liberty of the children of God he had nothing but a mere presentiment; he looked for it only in the world beyond the grave, and under the power of the Gospel he counted as loss all the world could give. He well understood the meaning of Christ's saying that He came not into the world to bring peace, but a sword; in a period when a lax spirit of conformity to the world had seized the churches he maintained the "vigor evangelicus" not merely against the Gnostics but against opportunists and a worldly-wise clergy. Among all the fathers of the first three centuries Tertullian has given the most powerful expression to the terrible earnestness of the Gospel.

(3) The course of Tertullian's personal development fitted him in an altogether remarkable degree to be a teacher of the church. Born at Carthage of good family—his father was a "centurio consularis"—he received a first-rate education both in Latin and in Greek. He was able to speak and write Greek, and gives evidence of familiarity alike with its prose and with its poetry; and his excellent memory—though he himself complains about it—enabled him always to bring in at the right place an appropriate, often brilliant, quotation or some historical allusion. The old historians from Herodotus to Tacitus, were familiar to him, and the accuracy of his historical knowledge is astonishing. He studied with earnest zeal the Greek philosophers; Plato in particular, and the writings of the Stoics, he had fully at command, and his treatise *De Anima* shows that he himself was able to investigate and discuss philosophical problems. From the philosophers he had been led to the medical writers, whose treatises plainly had a place in his working library. But no portion of this rich store of miscellaneous knowledge has left its characteristic impress on his writings; this influence was reserved for his legal training. His father, whose military spirit reveals itself in the whole bearing of Tertullian, to whom Christianity was above everything a "militia" had intended him for the law. He studied in Carthage, probably also in Rome, where, according to Eusebius, he enjoyed the reputation of being one of the most eminent jurists. This statement derives confirmation from the *Digest*, where references are made to two works, *De Castrensi Peculio* and *Quæstionum Libri VIII.*, of a Roman jurist named Tertullian, who must have flourished about 180 A.D. In point of fact the quondam advocate never disappeared in the Christian presbyter. This was at once his strength and his weakness: his strength, for as a professional pleader he had learned how to deal with an adversary according to the rules of the art—to pull to pieces his theses, to reduce him *ad absurdum*, and to show the defects and contradictions of his statements,—and was specially qualified to expose the irregularities in the proceedings taken by the state against the Christians; but it was also his weakness, for it was responsible for his litigiousness, his often doubtful shifts and artifices, his sophisms and *argumentationes ad hominem*, his fallacies and surprises. At Rome in mature manhood Tertullian became a Christian, under what circumstances we do not know, and forthwith he bent himself with all his energy to the study of Scripture and of Christian literature. Not only was he master of the contents of the Bible: he also read carefully the works of Hermas, Justin, Tatian, Miltiades, Melito, Irenæus, Proculus, Clement, as well as many Gnostic treatises, the writings of Marcion in particular. In apologetics his principal master was Justin, and in theology proper and in the controversy with the Gnostics, Irenæus. As a thinker he was not original, and even as a theologian he has pro-

duced but few new schemes of doctrine, except his doctrine of sin. His special gift lay in the power to make what had been traditionally received impressive, to give to it its proper form, and to gain for it new currency. From Rome Tertullian visited Greece and perhaps also Asia Minor; at any rate we know that he had temporary relations with the churches there. He was consequently placed in a position in which he could check the doctrine and practice of the Roman Church. Thus equipped with knowledge and experience, he returned to Carthage and there laid the foundation of Latin Christian literature. At first, after his conversion, he wrote Greek, but by and by Latin almost exclusively. The elements of this Christian Latin language may be enumerated as follows: (i.) it had its origin, not in the literary language of Rome as developed by Cicero, but in the language of the people as we find it in Plautus and Terence; (ii.) it has an African complexion; (iii.) it is strongly influenced by Greek, particularly through the Latin translation of the Septuagint and of the New Testament, besides being sprinkled with a large number of Greek words derived from the Scriptures or from the Greek liturgies; (iv.) it bears the stamp of the Gnostic style and contains also some military expressions; (v.) it owes something to the original creative power of Tertullian. As for his theology, its leading factors were—(i.) the teachings of the apologists; (ii.) the philosophy of the Stoics; (iii.) the rule of faith, interpreted in an anti-Gnostic sense, as he had received it from the Church of Rome; (iv.) the Soteriological theology of Melito and Irenæus; (v.) the substance of the utterances of the Montanist prophets (in the closing decades of his life). This analysis does not disclose, nor indeed is it possible to discover, what was the determining element for Tertullian; in fact he was under the dominion of more than one ruling principle, and he felt himself bound by several mutually opposing authorities. It was his desire to unite the enthusiasm of primitive Christianity with intelligent thought, the original demands of the Gospel with every letter of the Scriptures and with the practice of the Roman Church, the sayings of the Paraclete with the authority of the bishops, the law of the churches with the freedom of the inspired, the rigid discipline of the Montanist with all the utterances of the New Testament and with the arrangements of a church seeking to set itself up within the world. At this task he toiled for years, involved in contradictions which it took all the finished skill of the jurist to conceal from him for a time. At last he felt compelled to break off from the church for which he had lived and fought; but the breach could not clear him from the contradictions in which he found himself entangled. Not only did the great chasm between the old Christianity, to which his soul clung, and the Christianity of the Scriptures as juristically and philosophically interpreted remain unbridged; he also clung fast, in spite of his separation from the Catholic church, to his position that the church possesses the true doctrine, that the bishops *per successionem* are the repositories of the grace of the teaching office, and so forth. The growing violence of his latest works is to be accounted for, not only by his burning indignation against the ever-advancing secularization of the Catholic church, but also by the incompatibility between the authorities which he recognized and yet was not able to reconcile. After having done battle with heathens, Jews, Marcionites, Gnostics, Monarchians, and the Catholics, he died an old man, carrying with him to the grave the last remains of primitive Christianity in the West, but at the same time in conflict with himself.

(4) What has just been said brings out very clearly how important in their bearing on Tertullian's development were the circumstances of the age in which he labored. His activity as a Christian falls between 190 and 220, a period of very great moment in the history of the Catholic church; for within it the struggle with Gnosticism was brought to a victorious close, the New Testament established a firm footing within the churches, the "apostolic" rules which thenceforward regulated all the affairs of the church were called into existence, and the ecclesiastical priesthood came to be developed. Within this period also falls that evangelical and legal reaction against the political and secular tendencies of the church which is known as Montanism. The same Tertullian who had fortified the Catholic church against Gnosticism was none the less anxious to protect it from becoming a political organization. Being unable to reconcile incompatibles, he broke with the church and became the most powerful representative of Montanism in the West.

Although Tertullian's extant works are both numerous and copious, our knowledge of his life is very vague. He cannot have been born much later than about 150. His activity as a jurist in Rome must fall within the period of Commodus; for there is no indication in his writings that he was in Rome in the time of Marcus Aurelius, and many passages seem to preclude the supposition. The date of his conversion to Christianity is quite uncertain; there is much in favor of the years between 190 and 195. How long he remained in Rome after becoming a Christian, whether he had attained any office in the church before leaving Rome, what was the date of his visit to Greece,—on these points also we remain in ignorance. It is certain that he was settled in Carthage in the second half of 197, the date of his writing his *Apologeticus* and (shortly afterwards) his two books *Ad Nationes;* we also know that he became a presbyter in Carthage and was married. His recognition of the Montanistic prophecy in Phrygia as a work of God took place in 202–203, at the time when a new persecution broke out. For the next five years it was his constant endeavor to secure the victory for Montanism within the church; but in this he became involved more and more deeply in controversy with the majority of the church in Carthage and especially with its clergy, which had the support of the clergy of Rome. As Jerome writes (*De Vir. Ill.*, 53): "Usque ad mediam ætatem presbyter fuit ecclesiæ Africanæ, invidia postea et contumeliis clericorum Romanæ ecclesiæ ad Montani dogma delapsus." On his breach with the Catholic church, probably in 207–208, he became the head of a small Montanist community in Carthage. In this position he continued to labor, to write, and to assail the lax Catholics and their clergy until at least the time of Bishop Calixtus in the reign of Elagabalus. The year of his death is uncertain. Jerome (*ut sup.*) says: "Fertur vixisse usque ad decrepitam ætatem." That he returned at last to the bosom of the Catholic church is a mere legend, the motive of which is obvious; his adherents after his death continued to maintain themselves as a small community in Carthage. Although he had left the church, his earlier writings continued to be extensively read; and in the 4th century his works, along with those of Cyprian, were the principal reading of Western Christians, until they were superseded by those of Jerome, Ambrose, Augustine, and Gregory. Jerome has included him in his catalogue of Christian "viri illustres," but only as a Catholic to whom reference should be made with caution.[1]

The works of Tertullian, on the chronology of which a great deal has been written, and which for the most part do not admit of being dated with perfect certainty, fall into three classes,—the apologetic, the polemical theological, and the ascetic. And in point of time also three periods can be readily distinguished, the years 202–203 and 207–208 constituting the divisions. Some of the things he wrote have unfortunately disappeared, in particular the *De Spectaculis, De Baptismo*, and *De Virginibus Velandis* in Greek; his works in Latin on the same subjects have survived.

I. *Works dating from before* 202–203.—To this class belong the *Apologeticus* (197) and the two books *Ad Nationes, De Spectaculis, De Idololatria, De Cultu Feminarum Libri II., De Testimonio Animæ* (written soon after the *Apologeticus*), *Ad Martyres* (perhaps the earliest of all), *De Baptismo Hæreticorum* (now lost), *De Baptismo, De Pœnitentia, De Oratione* (the last three written for catechumens), *De Patientia, Ad Uxorem Libri II., De Præscriptione Hæreticorum*, and *Adv. Marcionem* (in its first form). The *Apologeticus*, which in the 3d century was translated into Greek, is the weightiest work in defence of Christianity of the first two centuries. Respecting its relation to the *Octavius* of Minucius Felix much has been written; to the present writer it seems unquestionable that Tertullian's work was the later. Of great moment also is the *De Præscriptione Hæreticorum*, in which the jurist is more clearly heard than the Christian. The *De Spectaculis* and *De Idololatria* show that Tertullian was already in a certain sense a Montanist before he formally went over to that creed; on the other hand, his *De Pœnitentia* proves that his earlier views on church discipline were much more tolerant than his later. To learn something of his Christian temper we must read the *De Oratione* and the *De Patientia*. The *De Baptismo* is of special interest from the archæological point of view.

---

[1] Compare also the judgment of Hilary and of Vincent of Lerins, *Commonit.*, 24.

II. *Works written between* 202–203 *and* 207–208.—*De Virginibus Velandis, De Corona Militis, De Fuga in Persecutione, De Exhortatione Castitatis, Scorpiace adv. Gnosticos* (?), *Adversus Hermogenem, De Censu Animæ adv. Hermogenem* (lost), *Adv. Valentinianos, Adv. Apelleiacos* (lost), *De Paradiso* (lost), *De Fato* (lost), *De Anima, De Carne Christi, De Resurrectione Carnis*, and *De Spe Fidelium* (lost), were all written after Tertullian had recognized the prophetic claims of the Montanists, but before he had left the church.

III. *Works later than* 207–208.—To this period belong the five books *Adv. Marcionem*, his main anti-Gnostic work (in the third form—the first of the five was written in 207–208), *Ad Scapulam* (a memorial to the governor, written soon after 211), *De Pallio* (possibly this ought to be classed among the earliest writings), *Adv. Praxean* (his principal work against the Monarchians), and *Adv. Judæos*. The latest extant works of Tertullian (all after 217) are his controversial writings against the laxity of the Catholics, full of the bitterest attacks, especially upon Calixtus, the bishop of Rome; these are *De Monogamia, De Jejunio, De Pudicitia*, and *De Ecstasi Libri VII.* (lost). The arguments against the genuineness of some of the above writings do not seem to the present writer to have weight. It is uncertain whether Tertullian was the author of the *Acta Perpetuæ et Felicitatis*.

Literature.—A thoroughly adequate edition of the works of Tertullian and a full account of his fortunes as a writer are still desiderata; the best edition at present is that of Oehler (3 vols., Leipsic, 1853). The *editio princeps* is by Beatus Rhenanus (Basel, 1521); others have appeared by Gelenius (1550), Pamelius (1579), De la Barre (1580), Rigaltius (1634), Semler (1770–71), Oberthür (1780), Leopold (1839 *sq.*), and Migne (1844). The Vienna Academy is about to publish an edition by Reifferscheid. There are German translations by Besnard (1837) and Kellner (1882), and an English translation appears in Clark's Ante-Nicene Theological Library. Separate treatises of Tertullian have often been edited,—the *Apologeticus* by Havercamp (1718), Oehler (1849), and Kayser (1865); the *Ad Nationes* by Godofredus (1635); the *De Spectaculis* by Klussmann (1877); the *De Testimonio Animæ* by Lindner (1862); the *De Pallio* by Salmasius (1656); other minor writings by Hurter, etc. The testimonies of the church fathers (the most important being those of Cyprian, Eusebius, Jerome, and Vincent of Lerins) are partly brought together in the editions.

The older studies on Tertullian by Le Nourry, Tillemont, Dupin, Allix, Cave, Ceillier, Mosheim, Centner, Semler, Noesselt, are to some extent reproduced in vol. iii. of Oehler's edition. Among the more modern contributions to the subject may be mentioned those of Neander (*Antignosticus: Geist des Tertullians*, Berlin, 1825), Böhringer (*Die Kirche Christi in Biographien*, vol. iii., 2d ed., 1875), Möhler (*Patrologie*, vol. i., 1840, pp. 701–789), Kaye (*Eccles. Hist. of the 2d and 3d Centuries, illustrated from the writings of Tertullian*, 3d ed., 1845), Coenen (*Comment. de Tertull.*, Utrecht, 1825), Hesselberg (*Tertullian's Lehre*, pt. i., Dorpat, 1848), Ebert (*Gesch. d. Christl. Lit.*, 1874), Freppel (*Tertullien*, Paris, 1864), Hauck (*Tertullian's Leben u. Schriften*, 1877), Alzog (*Patrologie*, 3d ed., 1876); see also the manuals of church history, history of dogma (*e.g.*, Harnack's *Lehrb. d. Dogmengesch.*; also Schwane's, Dorner's, and others), of Roman literature (Teuffel), of Christian philosophy (Ritter, Stöckl, Erdmann, Ueberweg). Compare also Deutinger, *Geist d. Christl. Ueberlieferung*, vol. i.

On the chronology and genuineness of the works attributed to Tertullian, see Mosheim, Semler, Noesselt (*De Vera Ætate et Doctrina Scriptorum Tertulliani*, 1768; in Oehler's ed., vol. iii.), Uhlhorn (*Fundamenta Chronologiæ Tertull.*, Göttingen, 1852). Bonwetsch (*Die Schriften Tertullian's n. d. Zeit ihrer Abfass.*, Bonn, 1879), Kellner ("Zur Chron. Tert.'s," in *Theol. Quartalschr.*, 1870–71), Grotemeyer (*Ueber Tertullian's Leben u. Schriften*, Kempen, 1863–65), Harnack ("Zur Chronol. d. Schr. Tert's," in *Ztschr. f. Kirchengesch.*, 1878), Nöldechen ("Tert.'s Geburtsjahr," in *Ztschr. f. wiss. Theol.*, 1886). On Tertullian as a man, a citizen, and an author, see Ebert (as above), Engelhardt ("Tert.'s schriftstell. Character," in *Ztschr. f. d. hist. Theol.*, 1852), Ritter (in Braun and Achterfeld's *Bonner Zeitschrift*, Hft. 8), Hildebrand (in Jahn's *Jahrb. z. Alterthumswissensch.*, 1843), Dieringer (*Doctrina Turtulliani de Rep. et de Offic. et Jur. Civium Christianorum*, Bonn, 1850), Nördechen ("Tert. als Mensch u. als Bürger," in *Hist. Ztschr.*, 1885), Schmidt (*De Latinitate Tert.*, Erlangen, 1870–72). Klussmann, (*Curarum Tertull.*, pts. i., ii., Halle, 1881), Hauschild (*Die Grundsätze u. Mittel der Wortbildung bei Tert.*, Leipsic, 1881), and Langen (*De Usu Tert. Præpositionum*, Münster, 1869). On Tertullian as a jurist, see Blumenbach (*De Presbytero et Icto Tertulliano*, Leipsic, 1735), Wiesenhavern (*De Icto Tertulliano*, Hildesheim, 1743), Pagenstecher (*De Jurispr. Tert.*, Harderwijk, 1768), Rudorff (*Röm. Rechtsgesch.*, i. p. 196 *sq.*). On Tertullian as an apologete, see Hefele ("Tert. als Apologet," in *Beitr. zur Kirchengeschichte*, vol. i.), Jeep ("Tert. als Apologet," in *Jahrbb. f. deutsche Theol.*, 1860), Pelet (*Essai sur l'apolog. de Tert.*, Strasburg, 1868), Condamin (*De Tertulliano Vexatæ Religionis Patrono*, Bar-le-Duc, 1877), Werner (*Gesch. d. apolog. u. polemisch. Lit.*, vols. i., ii., 1861–62). On his relations to the Greek apologists, see Harnack (*Texte u. Unters. z. altchrist. Lit.-Gesch.*, vol. i.); on those to Minucius Felix, Ebert (*Tert.'s Verhältniss zu M. Felix*, Leipsic, 1868), and a number of other discussions by Hartel, Kühn, etc. His relations to Clement of Alexandria have been investigated by Munscher (in Henke's *Magazin*, vol. vi., 1796), Nöldechen (*Jahrbb. f. prot. Theol.*, 1886; *Theol. Stud. u. Krit.*, 1886); on his relations to Irenæus, Hippolytus, Melito, and the Gnostics, see Harnack (*Zur Quellenkritik der Gesch. d. Gnosticismus*, Leipsic, 1873), Lipsius (*Die Quellen der ältesten Ketzergesch.*, 1875), Harnack (*De Apellis Gnosi Monarchica*, Leipsic, 1874, and *Texte u. Untersuch.*, vol. i.), Hilgenfeld (*Ketzergesch.*, 1884), and Hagemann (*Die röm. Kirche*, 1864). His relations to the Greek element in general are treated of by Caspari in vol. iii. of his *Quellen zur Gesch. d. Taufsymbols* (1875), and those to the New Testament and primitive Christianity by Rönsch (*Das N. T. Tert.'s*, 1871), Volkmar (in Credner's *Gesch. d. NTlichen Kanon*, 1860), Westcott (*Hist. of the Canon of the N. T.*, 5th ed., 1881), Charteris (*Canonicity*, 1880), Overbeck (*Die Auffassung d. Streits zwischen Petrus u. Paulus bei den Kirchenvätern*, Basel, 1877), Barth ("Tert.'s Auffassung des Ap. Paulus," etc., in *Jahrbb. f. prot. Theol.*, vol. viii.), and Nöldechen ("Ein geflügeltes Wort bei Tert.," in *Ztschr. f. wiss. Theol.*, 1885).

On Tertullian as a Montanist, see Gottwald (*De Montanismo Tert.*, Breslau, 1863) and the accounts of Montanism by Schwegler, Baur, Ritschl, Bonwetsch, De Soyres, Salmon, Harnack, and others; also Noldechen ("Die Krisis in Karthag. Schleierstreit," in *Ztschr. f. kirchl. Wissensch. u. kirch. Leben*, 1886). On his relation to the creed and rule of faith consult Harnack (*Patr. App. Opp.*, i., 2d ed., ii. Appendix, and *Lehrb. d. Dogmengesch.*, vol. i.). His doctrine of the Eucharist has been discussed by Dieringer (in *Der Katholik* for 1864), Leimbach (*Beitr. z. Abendmahlslehre Tert.'s*, Gotha, 1874), and in the standard works on the history of the doctrine generally. For his doctrine of the resurrection, see Oehninger (*Tert. u. seine Auferstehungslehre*, Augsburg, 1878); for his psychology, see *Der Katholik* for May, August, and September, 1865, Murton (*Essai sur l'origine de l'âme d'après Tert.*, Strasburg, 1866), Burckhardt (*Die Seelenlehre des Tert.*, Bautzen, 1857), Stöckl (*De Tert. Doctrina Psychol.*, Münster, 1863), and Hauschild (*Tert.'s Psychologie*, Frankfort-on-Main, 1880). On his doctrine of the original state of man, see Wendt (*Die Lehrs von d. menschl. Vollkommenheit*, 1882), and Nöldechen (*Ztschr. f. wiss. Theol.*, 1885); and on his doctrine of redemption, see Bordes (*Exposé crit. des opin. de Tert. sur la redemption*, Strasburg, 1860). The treatise *Adv. Praxean* and his anti-Monarchian polemic are discussed by Lipsius (*Jahrbb. f. deutsch. Theol.*, 1868) and Hagemann (as above), and in the church histories; his conception of the sacraments by Leimbach (*Theol. Stud. u. Krit.*, 1871). His ethical ideas are analyzed by Münscher (Henke's *Magazin*, vol. vi., 1796) and Nielsen (*Tert.'s Ethik*, Copenhagen, 1879); the *De Pallio* by Kellner (*Theol. Quartalschr.*, 1870), the *De Patientia* by Nöldechen (*Ztschr. f. kirchl. Wissensch. u. kirch. Leben*, 1885), the *Adv. Judæos* by Semler, Bonwetsch (as above), and Volkmar (in Credner's *Gesch. d. NTlichen Kanon*), the spurious addition to the *De Præscriptione* by the authorities already cited for his relations to Gnosticism and by Lipsius (*Zur Quellenkritik des Epiphanios*, 1865). On the poem *Adv. Marc.*, falsely ascribed to Tertullian, see Hückstädt's monograph (Leipsic, 1875), also the *Ztschr. f. wiss. Theol.*, 1876; on the poem *De Sodoma et de Jona*, see Müller (*Rhein. Mus.*, xxii.). The passages of archæological importance in Tertullian are discussed by Leimbach in *Ztschr. f. die hist. Theol.*, 1871, and by Nöldechen in *Ztschr. f. kirchl. Wissensch. u. kirchl. Leben*, 1885; see also Morcellus (*Africa Christiana*, 3 vols., Brescia, 1816), Münter (*Primordia Ecclesiæ Africanæ*, Copenhagen, 1829), and Görres ("Das Christenthum u. der Staat z. Zeit des Kaisers Septimius Severus," in *Jahrbb. f. prot. Theol.*, 1878). Some editions of individual works of Tertullian, as well as philological investigations not mentioned in the foregoing list, will be found particularized in Mayor's *Bibliographical Clue to Latin Literature*, 1875.

(A. HA.)

TERUDANT, or **TARUDANT**. See MOROCCO, vol. xvi. p 860.

TERUEL, a province of Spain, forming part of the ancient kingdom of Aragon, is bounded on the N. by Zaragoza, on the E. by Tarragona, on the S. by Castellon de la Plana and Valencia, on the S.W. by Cuenca, and on the W. by Guadalajara, and has an area of 2363 square miles. It is intersected from east to west by the mountain chains of Albarracin and Gudar, from which several offsets diverge on either side. The loftiest summit is the Muela de San Juan (5280 feet), which is covered with snow for a great part of the year. These sierras give rise to several large rivers, the principal being the Tagus, the Gualadaviar, the Jiloca, and the Guadalope. Notwithstanding the fertile character of the plains and an abundance of mineral wealth, the trade of the province is unimportant, and civilization in a backward state, owing to the lack of means of transport, the want of enterprise, and imperfect communication with the outer world. The chief products are corn, wine, oil, cheese, fruits, timber, flax, hemp, silk, wool, and saffron, together with cattle, sheep, and swine; while in the busier centres some slight manufacture of coarse cloth, paper, leather, soap, pottery, and esparto goods is carried on. The population of the province in 1877 was 249,000.

TERUEL, the capital and most important town of the above province, is situated on the left bank of the Guadalaviar, 142 miles east of Madrid, and on the high road from Calatayud to Valencia. It is an ancient walled city, fast falling into decay, with narrow gloomy streets and crumbling mediæval houses. Some of the numerous churches are worth seeing, with their paintings by the rarely known 17th-century artist Antonio Visquert, as is also the great aqueduct of 140 arches, raised 1555–60 by Pierre Bedel, a French architect. In the cloisters of San Pedro lie the remains of the celebrated "lovers of Teruel," Juan de Marcilla and Isabella de Segura, whose pathetic story has formed the subject of numerous dramas and poems by Perez de Montalvan, Yaque de Salas, Hartzenbusch, and others. The cathedral is Churriguerésque. Teruel was raised to the dignity of a see in 1577, the bishop being suffragan of Zaragoza. The population of the city in 1877 was 9482.

TESCHEN (Polish *Cieszyn*), the chief town of a duchy in Austrian Silesia, is situated on the Olsa, a tributary of the Oder, 34 miles southeast of Troppau. It combines both Polish and German peculiarities in the style of its buildings, and contains five churches, the most interesting of which are the parish church, which formerly belonged to a Dominican monastery, and the Gnadenkirche, one of the Protestant churches built in terms of the treaty of Altranstädt in 1706. The only relic of the ancient castle is a square tower, dating from the 12th century. The manufacturing industry of the town is slight, and, since the construction of the railway *via* Oderberg, Teschen has lost much of the trade formerly commanded by its position near the borders of Silesia, Hungary, Moravia, and Galicia. A flax dressing and spinning factory, a large brewery, and several furniture factories are the chief industrial establishments in the town. The population in 1880 was 13,004.

It was at Teschen that Maria Theresa and Joseph II. signed the peace which put an end to the war of Bavarian succession in 1779. The duchy of Teschen was formerly a more or less direct apanage of the Bohemian crown. For some time it bore the name of Saxe-Teschen (Sachsen-Teschen), owing to the fact that Prince Albert of Saxony, who married an archduchess of Austria, received it as part of his wife's dowry. Prince Albert bequeathed it in 1822 to the emperor of Austria who bestowed it on the archduke Albert.

TESSIN. See TICINO.

TEST ACTS. The principle that none but persons professing the established religion were eligible for public employment was adopted by the legislatures of both England and Scotland soon after the Reformation. In England the Acts of Supremacy and Uniformity and the severe penalties denounced against recusants, whether Roman Catholic or Nonconformist, were affirmations of this principle. The Act of 7 Jac. I. c. 2 provided that all such as were naturalized or restored in blood should receive the sacrament of the Lord's Supper. It was not, however, until the reign of Charles II. that actual receiving of the communion of the Church of England was made a condition precedent to the holding of public offices. The earliest imposition of this test was by the Corporation Act of 1661 (13 Car. II. st. 2. c. 1), enacting that, besides taking the oath of allegiance and supremacy and subscribing a declaration against the Solemn League and Covenant, all members of corporations were within one year after election to receive the sacrament of the Lord's Supper according to the rites of the Church of England. This Act was followed by the Test Act of 1672 (25 Car. II. c. 2). The immediate cause of the Test Act (the full title of which is "An Act for preventing dangers which may happen from popish recusants") was the king's declaration of indulgence, dispensing with laws inflicting disabilities on Nonconformists. This Act enforced upon all persons filling any office, civil or military, the obligation of taking the oaths of supremacy and allegiance and subscribing a declaration against transubstantiation, and also of receiving the sacrament within three months after admittance to office. The Act did not extend to peers; but in 1678 30 Car. II. st. 2 enacted that all peers and members of the House of Commons should make a declaration against transubstantiation, invocation of saints, and the sacrifice of the mass,—a special exception being made in favor of the duke of York. The provisions of the Test Act were violated by both Charles II. and James II. on the ground of the dispensing power claimed by the Stuart kings. In a well-known case of Godden *v.* Hales (11 *State Trials*, 1166), an action for penalties under the Test Act brought against an officer in the army, the judges decided in favor of the dispensing power,—a power finally abolished by the Bill of Rights. After a considerable number of amendments and partial repeals by the legislature of the Acts of 1661, 1672, and 1678, and of Acts of indemnity to protect persons under certain circumstances from penalties incurred under the Test Act the necessity of receiving the sacrament as a qualification for office was abolished by 9 Geo. IV. c. 17, and all Acts requiring the taking of oaths and declarations against transubstantiation, etc., were repealed by the Roman Catholic Relief Act of 1829 (10 Geo. IV. c. 7). This general repeal has been followed by the special repeal of the Corporation Act by the Promissory Oaths Act, 1871 (34 and 35 Vict. c. 48), of the Test Act by the Statute Law Revision Act, 1863, and of the Act of 1678 by 29 and 30 Vict. c. 19. Religious tests remained in the English universities until 1871. To be a member of the Church of England was a necessary condition precedent for holding most university or college offices by the Act of Uniformity of 1662, and such offices were not affected by the Toleration Act of 1689 and the Roman Catholic Relief Act of 1829. In 1871 the University Tests Act abolished subscriptions to the articles of the Church of England, all declarations and oaths respecting religious belief, and all compulsory attendance at public worship in the universities of Oxford, Cambridge, and Durham. There is an exception confining to persons in holy orders of the Church of England degrees in divinity and positions restricted to persons in holy orders, such as divinity and Hebrew professorships.

Scotland.—A religious test was imposed immediately after the Reformation. By 1567, c. 9, no one was appointed to a public office or to be a notary who did not profess the Reformed religion. The Scotch Test Act was 1681, c. 6, rescinded by 1690, c. 7. Renunciation of popery was to be made by persons employed in education (1700, c. 3). A motion to add, after the 18th article of union, an exemption of Scotsmen from the sacramental test in the United Kingdom was negatived by the Scottish parliament. A similar fate awaited a proposal that while a sacramental test was in force in England all persons in public office in Scotland should subscribe their adhesion to the Presbyterian Church government. By 1707, c. 6, all professors, principals, regents, masters, or others bearing office in any university, college, or school in Scotland were to profess and subscribe to the Confession of Faith. All persons were to be free of any oath or test contrary to or inconsistent with the Protestant religion and Presbyterian Church government. The reception of the communion was never a part of the test in Scotland as in England and Ireland. The necessity for subscription to the Confession of Faith by persons holding a university office (other than that of principal or professor of theology) was removed by 16 and 17 Vict. c. 89. The Act provides that in place of subscription every person appointed to a university office is to subscribe to a declaration according to the form in the Act, promising not to teach any opinions opposed to the divine authority of Scripture or to the Confession of Faith, and to do nothing to the prejudice of the Church of Scotland or its doctrines and privileges.

Ireland.—An oath of allegiance was required by the Irish Act of Supremacy (2 Eliz. c. 1). The English Act of 3 Will. and M. c. 2 substituted other oaths and enforced in addition from peers, members of the House of Commons, bishops, barristers, attorneys, and others a declaration against transubstantiation, invocation of the Virgin Mary and the saints, and the sacrifice of the mass. By the Irish Act of 2 Anne c. 6 every person admitted to any office, civil or military, was to take and subscribe the oaths of allegiance, supremacy, and abjuration, to subscribe the declaration against transubstantiation, etc., and to receive the Lord's Supper according to the usage of the Church of Ireland. English legislation on the subject of oaths and declarations was adopted in Ireland by Yelverton's Act, 21 and 22 Geo. III. c. 48, § 3 (Ir.). These provisions were all repealed by the Promissory Oaths Act, 1871. The Roman Catholic Relief Act of 1793 (33 Geo. III. c. 21, Ir.) excepted Trinity College, Dublin, from its provisions, and tests existed in Dublin university until 1873. They were abolished as far as regarded certain scientific professorships in 1867 by 30 Vict. c. 9, and were finally abolished for the whole university by the University of Dublin Tests Act, 1873, except as to professors of and lecturers in divinity.

United States.—By art. 6 of the constitution, "no religious test shall ever be required as a qualification to any office or public trust under the United States." A similar provision is generally included in the State constitutions.[1]

TESTAMENT. See WILL.

TESTIMONY. See EVIDENCE.

TETANUS (from Gr. τείνω, I stretch), a disorder of the nervous system, consisting in an increased reflex excitability of the spinal cord and manifesting itself by painful tonic spasm of the voluntary muscles throughout the body. The disease shows itself under various conditions. It occasionally occurs, particularly in tropical countries, without apparent cause, and has thus been known to affect numbers of persons simultaneously (*idiopathic tetanus*). It is sometimes observed in new-born children (*trismus neonatorum*) and in parturient women (*puerperal tetanus*). But by far the greater number of cases occur in connection with a wound or other injury, more especially in the extremities, probably implicating some of the peripheral nerves. Certain forms of injury, as punctured, lacerated, and gunshot wounds, are more liable to be followed by tetanus than others. In many cases the liability bears no proportion to the extent of the wound. Exposure to cold after injury is an important exciting cause. The symptoms of tetanus in its most usual forms generally appear during the healing process of a wound, but occasionally they arise after cicatrization is completed. Sometimes they are preceded by appearances of irritation in the wound or its neighborhood, but this is exceptional. The earliest indications of the disease usually show themselves, no matter where the wound is situated, by stiffness about the muscles of the jaw, causing difficulty in opening the mouth, which soon increases to lockjaw or trismus. This is accompanied by spasm in neighboring muscles, and the drawn features and exposed teeth give to the countenance the peculiar expression known as *risus sardonicus*. The rigidity extends to the muscles of the neck, back, chest, abdomen, and extremities, and the body frequently assumes a bent attitude, either backward (*opisthotonos*), forward (*emprosthotonos*), or laterally (*pleurosthotonos*). This general muscular rigidity, which at first is not constant but occasionally undergoes relaxation, is accompanied by frequently recurring convulsive seizures, which are readily excited by the slightest irritation, such as from a draught of cool air, a bright light, the closing of a door, etc. In such attacks there is great suffering and the expression of the face is indicative of agony; and the function of respiration may be seriously involved and asphyxia threaten or actually take place. The temperature of the body sometimes rises to a high degree. The attack is usually acute and after a few days either passes off or, as is more frequent, terminates fatally, either by asphyxia from tonic spasm of the respiratory muscles or from exhaustion consequent on the violence of the symptoms together with the absence of sleep. Throughout the whole course of the disease the mind is clear. In idiopathic tetanus the symptoms are less severe, the course more chronic, and recoveries more common than in those which depend upon a wound or injury. The puerperal form, with symptoms which differ in no way from those described, is rare and occurs either after parturition or after abortion. Tetanus in new-born children, also a rare form, usually shows itself a day or two after birth by obvious difficulty in the acts of sucking and swallowing; by the supervention of trismus, together with tonic contraction of the muscles of the limbs and body, sometimes accompanied by convulsive seizures; and by a peculiar low whining cry, seldom absent and very characteristic. Various opinions have been held as to the cause of this form of tetanus, some referring it to the wound produced by severance of the umbilical cord, others to pressure upon the bones of the head in parturition, etc. It has not yet been satisfactorily explained. Although sometimes recovered from, it is usually fatal.

The symptoms of poisoning by strychnine bear a strong resemblance to those of tetanus. They are, however, more acute and develop in connection with something which has been taken; further, the absence of a wound and the fact that the spasm affects the muscles of the extremities first, and not those of the jaws, as in tetanus, serve to establish the diagnosis. In HYDROPHOBIA (*q.v.*), which in certain of its symptoms resembles tetanus, the absence of trismus, the dread of water, and the violent spasms on attempting to drink, together with the history of the case, readily enable a distinction to be made. Various other forms of nervous disease accompanied by tetanic symptoms, such as cerebro-spinal meningitis, hysteria in some forms, etc., may be still more clearly distinguished from true tetanus.

The pathology of tetanus is referred to in the article PATHOLOGY (vol. xviii. p. 399). No constant changes are observed in the body after death from tetanus. The most common are great dilatation of the blood-vessels of the spinal cord and sometimes evidence of inflammatory action, but these are probably the effects of the symptoms rather than their cause.

For the treatment of tetanus many remedies have been employed. Where a source of irritation in or about a wound can be made out, it ought to be dealt with by the surgeon. Of medicinal agents those which diminish the reflex excitability of the spinal cord and relax the spasm are to be recommended. But it is not safe to employ all substances which produce these effects. Thus tobacco and its active principle nicotine act powerfully in this way, but they are attended with danger from their poisonous properties, and the same may be said of curari, conium, calabar bean, etc., all of which have been used in tetanus. Opium carefully administered sometimes produces a markedly beneficial effect, as does also Indian hemp. Chloroform or ether inhalation greatly mitigates the severity of the spasm. Chloral hydrate and bromide of potassium or ammonium are among the most useful agents which can be employed, and they may be given separately or, still better, in combination. As adjuvants, the warm bath, the absence of all noise and excitement, and the maintenance of the strength by appropriate nutriment should not be neglected.

TETRARCH (τετράρχης), the ruler of a tetrarchy (τετραρχία), that is, in the original sense of the word, of one quarter of a region. The title of tetrarch is familiar from the New Testament as borne by certain princes of the petty dynasties which the Romans allowed to exercise a dependent sovereignty within the province of Syria. In this application it has lost its original precise sense, and means only the ruler of part of a divided kingdom, or of a region too narrow to support a higher title. After the death of Herod the Great (4 B.C.) his realm was shared among his three sons; the chief part, including Judæa, Samaria, and Idumea, fell to Archelaus (Matt. ii. 22), with the title of ethnarch; Philip received the northeast of the realm, and was called tetrarch; and Galilee was given to

[1] [Each State in the Union has supreme control over and some retain religious tests. The subject has been examined by Dr. Philip Schaff in *Church and State in the United States* (Putnam, N. Y., 1888).—AM. ED.]

Herod Antipas, who bore the same title (Luke iii. 1). These three sovereignties were reunited under Herod Agrippa from 41 to 44 A.D. Another tetrarchy is mentioned in Luke iii. 1, viz., that of Lysanias in the little district of Abilene, near Damascus, in the valley of the Barada. An inscription of this Lysanias is given in *C. I. Gr.*, 4521.

TETUAN (*Teṭṭáwin*), a town of Morocco, about 23 miles south-southwest from Ceuta and 44 southeast from Tangiers, is picturesquely situated about 9 miles inland on the steep slope of a hill, behind which rise the bold Rif Mountains. It is surrounded by walls flanked with towers, and has on the summit of the hill a castle which is the residence of the governor. The streets are narrow, unpaved, and dirty, and with few exceptions the houses are poor. Some of the numerous mosques, however, are handsome. The principal manufactures are gun-barrels, coarse woollen cloths, and woollen and silk sashes. The harbor of Tetuan, at the mouth of the Martil, allows only small vessels to cross the bar, and the roadstead is much exposed to the east. There is some export trade in cattle, grain, fruit, leather, and wool, principally to Gibraltar. The population of Tetuan is estimated at about 20,000 (5000 Jews).

Tetuan is said to have been founded in 1492 by refugees from Granada. It was taken by storm on 4th February, 1860, by the Spaniards under O'Donnell, but restored to Morocco when peace was concluded.

TEUTONES, or **TEUTONI**, a powerful German tribe, first appearing in history along with the CIMBRI (*q.v.*). They are again mentioned at a later period by Pliny (*H.N.*, xxxvii, 11) and others as inhabiting a district in the northwest of Germany to the north of the Elbe. The name of Teutones was never employed either by the Germans themselves or by the Romans as a general name for the whole German nation.

TEUTONIC LANGUAGES. See GERMANY (vol. x. p 461 *sq.*); also ENGLISH LANGUAGE (vol. viii. p. 350), GOTHS (vol. x. p. 757 *sq.*), SCANDINAVIAN LANGUAGES (vol. xxi. p. 381 *sq.*), FRISIANS (vol. ix. p. 692), and HOLLAND (vol. xii. p. 87 *sq.*).

TEUTONIC ORDER, THE, or **TEUTONIC KNIGHTS OF ST. MARY'S HOSPITAL AT JERUSALEM** (*Deutscher Orden, Deutsche Ritter, Orden der Ritter des Hospitales St. Marien zu Jerusalem*), is one of the three great military and religious orders to which the crusades gave birth. Its name is derived from a German hospital founded at Jerusalem in 1128, which disappeared on the capture of the Holy City by the Saracens in 1187. The pity excited in the minds of some German merchants by the sufferings of the Christian soldiers at the siege of Acre in 1190 induced them to revive the work of this society under a somewhat different form; and eight or nine years later the society, as thus resuscitated, was converted into a military order. Like the two other military orders, the Teutonic order adopted the Augustinian rule of life; and, in addition to the ordinary monastic vows, the members laid upon themselves the special obligations of tending sick and wounded pilgrims and of fighting the pagans. Frederick, duke of Swabia, took the young order under his protection, and it soon received charters from the pope and emperor, entitling it to the same privileges as the Templars and Knights of St. John. Whatever was the case at first, the members of the order were ultimately required to be Germans of honorable birth. Priest brothers were introduced about 1220, and afterwards half-brothers, like the *frères servants d'armes* of the other orders, who did not require to be of noble birth, and might, to some extent, continue their ordinary secular occupations. The distinguishing garb of the order consisted of a white mantle with a black cross.

Almost at once a rich stream of benefactions of all kinds began to flow into the coffers of the order, which gradually acquired extensive territories in Palestine and also in Germany and other parts of Europe. Its first seat was at Acre, and the first grand-master was a Rhenish knight named Hermann Walpot of Bassenheim. The order rose to great power and influence under Herman von SALZA (*q.v.*), who held the office of grand-master from about 1210 to 1239, and enjoyed the fullest confidence of both emperor and pope. He was also keen enough to see the hopelessness of the attempt to expel the Mohammedans from the Holy Land, and eagerly hailed the opportunity of transferring the activity of the order to another sphere which was afforded by the invitation to undertake a crusade against the heathen Prussians. The successful progress of this crusade, the aggrandizement thereby accruing to the order, and its subsequent decline have already been narrated in the article PRUSSIA (vol. xx. p. 10). Soon after the beginning of the struggle, in 1237, the Teutonic order absorbed the order of the Brothers of the Sword, a union which brought Courland, Semgallen, and Livonia to swell its territories.[1] In 1291, when Acre, the last stronghold of the Franks in Palestine, fell, the order removed its headquarters to Venice; but, when its centre of gravity became so obviously shifted to the extensive territories won from the Prussians, the seat of government was transferred (1309) to MARIENBURG (*q.v.*) on the Vistula, where a splendid castle was erected for the grand-masters. The grand-mastership of Weinrich von Kniprode (1351–82) is the most prosperous period in the history of the order. Its territorial possessions far exceeded those attained by either of the rival orders, stretching from the Oder on the west to the Gulf of Finland on the east, and containing a population of two to three million souls. Its government at first was excellent, and for a time it may be said to have played the leading rôle in the political history of northern Europe. Wherever the order spread, Christianity and German national life were introduced. Its revenues were very large, and its ranks were kept full by hosts of aspirants to a share in its pious and lucrative crusades.

So long as the order maintained its own high standard all went well with it. But its internal decay was synchronous with external events that would alone have been extremely perilous. The union of Poland and Lithuania in 1386 raised up a jealous neighbor, whose power it was wellnigh impossible in the long run to resist, while the nominal conversion of the latter to Christianity struck at the root of the order's prosperity by depriving it of its mission. When there were no more heathens within reach to convert and despoil, the chief attraction to outsiders to join its ranks disappeared. After the conversion of Prussia into a secular duchy the Teutonic order still continued to exist as an ecclesiastical organization, possessing eleven bailiwicks in different parts of Europe, with a total area of 850 square miles and 88,000 inhabitants. The headquarters were fixed at Mergentheim in Swabia. Its political importance was of course now a thing of the past, and the scattered position of the bailiwicks only emphasized its weakness. In 1801 the bailiwicks to the west of the Rhine were absorbed by France, and in 1809 the order was entirely suppressed by Napoleon, its lands going to the secular principalities within which they lay. In 1840 the order was resuscitated in Austria, where it now exists as a semi-religious knighthood, presided over by a royal archduke. Of late it has been doing something towards justifying its existence and connecting itself with its past history by engaging in the ambulance service in time of war. The bailiwick of Utrecht, which survived the decree of Napoleon, also still exists, but the Dutch representatives of the order have become Protestants. The jewel of the order consists of a black and white cross, surmounted by a helmet with three feathers.

The complete organization of the Teutonic order included a grand-master (*hochmeister*), provincial masters (*landmeister*) for the greater provinces, and commanders (*komtüren*) for the smaller districts and castles. The power of these officers was not, however, absolute. The grand-master co-operated with a chapter consisting of the provincial masters and five other important functionaries, while the provincial masters in turn had to consult with the council formed by the knight commanders. The privileges enjoyed by the order in its palmy days were of the most extensive nature, and its relations to both church and state were often of a most exceptional nature.

TEWKESBURY, an ancient borough and market-town of Gloucestershire, England, is situated in a fine pastoral valley at the junction of the Severn and the Upper Avon, and on the Midland and Great Western Railways, 15 miles south of Worcester, and 126 northwest of London. It has three principal streets, which are regularly built and well paved. The Severn is crossed by an iron bridge with a flattened arch of 170 feet span, erected by Telford in 1826. Of the great Benedictine abbey, one of the richest foundations in England, refounded and enlarged by Sir Robert Fitz-Hamon in the 12th century on the site of the ancient hermitage and Saxon monastery, there only remain the gate and part of the cloisters. The abbey church, consecrated in 1125, is a magnificent specimen of Early Norman. This elaborate cruciform building consists of nave and side aisles, with transepts united by a grand central tower richly arcaded. The choir terminates in an apse and is surrounded by an ambulatory. One of the most remarkable features of the building is the unique western front, the central part of which is occupied by one vast arch extending from the ground to the roof. Originally it was filled in with Norman windows, but these were removed in the 14th century, when the whole building underwent restoration in the Middle Decorated style, of which it is one of the finest existing examples. The nave was refilled by tracery windows, and stone groining was substituted for the carved wooden ceiling, a like transformation taking place in the transepts. The old Norman columns in the choir still exist; but above them rises a grand superstructure of Decorated work. The elegant clerestory windows are of the 14th century, with stained glass of the same date. The ambulatory was rebuilt some distance farther out, and from it projected a beautiful series of chapels. The elaborate tombs include those of Sir Robert Fitz-Hamon, the De Spensers, Alan prior of Canterbury, Sir Guy de Brien, and the vault of George duke of Clarence (murdered in the Tower) and his wife Isabella. Edward, prince of Wales, slain after the battle of Tewkesbury (1471) by the Yorkists, is also buried in the church,[1] which has undergone an extensive process of restoration under the direction of Sir Gilbert Scott. In the High Street there are several ancient timbered and gabled houses. Remains of an ancient wall have been discovered adjoining the town. The principal modern buildings are the town-hall, the philharmonic hall, and the corn exchange. There is a free grammar-school and a number of charities, including the dispensary, the rural hospital, and Queen Mary's, Barnes's, Richardson's, and Russell's almshouses. Formerly Tewkesbury had a woollen trade and an important mustard manufacture, but it is now chiefly dependent on its agricultural trade. The population of the municipal borough (area, 2619 acres) in 1871 was 5409, and in 1881, 5100.

The town is supposed to derive its name from Theoc, a Saxon monk, who founded a hermitage here in the end of the 7th century, which was changed into a monastery by the duke of Mercia in 715, and rebuilt by Sir Robert Fitz-Hamon in 1102. On the death of Fitz-Hamon in 1147 the manor passed to the De Clares, who became merged in the De Spensers, they in turn in the Beauchamps, and the Beauchamps in the Nevilles. At Tewkesbury took place, 4th May, 1471, the battle between the Yorkists and Lancastrians which placed the crown on the head of Edward IV. During the Civil War the town was occupied by the Parliamentarians, who were driven out by the Royalists; but it was surprised and captured by the former in 1644, after which it remained in their possession. Tewkesbury was first incorporated by Elizabeth in 1574, and when James I. sold the manor to the corporation in 1609, he granted it a new charter with extended privileges. This being lost during the Civil War, a new charter was granted by Charles II. Between 1692 and 1698 the town was without a corporation, but a new charter was granted by William III., which remained the governing charter until the passing of the Municipal Act. Until 1867 Tewkesbury returned two members to the House of Commons; from 1867 to 1885 it returned one; and in 1885 it became merged in the north or Tewkesbury division of Gloucestershire.

The *Annales de Theokesberia* (1066–1263) are published in *Annales Monastici* edited by H. R. Luard, 1864.

Plate III.

Boundaries.

TEXAS, the largest in area and the eleventh in population of the United States of America, is bounded by the Gulf of Mexico on the S.E., by Louisiana and Arkansas on the E., by Arkansas and the Indian Territory on the N., the latter extending north of its northern prolongation (the Panhandle), by New Mexico on the W. and N. of its western prolongation (the trans-Pecos region), and by Mexico on the S.W. Its area in 1880 was 262,290 square miles, or one-eleventh (nearly 9 per cent.) of the entire area of the United States. The extreme length is 740 miles, the breadth 825, and the coast line 400 miles. The boundaries, as recognized by the United States Government,[2] are the Gulf of Mexico from the Rio Grande to the Sabine river, the Sabine river to 32° N. lat., thence the meridian of 94° 10′ to the Red river of Louisiana, thence following that river west to its intersection with the 100th meridian, thence north to lat. 36° 30′, thence west to 103° W. long., thence south to lat. 32°, thence west to its intersection with the Rio Grande, which river constitutes the southwestern border of the State to the Gulf of Mexico.

Physical features and divisions.

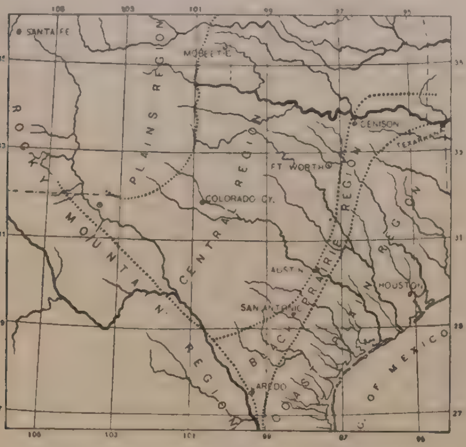
The surface features are exceedingly varied, the prevailing elements being steppes or treeless plains in the northwest, mountains west of the Pecos river, forests in the east, marshes adjacent to the coasts, low prairies in the southeast, and a combination of prairies and broken hills, interspersed with forest growth and thickets of tall shrubs (chaparral), in the centre. These regions are classified as follows (see map below). (1) The coast plain is the direct geographical and geological continuation of the other States which border on the Gulf of Mexico. It includes all the country east of a line concentric with the coast, drawn from Texarkana in the northeast corner of the State to near Laredo on the Rio Grande. The general direction of its slope, in common with that of the rest of the State, is from northwest to southeast. Its altitude ranges up to 500 feet. The immediate coast strip is newly made marsh-land; west of this and north of the Colorado river are forests; and to the south of it the country is mostly a plain. (2) The black prairie region succeeds the coast plain on the west. Its western border is sharply defined from the Red river to the Rio Grande, begining at Denison, passing through or near the cities of Sherman, Dallas, Waco, Austin, and San Antonio, and then deflected westward to Eagle Pass. It is a gently undulating prairie, covered with a rich black soil, and varies in altitude from 300 to 700 feet. (3) The central region extends from the black prairie region on the east to the eastern escarpment of the great plains on the northwest and the trans-Pecos mountains on the southwest. This is the only region of Texas which is not the direct continuation of the physical features of some adjoining political division. A great variety of conditions is embraced within its bounds. In its northeastern part are two long belts of stunted forests (the Cross Timbers), extending from the Red river to the Brazos, and separated by a prairie 50 miles in width. This is the most fertile portion of the entire region. West of this sub-region and north of the

---

[1] [The tomb of this Edward cannot be indentified.—Am. Ed.]

[2] The State does not recognize the South Fork of the Red river as the northern boundary, but insists upon the North Fork; it also claims the 100th meridian as laid down upon Mellish's map (100 miles east of the true meridian) as the eastern border of the Panhandle.

Colorado is a broken, arid country (the Coal-measures), having a sandy, pebbly soil, covered with a scattered growth of vegetation. West of this, between the 100th meridian and the escarpment of the plains, is the gypsum country, consisting of the so-called "red-beds" of the western United States, accompanied by massive deposits of gypsum and other salts. This country is much sculptured by erosion, and in places resembles the "bad lands" of the upper Missouri country. There are also extensive intervals of prairie here. Near the centre, in the counties of San Saba, Mason, and Llano, is a rough, semi-mountainous area of older formations. The southern half of the central region is a broken country of white limestone formation, semi-tropical in climate, and covered with scraggy vegetation, its physical features graduating into those of northern Mexico. The southwestern part is a rolling plain, entirely destitute of streams. Throughout the region, at intervals of many miles, low, truncated hills (*buttes*) occur, representing the remains of limestone formations now being rapidly eroded. The region, as a whole, is poorly watered. It is best adapted for cattle and sheep raising, and is the chief locality of those industries in Texas. The altitude varies from 700 to 2500 feet. (4) The plains region is the portion of the State west of the 101st meridian and north of the thirty-second parallel, commonly known as the "Staked Plain" (Llano Estacado). It is the direct southern continuation and termination of the great plains of the North American continent which extend along the eastern slope of the Rocky Mountains from British America to the Rio Pecos. The eastern edge is well marked by a steep escarpment, which, in consequence of destructive erosion, is constantly receding to the westward. The surface is smooth, and utterly devoid of forest growth or streams of water. But there are many small ponds or lakes, and in the southern part these are saline. The soil is light, rich, and porous, and is covered with a good growth of grass. Until a few years ago this region was totally unpeopled, but many portions of it are now (1887) used for grazing purposes, water being secured by means of wells or artificially constructed reservoirs. The altitude ranges from 2500 to 4000 feet. (5) The trans-Pecos or mountainous region west of the Pecos river is composed of numerous mountain peaks and ranges, with intervening valleys of many miles in width. It is poorly watered, and the population outside the immediate Rio Grande valley is very sparse. The general level of the country is from 3000 to 5000 feet.



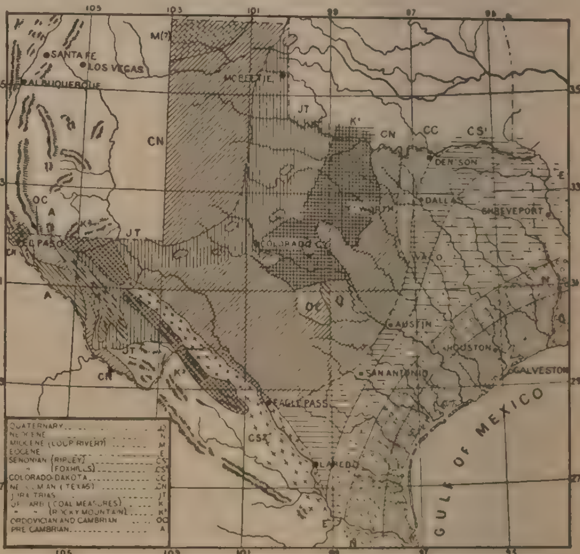
Map showing geographical divisions.

Rivers.

The rivers are separable into several sub-systems. The Rio Grande and the Arkansas, constituting the north and south limits of the Texas drainage system, with their respective tributaries, the Pecos and the Canadian, originate in a limited district of northern New Mexico and Colorado, and ultimately reach the sea at points a thousand miles apart. The Canadian and the Pecos have cut deep cañons through the Llano Estacado. The former continues eastward through Indian Territory, and the latter southward, joining the Rio Grande between 101° and 102° W. long. on the southern border of the State. The Rio Grande and the Pecos receive no tributaries of importance in Texas, but are constant in their flow. The next and most important group comprises the Red, the Brazos, and the Colorado, all of which originate along the eastern border of the Llano. They traverse similar regions, and have a general resemblance in character of sediment, irregularity of flow, velocity, and topography of drainage basins. Their brackish water is principally derived from the sudden precipitation of rainfall along the gypsiferous escarpments of the Llano. Its volume is ordinarily small, the flow often ceasing entirely west of the black prairie region. There are periodic freshets, however, which suddenly swell the volume to enormous proportions. These freshets, laden with the rich red loam of the plains, usually reach the lower inhabited sections of the State in periods of drought, and are termed "red rises." Much of this sediment is deposited upon the flood plane of the lower valleys, and by this process the most valuable sugar and cotton lands of the coast plain have been built up. Another important group consists of the Sabine, the Trinity, the San Marcos, the Guadalupe, and the Nueces, most of which have their origin near the western border of the black prairie region. These streams have a greater volume and are more constant in flow than any others, and are usually without deep cañons or wide bottoms. Many of them, especially those south of Austin, have their origin from large springs situated along the foot of the escarpment line extending from Austin southwestward. Another subsidiary system of streams originates in the narrow Quaternary region along the coast, within the district of the greatest rainfall. These streams are tidal, and sometimes navigable towards their mouths. Most of them are locally known as bayous. In general, the rivers of Texas are not adapted for irrigation or navigation. Neither do they afford much available water power north of Austin.

Geology.

The entire geologic series, with a few exceptions, is represented in Texas. The earlier Palæozoic rocks, including the pre-Cambrian (Keweenawian; A in accompanying geological map), the Potsdam (OC), and the Ordovician (OC), up to the Trenton, underlie the State, but are only exposed in two limited districts. The first of these is in the counties of Mason, Llano, Burnet, and San Saba in the central region; the other is in the disturbed mountainous portion of the trans-Pecos region. The Cambrian was deposited horizontally upon the upturned Keweenawian, and the Ordovician appears to rest conformably upon the Cambrian (Potsdam); but there was a continental elevation of the whole region, probably commencing at the close of the Trenton epoch, which continued until the beginning of the Coal-measure epoch, for the Upper Silurian, Devonian, and sub-Carboniferous are absent, and the earlier rocks are disturbed. These earlier Palæozoic sediments present no marked stratigraphical or palæontological differences from the same formations throughout the continent, and thus show the widely distributed uniformity of conditions which then existed. At the commencement of the Carboniferous period, however, that marked difference of faunal, lithological, and stratigraphical features began which distinguishes the synchronous



Geological map of Texas.

deposits of the later formations of the western and eastern portions of the United States. The Texas region has been the transition ground, and hence all the geologic deposits, beginning with the Carboniferous, have two faces, dependent upon their geographical position east or west of 100° W. long., and representing the sediments either of interior continental basins or of the waters of the Atlantic during alternating periods of submergence and emergence. The Carboniferous rocks, and most of the succeeding formations, are exposed in two widely separated portions of the State, with entirely different lithological and faunal aspects. The mutual relations of these series have never been traced. The first occurs in the central region between 97° and 100° W. long., north of the Colorado river, and consists of clays, sandstones, conglomerates, limestones, and coal seams of workable thickness. It is the southwestern prolongation and termination of the Coal-measures of the eastern United States. These rocks, although in general similar to them, differ in some respects from those of the same formation further east, and also exhibit a few resemblances to the strictly marine Carboniferous of the Rocky Mountain region (K^2). To the other series belongs the trans-Pecos Carboniferous (K^1). Although this is of the same geologic age as the eastern Coal-measures, it is a purely marine deposit of limestones and sandstones, and is barren of vegetable remains. It is exposed along the Guadalupe and other mountains of the trans-Pecos region, forming the most eastern outcrops of the non-coal-bearing Carboniferous of the west. The study of the areal distribution and relation of the strata intervening between the Carboniferous and the fully identified Cretaceous in Texas has not been begun. The Permian, Triassic, and Jurassic, if they exist, have not been clearly diagnosed, although these names have been applied to the series of rocks west of the central Carboniferous region. The thickness of the sediments belonging to these undetermined strata is very great. They are mostly unfossiliferous, and the presence of stratified gypsum and other salts indicates that they were laid down in an interior basin cut off from oceanic waters and were too highly concentrated for the existence of molluscan life. Certain of these deposits, known as "red beds" or "Jura-Trias" (JT), extend beneath the Llano Estacado, across New Mexico, and into Arizona. The Cretaceous is by far the most conspicuous and extensive of the geologic formations of the State. It once covered the entire territory, but has been eroded away in many places west of the black prairie region, exposing the older formations, and is covered to the east of that region by more recent deposits. From the fact that the lowest member of the series is found resting directly upon the pre-Cambrian in Llano county, the Carboniferous in Lampasas and the counties northward, the Silurian in the trans-Pecos region, and the Jura-Trias beds in the plains region, it is evident that its beginning marked a period of continental submergence, and that this submergence, from the great thickness of pelagic sediments in it, was long continued. The lowest member of the series, the oldest known of the American Cretaceous, is unknown elsewhere in the United States, and its peculiar features give individuality to the central region. This member (CN), which may be called the Texas group, is the equivalent of the Neocomian of Europe, and many of its fossils are common to Europe and America. It is not exposed east of the central region, except (probably) in the salines of Louisiana. There was a great elevation of this deep-sea formation at its close, as is attested by the shallow water sediments of later groups deposited unconformably upon it. The Middle (CC, CS^1) and the Upper Cretaceous (CS^2 and CS^1) are also well exposed. The black prairie region is underlain by the middle and upper groups of the marine Cretaceous characteristic of the other Gulf States and known as the Rotten Limestone (CS^1) and Ripley (CS^1) groups. The Cretaceous groups of the Rocky Mountain region extend into Texas, and are exposed in the trans-Pecos region and along the lower Rio Grande. The Tertiary formations, so far as recognized, are purely marine, and, like the marine Upper Cretaceous of the black prairie region, are the direct geographical continuation of the formations of the other Gulf States. They occupy the coast plain, in bands approximately concentric with the shore of the Gulf of Mexico, and represent the sediments of its receding waters. The alleged occurrence of the fresh-water Miocene, the Loup river group (M), upon the Llano Estacado has not been demonstrated. Quaternary (Q) and other recent alluvial deposits occur along the coast and the upper terraces of the three older river systems as far west as the eastern border of the central region. This is attested by the character of the deposits, accompanied by well-authenticated remains of the elephant and mastodon. These Quaternary soils are mostly the redeposited detritus of the strata of the eastern escarpment of the Llano Estacado, which is carried down by the "red rises." The surface features of the central region are the result of sub-aerial denudation. The black prairie is protected from this destructive erosive process by the tenacious character of its soil; and the coast plain is covered by a luxuriant forest growth, and is constantly extending eastward by the recession of the shore line. The final emergence of the State began in Middle Cretaceous time, and was connected with the same movements that brought up the Rocky Mountain system. The strata of Texas, except the Palæozoic groups, are soft, and yield readily to disintegration. A few eruptive sheets are found in the trans-Pecos region and along the lower Rio Grande, being remnants of the eastern edge of the great eruptive area of the Rocky Mountain region. Granitic masses occur, as extrusions from the pre-Cambrian, in the central and trans-Pecos Palæozoic deposits.

Mountains.

The eastern ranges of the Rocky Mountain system are deflected towards the Gulf of Mexico after passing south of 33° N. lat., and take a southeasterly course through Texas into Mexico, the trend of their axes being generally parallel to the direction of the Rio Grande and its principal tributaries. The only true mountains in Texas are situated west of the Pecos, with the exception of a few foot-hills (*lomitas*) which re-enter the State from Mexico near Eagle Pass and follow the river to an undetermined point below Laredo. The principal ranges are the Guadalupe, Limpia, Chinali, Los Chisos, Organ, and Franklin Mountains. They are composed of older rocks, in most places; the later formations have been washed away, except where protected by eruptive flows. The most eastern and northern of these mountains are usually the highest. Guadalupe Peak is 9000 feet; Limpia Peak and the crest of the Chinalis, from 3500 to 8000 feet; Eagle Mountains, 7000; and the intervening valleys from 3500 to 5000 feet. The low buttes of the central region are miscalled mountains upon most maps. There are several well-defined escarpments extending for long distances, approximately north and south. The step of the first of these, from Austin to Eagle Pass, is from 200 to 500 feet high, and is the result of an elevation at the close of the early Cretaceous period. Near the 100th meridian another escarpment occurs, and along the eastern and southern borders of the Staked Plain still another. The western part of the coast plain has a few low hills. The rest of the State has no notable prominences.

Minerals.

The mineral resources of Texas have not been mapped or studied, and hence the State ranks last in mineral products. The trans-Pecos region is rich in silver and lead ores; but the State owns the mineral rights of nearly all the land, and has hitherto declined to open them to development. Only one mine is worked here. Silver and gold have also been discovered and mined in Llano and Mason counties, but without successful results. Gold occurs throughout the marine limestones of the lowest (Texas) group of the Cretaceous, but not in sufficient quantity for profitable extraction. Rich but not abundant copper ores occur in the drift of the gypsum country. Iron ore is found in the Tertiary of eastern Texas, and is profitably reduced in a few charcoal furnaces by the aid of convict labor. At present these are remote from coal and suitable means of transportation. Magnetic iron ore occurs in the pre-Cambrian rocks of Mason county, and recent analyses show it to be equal in quality to the best Swedish ores. It is in great abundance, but remote from means of transportation and fuel. Ores of iron (sphæro-siderite) occur in the central Carboniferous formation, but their commercial value is unknown. The non-metals occur in great abundance in different portions of the State, including salt, gypsum, magnesium sulphate, natural cements, kaolin, and other clays. The unutilized beds of massive gypsum are, with the exception of those of the Sahara and the Andes, the purest and most extensive in the world. Salt is gathered from lacustral deposits or mined at El Paso, Colorado City, and along the lower Gulf coast for local use. The coals of the central Carboniferous area have been worked to some extent, but are generally of inferior quality, having from 50 to 70 per cent. of ash. Very recent discoveries of better quality have been reported. Tertiary fibrous lignite, of light specific gravity, is found in great abundance all along the junction of the coast plain and black prairie regions. It is worked to a small extent, but has no commercial value. The most important coal area is the semi-bituminous lignite belt of the trans-Pecos and lower Rio Grande regions, which is the direct geographical continuation of the late Cretaceous coals of New Mexico and Colorado. It is worked at Eagle Pass and Santa Toma, near Laredo. The beautiful marbles and other ornamental stones of the State are untouched, with the exception of the Llano county granite.

The amount and regularity of the rainfall decreases inland, the mean annual varying from 52.3 inches at Galves-

Climate.

ton to 13 at El Paso in the extreme west and 23 at Mobeetie in the extreme north. The subjoined table gives the mean temperature and rainfall of certain representative localities:

The coast plain and the black prairie regions have abundant rainfall for agricultural purposes. It decreases, however, to the west, and varies greatly in different years, sometimes being ample; but in 1885–86 it did not average 10 inches. The precipitation is also very sudden, seldom lasting more than a few minutes at a time. Only 52 per cent. of the 20 inches of rainfall in the central region and west of it falls in the agricultural season, one-half being in summer and the remainder in autumn, so that it is equivalent to only 15 inches in regions where the rainfall occurs in more propitious seasons. This condition is, however, especially favorable for grazing. There are few statistics of the plains region; but the rainfall along its eastern escarpment is slightly greater and more regular than that of the central region. The temperature varies greatly throughout the State, both in extremes and means. Fort Ringgold on the lower Rio Grande is the hottest point in the United States, except Key West, Fla. Its mean temperature is 73.4° Fahr.; that of El Paso is 63°, and of Mobeetie 54.6°. The prevalent winds are southerly and southeasterly, and blow constantly across the State, without which its summers would be unendurable. The Rio Grande valley is not subject to frosts. Snow seldom falls south of Galveston and Austin. In the Panhandle the winters are severe.

Flora.

The arboreal flora of Louisiana and Arkansas extends into northeastern Texas, conformable with the coast plain, where, immediately south of the Colorado river the great pine belt of the Atlantic and Gulf coasts terminates. The flora of the great plains region, principally consisting of nutritious grasses, enters the northwestern portion of the State and extends south to the 32d parallel and east to the 101st meridian. The peculiar plants of the Rocky Mountain plateaus penetrate into the trans-Pecos region, while the north Mexican flora is found along the Rio Grande. The central region is a transition ground where these floras find representation generally in deteriorated and dwarfed species. In the coast plain occur the long and short leaf pine, with many species of oak and hickory. The black prairie region is destitute of trees, except scattered individuals of live oak and the mesquite bush (*Prosopis glandulosa*). The broad river valleys of this region, however, are well-timbered with pecan, cypress, cottonwood, and several species of oak, and have a vigorous growth of smaller shrubs. West of the black prairie region the dwarfed, stunted trees are of little value except for fuel. The river valleys have the same character of trees as further east, but the rocky highlands are covered with scraggy bushes (chaparral) of oak, juniper, and cedar. The summits of the Guadalupe and Limpia ranges, in the trans-Pecos region, are clothed with forests of the yellow (*Pinus ponderosa*), flexible (*P. flexilis*), and nut pine (*P. edulis*), all of which attain great size. Many smaller trees grow on these mountains. The valleys and several of the ranges in the last-named region, however, are destitute of trees. The entire Rio Grande valley, from El Paso to Brownsville, grows many species of cactus and other prickly, coriaceous shrubs. The grasses of the State are especially numerous in species, and are found most luxuriantly on the prairies of the lower coast, the central, and the plains regions. The lumber supply of the State comes entirely from the east Texas pine forests. The cedar, juniper, and mesquite are only utilized for fuel and fencing.

Fauna.

The black bear (*Ursus americanus*), cougar (*Felis concolor*), and lynx (*Felis rufa*) are common to all parts of the State. The bison, wild horse, prongbuck (*Antilocapra americana*), coyote (*Canis latrans*), gray wolf (*C. lupus*), eastern prairie dog (*Cynomys ludovicianus*), and the lesser *Mammalia* of the great Rocky Mountain plains constitute the fauna of the northwestern part of the State, reaching into the western part of the central region. Their southern limit is approximately the 31st parallel. The highest ranges of the trans-Pecos region possess the unique avian and mammalian fauna of the Rocky Mountains, including the black-tailed and the mule deer (*Cariacus macrotis*) and Rocky Mountain sheep, with a few Mexican species. The lower valleys have a mingling of the Mexican, Rocky Mountain, and great plain faunas. Along the valley of the Rio Grande, and extending northward in places, the subtropical fauna is Mexican, including the peccary (*Dicotyles torquatus*), armadillo (*Dasypus peba*), jaguar (*Felis onca*), and ocelot (*Felis pardalis*). Among the birds are the scissor-tail (*Milvulus forficatus*), Mexican eagle (*Polyborus cheriway*), chaparral cock (*Geococcyx viaticus*), and numerous other unique forms. The fauna of the humid wooded coast plain is the southwestern continuation and termination of that of the South Atlantic and Gulf States, with slight variations, and includes the Virginia deer (*Cariacus leucurus*), raccoon (*Procyon lotor*), opossum (*Didelphys virginiana*), alligator, etc. The black prairie region limits the last named fauna on the west, except in its wooded river bottoms. The central region possesses representatives of the great plains, Rocky Mountain, Mexican, and Louisiana faunas, but none of them cross it into other regions. It is a true transitional ground of most of the faunas of all temperate North America, east of the Pacific slope.

Population.

The total population in 1880 was 1,591,749 (837,840 males and 753,909 females), and in 1887 it was estimated to have risen to 2,415,000, giving 9.2 inhabitants to the square mile. Of the population in 1880 1,477,133 were natives of the United States and 114,616 foreign born. There were 393,384 Negroes, 136 Chinese, 992 Indians, and 43,000 civilized aborigines (Mexicans). Of the entire population 522,133 persons were engaged in occupations as follows: In agriculture (including stock-raising), 359,317 (68.8 per cent.); in law, medicine, and other professions, 97,651 (18.7 per cent.); in trade and transportation, 34,909 (6.7 per cent.); in manufacturing and mining, 30,346 (5.8 per cent.). At the same date there were 3153 prisoners, 2276 idiots, 1564 insane, 533 paupers, 1375 blind, and 771 deaf. 13.9 per cent. of the native whites, 24.7 of the foreigners, and 75.4 of the Negroes—or 29.7 per cent. of the entire population—were unable to read or write. The population of Texas has increased more rapidly than that of any State in the Union except Kansas. The following table shows the increase for the past few decades:

Year.	Anglo-American.	Negro Descent.	Mexican Aboriginal Descent.	Indians.	Europ'ns.	Asiatic.	Total Population.	Per cent. Increase.
1850	...	...	...	...	...	...	212,592	...
1860	420,891	182,921	...	403	...	...	604,215	184.2
1870	564,700	253,475	...	379	62,411	25	818,579	35.4
1880	1,197,237	393,484	43,000	992	114,116	136	1,591,749	94.4
1887	...	...	...	...	200,000	300	2,415,000	94.4

The population of the principal cities, according to the U. S. census of 1880 and trustworthy estimates in 1886, was as follows:

	1880.	1886.		1880.	1886.
Galveston	22,248	30,000	Austin	11,013	23,000
San Antonio	20,550	35,000	Fort Worth	6,663	25,000
Dallas	10,358	32,000	Waco	7,295	20,000
Houston	16,513	23,000	Denison	3,975	12,000

84 per cent. of the total population of the State is found east of the central region—the black prairie region (northern half) being the most densely populated, and the coast plain next. Between 1880 and 1887 there was a large flow of

population into the trans-Pecos and plains regions, and during the last two years mentioned a decrease in the central region. The population consists principally of white natives of the southern United States, except in the counties of Brazos, Fort Bend, Harrison, Marion, Moore, and Washington, where it is of Negro race; in the counties of Fayette, Colorado, Guadalupe, Comal, and Gillespie, where it is German; and along the Rio Grande, where it is Mexican.

Agriculture.

Of the United States Texas now ranks first in the production of cotton and cattle, second in sugar, sheep, mules, and horses, eighth in rice and pigs. The eastern third of the State, containing 80 per cent. of the entire population, is agricultural; the remainder is pastoral. The chief crops are cotton and Indian corn; wheat is grown in the northern part of the black prairie and eastern part of the central regions, sugar in the lower bottom lands of the Brazos and the Colorado, rice on the coast. The chief vegetable products for 1880 were—cotton, 805,284 bales; Indian corn, 29,065,172 bushels; wheat, 2,567,737; oats, 4,893,359; sweet potatoes, 1,460,079; Irish potatoes, 228,832; barley, 72,786; rye, 25,399; sugar, 4951 hogsheads; molasses, 810,605 gallons; hay, 59,699 tons; tobacco, 221,283 pounds; rice, 62,152 pounds; orchard products, to the value of $876,844. The total value of these products was $63,076,311. Since 1882 the quantity of cotton produced annually has exceeded 2,000,000 bales, of 500 pounds each. In 1880 there were 174,184 farms in the State, with an aggregate of 12,650,314 acres of improved land. The farms are usually of large size, and garden, orchard, and dairy products are entirely secondary to plantation crops. The southern part of the coast plain and the rest of the State west of the black prairie region are peculiarly adapted to pastoral pursuits, which are entirely separated from agricultural, the cattle and sheep being allowed to roam at large, or enclosed in enormous pastures, where they subsist without other food or shelter than nature affords. In 1880 there were in the State—4,084,605 cattle, 2,411,633 sheep, 1,950,371 pigs, 805,606 horses, and 132,447 mules and asses. The sheep walks are more particularly confined to the southern half of the central region, including the lower Rio Grande valley.

Commerce.

The exports are cotton, wool, and hides, most of which are shipped from Galveston or sent overland by rail. The chief imports are manufactured articles used in the State, also coal and railway material. Apart from a small retail trade along the border, there are no exports to the adjoining States. The principal seaport and commercial city is Galveston. The mileage in railways has increased from 1048 in 1872 to 5974 in 1882, and to 7034 in 1886.

Education.

The founders of the State made liberal provision, by grants of land and revenue, for public education, but their intentions have not been carried out by subsequent legislation. Texas occupies the anomalous position of having the best school fund and the poorest school system in the United States. The public free school system proper consists of two normal schools for the preparation of teachers, and numerous district schools, open for four months in the year. In most of the cities the State fund is supplemented by local taxation, and excellent schools are maintained. In 1886 there were 489,795 children within school age, and the cost of the maintenance of the whole system was $2,362,226. There are no schools for secondary education, except the high schools of a few cities. The State university is at Austin; it is abundantly endowed with lands, but does not receive the full benefit of its revenues. There is also a State agricultural and mechanical college, but technical training is made secondary.

Administration.

The State government differs somewhat from those of the rest of the Union, owing to the fact that it has had to adapt itself to the administration of the great public domain, by which most of the public institutions are supported and works of internal improvement accomplished, and because much of the attention of the Government has been necessarily diverted to the protection of its extensive frontier. The executive government consists of a governor, comptroller, treasurer, commissioner of the general land office, and superintendent of education, elected biennially, with an attorney-general and a secretary of state, appointed by the governor. The judiciary consists of two courts of final appeal, one for criminal, the other for civil business; forty itinerant higher courts for the trial of penal offences and civil suits; courts for misdemeanors and minor civil cases in each county; and innumerable justices' courts for first hearings. The legislature consists of 32 senators elected for four years, and 115 members of the house of representatives elected for two years. It is restricted by the constitution to biennial sessions of ninety days each. The State is divided into thirteen congressional and forty judicial election districts. It is also divided into 232 counties, 75 of which have no population, or insufficient population to be organized. Each county is divided into four commissioners' precincts and a varying number of school, election, and justices' precincts. The State has always maintained a corps of troops, formerly for protection against Indians, but now for preserving order in the unorganized counties. It has institutions for the blind, deaf and dumb, and insane. The prison system is far superior to that of the other southern States, but still very imperfect. The bonded debt of the State on 1st January, 1887, was $4,237,730, and its taxable wealth $600,000,000. The aggregate debt of all the counties and cities was $7,000,000. The homestead and exemption laws are unusually liberal to the debtor.

History.

The upper Rio Grande valley was visited in 1580–83 by the Spaniards, who established missions among the settled Indians near El Paso and Santa Fé. The first white settlement was made by La Salle at Lavaca, on the coast, in 1685. The country was inhabited by Indians of various tribes, both savage and agricultural, most of whom are now extinct, except the so-called "Mexican" population of the Rio Grande. From 1583 to 1794 many missions were established by Roman Catholic missionaries among the Indians, who were completely alienated from their original language, religion, domestic habits, and tribal relations. After the purchase of Louisiana from the French in 1803 Anglo-American adventurers began to cross into Texas from the United States. In 1821, when Mexico threw off the Spanish yoke, Texas and Coahuila constituted a state of the republic. It was shortly after this that the first American colonists were permitted to enter the territory under Government patronage. Within ten years over 20,000 had settled between the Sabine and the Colorado. In 1830 the Mexican Government placed them under military rule, from which, with accompanying impositions, originated the war of Texan Independence. The Anglo-Americans were assisted by volunteers from the United States, and the war was terminated by the defeat of the Mexicans under General Santa Anna at San Jacinto, 21st April, 1836. From 1837 to 1845 Texas was an independent republic. It was admitted to the United States on 29th December, 1845, in spite of the protests of Mexico, and a war with that country immediately ensued. The new State sold to the United States Government for $10,000,000 all the territory west and north of the present boundaries between the headwaters of the Rio Grande and the Arkansas. But it reserved the control and disposal of the public lands within its borders, which have proved a magnificent source of revenue, and also the right to divide into five states, should future growth and development justify it. By a small majority the State seceded from the Union in 1861. In 1868 a new constitution was adopted, and the State readmitted into the Union. In 1874 the Kiowa and Comanche Indians, who had prevented the settlement of the central and plains regions from the earliest times, were subjugated.

TEXTILES.[1]

Method of weaving.

TEXTILES.[1] This word is applied to all fabrics which are woven in a loom, of whatever material they may be made, and whether the woven stuff be plain or figured. The simplest and earliest process of weaving was managed thus. The ground of the future stuff was formed by a number of parallel strings called the *warp*, having their upper ends attached to a horizontal beam and drawn taut by weights hung from their lower ends. In the early Greek loom each warp thread had a separate weight (see Fig. 1). On the number of the warp strings the fineness and width of the stuff depended. The strings of the *weft* were interlaced at right angles to those of the warp, and the combination of the two formed the woven stuff or *web*. The *weft* was so called from its being "wafted" in and out of the warp; it is also often called the *woof*, though more correctly the woof is the same as the web or finished stuff. The threads of the weft were wound round a sort of bobbin on a pivot which was made to revolve inside a hollow boat-shaped piece of wood pointed at both ends so as to pass easily between the threads of the warp. This is called the *shuttle*. The thread passed out through a hole in the side of the shuttle, the inner pivot revolving as the thread was delivered between the strings of the warp. In order to make the weft interlace in the warp some of the upright strings were pulled forward out of the general plane in which the warp hung; this was done in the simplest way by a reed, which divided the threads into two sets called *leaves* and thus formed an opening called the *shred*, through which the shuttle could pass, as shown in Fig. 1. Another way, applicable to more complicated ornamental weaving, was to have a series of threads attached to the warp at right angles, so that the weaver could pull any of the warp threads away from the rest, thus allowing the shuttle to pass in front of or behind any special warp strings. By a very simple mechanical contrivance these threads were worked by a foot treadle, thus leaving the weaver's hands free to manage the shuttle.[2] In the simplest sort of weaving first one and then the other half of the warp threads were pulled forward, and so a plain regularly interlaced stuff was woven. The next stage was to make a cloth with colored stripes, by using successively two shuttles containing different colored threads. In a checkered cloth the warp was made of two-colored threads stretched in successive bands, and the cross stripes of the weft were woven in by the two shuttles. To form a more complicated pattern the weft must not cross the warp alternately: the design is formed by either the warp or the weft predominating on the surface in certain places. In all cases each thread of the weft must be driven home to its place after each stroke of the shuttle. In the earliest times this was done by beating the weft with a wooden sword-shaped implement[3] introduced between the strings of the warp; but later a heavy comb-shaped tool was used,[4] the teeth of which passed between the warp and drove home at one blow a longer length of the weft. An upright loom such as has been described is shown clearly in some of the wall paintings from Thebes, dating about 1600 B.C. and in other earlier ones from Beni-Hasan. A very similar loom is represented on a Greek vase of the 5th century B.C., with a picture of Penelope and the never-finished piece of stuff (see Fig. 1). In this interesting painting the upper band has simple geometrical ornaments, such as occur on archaic Greek vases; the next has figures of winged men and gryphons. This sort of loom is still used in Scandinavian countries for tapestry.[5] Another form has the warp threads stretched, not upright, but horizontally,—an arrangement which is more convenient for working treadles. These two forms are called in French "la haute lisse" and "la basse lisse,"—the high and the low loom. The general principle is the same in both. Fig. 2 shows a simple form of the "basse lisse," such as was used throughout the Middle Ages, except in Iceland and in Scandinavia.[6] The clay whorls, or pierced cones, decorated with simple painting, which have been found in countless numbers on the sites of Troy, Mycenæ, and other prehistoric cities, were probably used to strain the thread as it was being spun on the distaff.[7] Other heavier ones were employed to stretch the strings of the warp; this method must have been very inconvenient, as the whole warp could swing to and fro. A very obvious improvement, introduced in some countries at an early date, was to have a second beam, round which the lower ends of the warp could be wound. In Scandinavian countries the use of weights continued till modern times. In the fate-loom of the sagas these weights are heroes' skulls, while the shuttle is a sword.

---

[1] This article deals mainly with the history of the textile art; for practical information as to modern processes, see WEAVING; see also EMBROIDERY, vol. viii. p. 148 *sq*.

Looms.

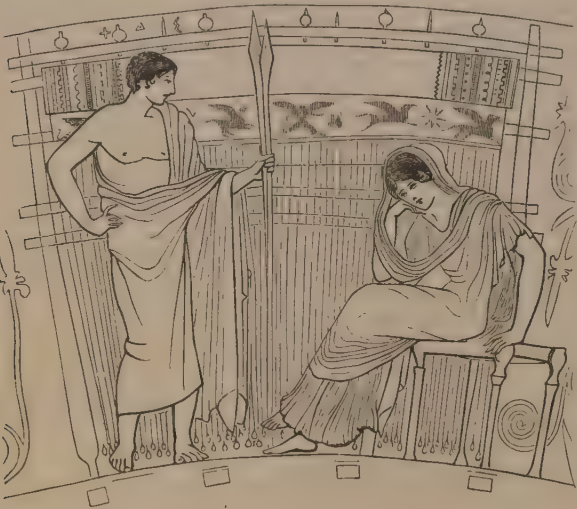

FIG. 1.—Penelope's loom, from a Greek vase of the 5th century B.C. The standing figure is that of Telemachus.[1]

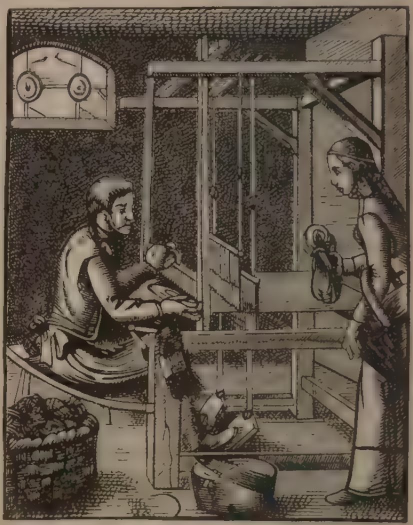

FIG. 2.—Mediæval low-warp loom, from a cut by Jost Amman; middle of the 16th century.

Prehistoric.

Some simple form of weaving seems to have been practiced by prehistoric man at a very early stage of development. Fig. 3 shows an example of coarse flaxen stuff from the lake-dwellings of Switzerland, dating from the Stone Age. Wool appears to have been the first substance used, as no skill is required to prepare it for spinning. Weaving was specially the duty of women, and even in the Middle Ages in Europe it was, in some countries, considered a specially feminine employment.[1] An early Christian sarcophagus in the Lateran has a symbolical relief representing God condemning the future world to labor,—tillage for the man and weaving for the woman: He gives ears of corn to Adam and a sheep to Eve.

---

[1] See *Mon. Inst. Arch. Rom.*, vol. ix. pl. 42.

[2] These dividing sticks are called in French "batons à deux"; in the simplest kind of weaving only one is required. The use of treadles and "spring staves" is more applicable to the low loom, in which the warp is strained in a horizontal position.

[3] Lat. *spatha*.

[4] Lat. *pecten;* modern English *batten* or *lay*.

[5] See the modern Faroese loom figured by Worsaae, *Afbildninger fra det k. Museum for Nordiske Oldsager*, Copenhagen, 1854, p. 123.

[6] A fresco by Pinturicchio—911 in the National Gallery, London—has a careful representation of the mediæval low loom; the subject is the return of Ulysses to Penelope.

[7] Dr. Schliemann found 22,000 in the plains of Troy alone.

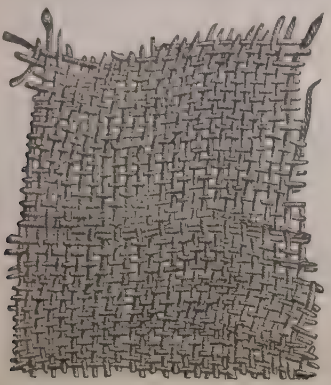

FIG. 3.—Prehistoric (Stone Age) flaxen stuff, from a lake-dwelling in Switzerland.

Ancient Egyptian.

The Egyptians were famed for the beauty of their woven stuffs, and almost incredible stories are related of the fineness of their linen, such as a pallium sent by King Amasis to the Spartans, which, Herodotus (iii. 47) says, was made of yarn containing no less than 360 threads; the figures woven on this were partly of cotton and partly of gold thread. Herodotus also mentions a wonderful pallium sent by the same king to the shrine of Athene at Lindus. Few examples of the fine and richly ornamented sorts of Egyptian stuffs now exist, though we have immense quantities of the coarse linen in which mummies were wrapped. This, though coarse, is closely woven, and usually has in every inch many more threads to the warp than to the weft.[2] A few fragments of Egyptian cloth of the XVIIIth Dynasty have been found with a border of colored bands, the blue of which is indigo, and the red extract of KERMES (*q.v.*). In Egypt linen was specially employed for religious purposes, such as priestly and royal vestments, because it harbors dirt less than wool or cotton, which were also worn by the Egyptians, and it was used to bandage mummies, because it was thought not to engender worms. Though priests were allowed to wear outer garments of wool, they were obliged to put them off before entering a sacred place.

Phœnician.

The Phœnicians were celebrated for their weaving, as for their skill in other arts. Their purple linen, dyed with the murex, was specially valued; Tyre and Sidon were the chief places where this was made. Babylon, Carthage, Sardis, Miletus, and Alexandria were all famous seats of textile manufacture in the time of Herodotus.

Assyrian.

Though no specimens of Assyrian textiles remain, some notion of their richness of ornament and the styles of their patterns may be gained from the minute representations of rich dresses worn by kings and other important personages in the sculptured wall-reliefs from Nineveh which are now in the British Museum.[3] The stuffs worn by Asurbanipal are most elaborate in design, being covered with delicate geometrical patterns and diapers, with borders of lotus and other flowers treated with great decorative skill. A large marble slab from the same palace is covered with an elaborate textile pattern in low relief, and is evidently a faithful copy of an Assyrian carpet. Still more magnificent stuffs are represented as being worn by Assyrian captives on the enamelled wall-tiles from Rameses II.'s palace (14th century B.C.) at Tel al-Yáhúdíya (see POTTERY, vol. xix. p. 620); the woven patterns are most minutely reproduced in their different colors, and the design, special to Assyria, of the sacred tree between two guardian beasts, is clearly represented, though on the most minute scale.

Greek.

Our knowledge of Greek textiles, in the almost complete absence of any existing specimens,[4] is chiefly derived from the descriptions of various classical authors. One indication of the patterns commonly used at an early period is given by the designs on much of the archaic Greek pottery, which clearly has ornament derived from textile sources. Vol. xix. p. 624, Fig. 16, shows examples of these; simple bands, chequers, and zigzags would naturally be the first steps towards more elaborate patterns. Again, recent excavations at Orchomenus and Tiryns have brought to light examples of ceiling and wall decoration, the motives of which are obviously derived from textile patterns. A stone ceiling at Orchomenus has in relief a carpet-like pattern, and the painted wall-stucco of the Tiryns palace has many varieties of coarse but effective textile ornament. The poems of Homer are full of descriptions of woven stuffs of the most magnificent materials and design, used both for dresses[5] and for tapestry hangings.[6] In later times the most important examples of rich woven work of which we have any record were certain peploi made to cover or shade the statues of the deities at Athens, Olympia, Delphi, and other famous shrines.[7] Euripides (*Ion*, 1141–1162) gives a glowing description of a peplos which belonged to the temple of Apollo at Delphi, on which was depicted the firmament of heaven, with Apollo Helios in his chariot, surrounded by the chief stars and constellations. At Athens a new peplos, ornamented with the battle of the gods and the giants, was woven for the gold and ivory statue of Athene in the Parthenon every fifth year, and was solemnly carried in procession at the greater Panathenæa. Similarly at Olympia a new peplos was woven by sixteen women, and displayed every fifth year at the Olympian games in honor of Hera. It appears probable that these magnificent peploi were not used as garments, which would have partly concealed the splendor of Phidias's gold and ivory statues, but were suspended over them like a mediæval baldacchino. Very possibly, however, most of the elaborate work on them was embroidery done by the needle, and not loom or textile work.

Roman.

The Romans under the late republic and the empire possessed immense stores of the most magnificent textiles of every description, such as the splendid collection of tapestry which Rome inherited along with the other art treasures of Attalus II. of Pergamum (2d cent. B.C.). A very costly cloth of gold was called by the Romans "attalica," after Attalus. The C. Cestius who died about the middle of the 1st century B.C., and who is buried in the existing pyramid in Rome, left orders in his will that his body was to be wrapped in certain attalica; but, as this was forbidden by a sumptuary law, his heirs sold the gold stuff and with the proceeds had two colossal bronze statues made, which were set outside the tomb. The feet of one of these have been found with an inscribed pedestal recording the above-mentioned facts. The size of the statue shows that the attalica must have been worth a very great sum. Examples of large prices given by Romans for woven stuffs are recorded by Pliny (*H. N.*, viii. 48): Metellus Scipio bought some hangings from Babylon for 800,000 sesterces [$3,265.92], and other similar stuffs were bought by Nero for four millions of sesterces (about £3360 [or $16,329.60]). Costly tapestry from Babylon is mentioned by Plautus (*Stich.*, II., ii. 54), Silius Italicus (xiv. 658), and Martial (xiv. 150). Virgil (*Geor.*, iii. 25) mentions woven tapestries with figures of Britons being used at theatrical shows: "Purpurea intexti tollant aulæa Britanni." Other tapestries with scenes from the story of Theseus and Ariadne are mentioned by Catullus (*Argon.*, xlvi. 267).[1] On a very remarkable example of late Rome stuff found at Sitten (Sion) in Switzerland is woven a graceful figure of a nymph seated on a sea-monster, among scroll-work of foliated ornament, purely classical in design.[2] A large quantity of very remarkable woven stuffs has recently been found in tombs at Ekhmin (Panopolis) in Middle Egypt. More than 300 pieces have been bought for the South Kensington Museum. They are of various dates, apparently ranging from the 4th to the 6th or 7th century A.D. The earliest are of purely classical style: some have badly designed but very decorative figures of pagan deities, with their names in Greek—*e.g.*, Hermes and Apollo; others have figures driving chariots drawn by two centaurs, or marine gods, or long bands of animals—bears, lions, stags, ducks, and many others. These are used to decorate linen tunics or pieces of stuff about 2 feet square. The later examples appear to be Coptic vestments of various shapes, and are decorated with rude figures of St. George and other Oriental saints, each with a nimbus. These ornaments are done by true tapestry weaving, the weft pattern being in brilliantly colored wools on a flaxen warp. In some cases the colors, especially the magnificent reds and blues, are as bright as if they were new. Though in all cases the figure drawing is rude, the decorative value is very great.

---

[1] In the time of St. Louis (13th century) in France some sorts of weaving, such as "tapisserie Saracenois," were done only by men.

[2] Some existing specimens have in each inch 152 threads in the warp and 70 in the weft; in modern stuffs the proportion is the other way. A coarsely woven piece of Egyptian stuff in the British Museum has a border with a man swimming, supported by a float.

[3] A very magnificent royal dress, with woven patterns of deities, kings animals, and the sacred tree, much resembling those on the metal bowls of Assyria, is figured by Layard, *Monuments of Assyria*, series i., pl. ix.

[4] One remarkable example of tapestry from a tomb in the Crimea is supposed by Stephani to date from the 4th century B.C.; see *Comp. Rend. Com. Arch.*, 1878-79, p. 40, pl. v.

[5] *Il.*, iii. 125, viii. 288, ix. 200, x. 156, xiv. 178, xxii. 440; *Od.*, ii. 93, x. 220, xiv. 61, and many passages in books xviii. to xx. Homer describes (*Od.*, xix. 225–235) a cloth of purple wool with a hunting scene in gold thread, woven by Penelope for Ulysses.

[6] *Il.*, xvi. 224, xxiv. 230, 645; *Od.*, iv. 124, 298, vii. 337. Many Greek vases, especially those with black figures and incised lines, have representations of rich woven dresses,—*e.g.*, an amphora in the Vatican with Achilles and Ajax playing at a game like draughts, *c.* 460 B.C. A rather later vase in the British Museum has a fine figure of Demeter clad in a pallium covered with figures of chariots and winged men and horses.

[7] See De Ronchaud, *Le Péplos d'Athènè*, Paris, 1872, and *La Tapisserie*, Paris, 1885. The treasuries of most Greek temples appear to have contained large stores of rich woven stuffs.

Byzantine.

From the 6th to the 13th century Byzantium became the capital of all the industrial arts, and in none is its influence more obvious than in that of weaving. There the arts of ancient Greece and of old Rome met and were fused with the artistic notions of ancient Egypt, Assyria, Persia, and Asia Minor, and this combination produced a fresh and very active art spirit, which for many centuries dominated the whole civilized world. As regards weaving, this new development was strengthened by the introduction of silk into Europe in the reign of Justinian, and many specimens of early silk fabrics have lasted down to the present time, partly through their being safe against moths. The silken stuffs found in the tombs of Charlemagne and other kings, though perhaps not themselves as early as the 6th century, show one class of design used in Byzantium in the time of Justinian. Some of these combine the figure-subjects of ancient Rome with the stronger decorative beauty of the East. Chariot races in the circus, consuls and emperors enthroned in state, gladiatorial fights with lions, and other classical subjects occur, arranged in medallions or wreaths, set in close rows, so as to fill up the ground. Again, mixed with these classical scenes are designs of purely Assyrian origin, such as the sacred tree between two guardian beasts, closely resembling the designs of 2000 B.C. The manufacture of these rich fabrics was carried on, not only in Byzantium, but also in many towns of Greece proper, such as Athens, Thebes, and Corinth, all of which were specially famed for their silk textiles.

Persian.

During the same time, the 6th to the 12th century, Baghdad, Damascus, Ispahan, and many other towns in Persia and Syria were producing woven stuffs of the richest materials and designs; names of reigning caliphs are sometimes mingled with Arabic sentences from the Koran and other sacred books, which are introduced freely among the intricate patterns with the most richly decorative effect. By this means some existing specimens of the 8th to the 10th century can be dated. Fig. 4 shows a 16th century example of the finest Persian damask in silk and gold,—a masterpiece of textile design.

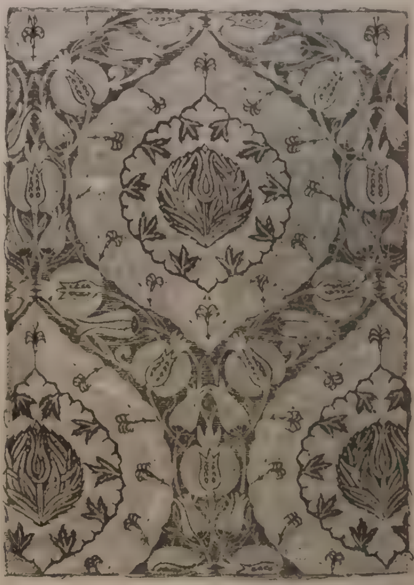

FIG. 4.—Persian damask in silk and gold. (South Kensington Museum.)

Sicilian.

According to the usual story, Roger of Sicily, who in 1147 made a successful raid on the shores of Attica and took Athens, Thebes, and Corinth, carried off as prisoners a number of Greek weavers, whom he settled at Palermo and made the founders of the royal factory for silk weaving. This story is doubtful, for the Saracenic inhabitants of Sicily had apparently been producing fine silken stuffs long before the 12th century. In part, however, the story may be true; certainly an impetus was given to the weaving industry of Palermo in the 12th century, and for about two centuries Sicily became the chief seat in Europe for the production of the finest woven stuffs. A large number of examples of these beautiful fabrics still exist, showing an immense variety of designs, all of which are imagined with the highest decorative skill,—perfect masterpieces of textile art, combining freedom of invention and grace of drawing with that slight amount of mechanical stiffness which is specially suited to the requirements of the loom. One of the earliest existing specimens, which shows the existence of the fabrique before the time of Roger I., is a piece of silk stuff in which the body of St. Cuthbert at Durham was wrapped when his relics were translated in 1104; this was found at the opening of his grave in 1827, and is now preserved in Durham cathedral library. The figures woven on it show an interesting combination of Western and Oriental art.

---

[1] See also Hor., *Sat.*, ii. 6, 102–6; Ovid, *Metam.*, vi.; and Lucr., iv. 1026.

[2] This fragment is illustrated by Müntz, *La Tapisserie*, Paris, 1882, p. 53.

Birds and conventional ornaments of purely Eastern style are mingled with designs taken from late Roman mosaics,—the whole being blended with great skill into a highly decorative pattern.[1] The Sicilian silks of the 12th to the 14th century were mostly used

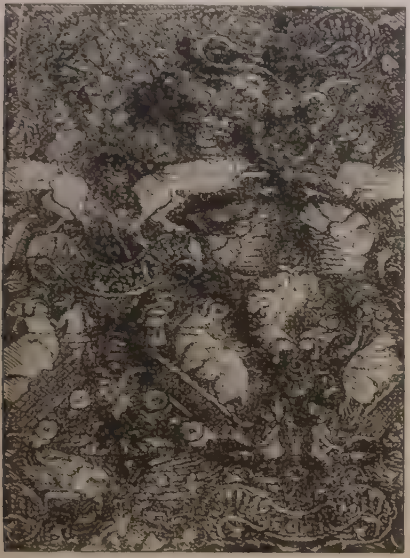

FIG. 5.—Sicilian silk stuff of the 13th century, in St. Mary's church, Dantzic.

for ecclesiastical vestments, altar frontals, and the like; and the fact that examples have survived in almost all countries of Europe shows how important and far-reaching a trade in them must once have been carried on. The favorite designs were

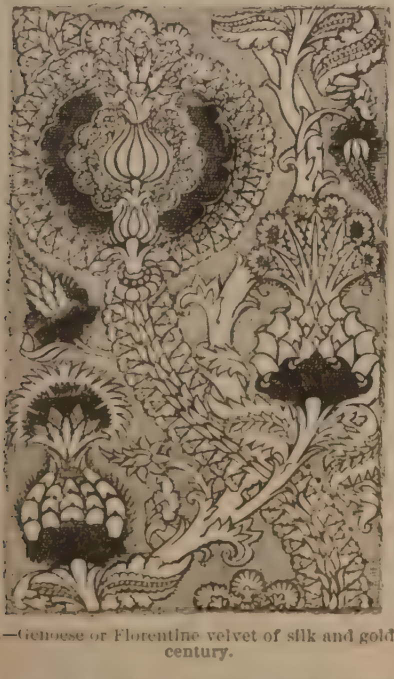

FIG. 6.—Genoese or Florentine velvet of silk and gold; 15th century.

the sun breaking through a cloud from whence rays of light are issuing, or conventionally treated ships, fountains, islands, castles, and an immense variety of birds and beasts, such as swans, mallards, eagles, lions, cheetahs, hounds, giraffes, antelopes, and others. Some specimens have siren-like female forms, with floating

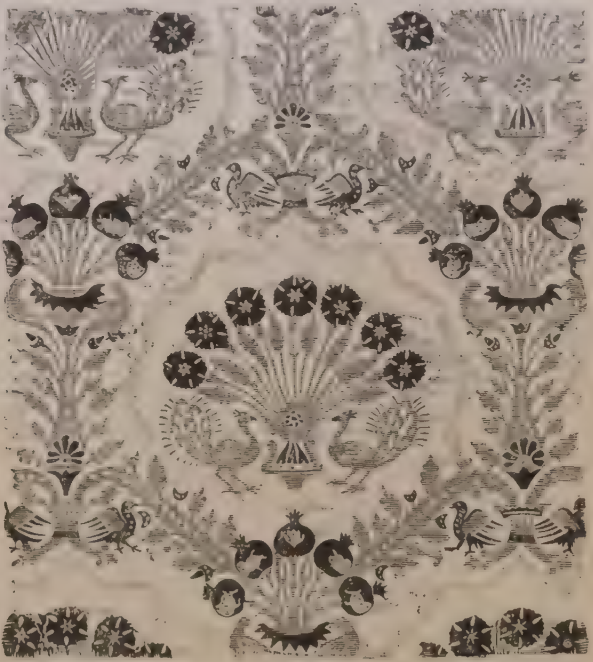

FIG. 7.—Silk stuff of Oriental design, woven at Venice in the 15th century. (South Kensington Museum.)

hair, casting nets, leaning down from palm trees, or issuing from shells. Others, rather later in style, have winged angel-like figures. In many cases the Assyrian sacred tree and its guardian beasts occur, and very frequently borders with sham Arabic letters are introduced,—a survival of the time when real sentences were woven into the fabrics of Persia and Egypt, probably intended as a visible sign that the stuff was the genuine product of Saracenic looms. All these are perfect masterpieces of textile art, and have never since been rivalled either in beauty of design or in skilful use of gold and colors. Fig. 5 shows a characteristic example; another copied from a painting is given under MURAL DECORATION, vol. xvii. p. 53, Fig. 15.

Italian.

In the 14th century the chief centre of fine silk weaving was transferred from Palermo to Lucca, Florence, Milan, Venice, and other towns in northern Italy, and a different class of design, less rich in fancy, but scarcely less beautiful in effect, came into vogue. The designs of the 14th and 15th century textiles were chiefly conventional adaptations of natural foliage and flowers, arranged with great beauty of line and wealth of decorative effect; among the most beautiful is scroll-work of vines with graceful curving lines of leaf and tendril. An extremely rich design, largely employed throughout the 15th century, was made from the artichoke plant,[2] and was especially used for the rich "cut" velvets of Genoa, Florence, and Venice, in which the pattern is formed in relief by pile raised above pile, mixed with gold[3] (see Fig. 6 and vol. xvii. p. 52, Fig. 14). At this time Venice contained a large number of Oriental craftsmen in all the industrial arts, and very beautiful stuffs were woven there with designs of mingled Oriental and Italian style,—probably the work of Mohammedan weavers (see Fig. 7).

---

[1] See Raine, *Saint Cuthbert*, Durham, 1828, plate iv.; in his text the author is wholly wrong as to the *provenance* of these stuffs.

[2] This is usually called the pine-apple pattern; but it was invented long before the discovery of America had introduced the pine-apple into Europe.

[3] Italian and Flemish pictures of the 14th to the 16th century often give most valuable representations of rich textiles; see Vacher, *Fifteenth Century Italian Ornament*, London 1886, a series of colored plates of textiles taken from Italian pictures.

Gold thread.

In all these Oriental, Sicilian, and early Italian stuffs gold thread is used in a very lavish and effective way. It was made very skilfully, the richest effect being produced with little metal by thickly gilding fine vellum skins with gold leaf; the vellum was then cut into very thin strips and wound round a thread of silk or hemp so closely as to look like a solid gold wire. In and since the 15th century gold thread has been made by twisting a thin ribbon of gilt silver around a silken core. In this way much less gold is required, as the silver ribbon is gilded before being drawn out to its final thinness, and it is thus liable to tarnish, owing to the partial exposure of the silver surface. In classical times attalica and other gold stuffs were made of solid gold wire beaten out with the hammer.[1] Masses of this fine gold wire[2] have been found in the tombs of Egypt, Greece, and Etruria, the metal having lasted long after all the rest of the stuff had crumbled into dust. In 1544 the grave of the wife of Honorius was opened and 36 ℔ of gold thread taken out of it and melted.

Gold cloth.

Throughout the Middle Ages cloth of gold was largely employed for ecclesiastical and royal purposes. In some cases the whole of the visible surface was formed of gold thread, producing the utmost splendor of effect. Westminster Abbey still possesses a magnificent gold cope of the 15th century, in almost perfect brilliance of preservation. In the 13th and 14th centuries Cyprus and Lucca were specially famed for their gold stuffs, and the royal inventories of France and England show that the kings possessed stores of this to an immense value. The enormous sum of £11 [$53.46] a yard[3] is recorded to have been given for a "cloth of estate" in the private accounts of Henry VII. This was a cloth to hang over the royal throne, and must have been unusually wide, as other cloth of gold at the same time was bought for 38s. the yard. Various names were at different times given to textiles which were wholly or in part woven in gold, such as *ciclatoun* (a word of obscure origin), *baudekin* (from Baldak or Baghdad), *nak*, and *tissue*.[4] *Samite* or *examite* (ἑξμίτοι) was so called because the weft threads were only caught and looped at every sixth thread of the warp, lying loosely over the intermediate part. Mediæval samite was sometimes made of gold; if of silk it was a variety of satin, called *satin of six*. Modern satin usually has its weft looped in less closely—*satin of eight* or *ten*.

English.

Although throughout the Middle Ages the finer stuffs used in England were to a great extent the product of foreign looms, there was no lack of native textiles, many of which were of great beauty. In the use of the needle the women of England were especially skilful, and rich English embroideries were much exported, even into Italy, from the 12th to the 14th century,[5] and were esteemed more highly than the productions of any other country. Two fine examples of early English silk and gold needlework—a stole and maniple with the inscription *Aelflæd fieri precepit: pio episcopo Fridestano*—are preserved in the Durham library. Fridestan became bishop of Winchester in 905. Other examples of native textiles have been found in the coffins of many ecclesiastics in England. Some interesting fragments are preserved in the chapter-house of Worcester cathedral; the ground is of silk, and the pattern, of conventional scroll foliage, is a characteristic example of 13th-century design. Pictures in English MSS. show that the low loom was mainly used,—this being the most convenient for ordinary weaving.[6] England was specially celebrated for its wool and woollen stuffs, and even at the present day English wool is used for the Gobelin tapestries; in the 15th and 16th centuries it was largely imported into Flanders. In the 14th century Bath produced the finest woollen cloth, and that of Worcester was equally celebrated; in the 15th century the production of woollen stuff was a great source of wealth to Norwich and other towns in the eastern counties. A special sort of woollen yarn took its name from Worstead in Norfolk, where it was made; it had a closer and harder twist than most woollen thread, and thus could be made up into cloth of special fineness, which was used for chasubles and other vestments, as is recorded in the inventories of York, Exeter, and other cathedrals.

Old English names.

Old English Names for Textiles.—A large number of names for different sorts of textiles occur in old English writings, many of them derived from the name of the place where the stuff was made or exported. *Buckram* was a woven cloth of much richness, highly prized, probably quite unlike what we now mean by the word. *Damask* or *damas* got its name from Damascus. *Fustian*, from Fostat (Old Cairo), was a cheaper stuff made of linen and cotton mixed. *Muslin*, from Mosul, was a fine cotton stuff. *Cloth of Tars* (Tarsus) is often mentioned, usually meaning a purple cloth. *Camoca* or *camak* (Arab. *kamkha*, from Chinese *kimkha*, "brocade") was another richly decorated Oriental stuff. *Cendal* or *sandal* and *syndonus* were fine silk stuffs. *Taffeta* was made of silk or linen of very thin substance. *Satin* (from Low Lat. *seta*) was a glossy silk stuff made like samite. *Velvet* (from It. *velluto*, "shaggy") had a silk weft woven so as to form a raised pile, the ends of which were cut or shaved off to one even level; hence it is also called in Italy *raso*. *Diaper*, "jasper-like" (Ital. *diaspro*), was not only used to denote a regular geometrical pattern, but in some cases means also a special sort of linen or silk. Phrases such as "silk of brydges" (Bruges), "silk dornex," from Dorneck in Flanders, and "sheets of raynes" (Rheims) often occur. A large number of other similar names are to be met with in mediæval writings.[7]

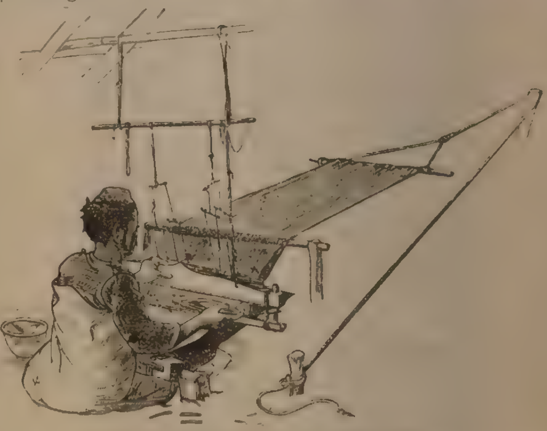

FIG. 8.—Indian hill loom, as still used.

Other mediæval and modern types.

Space will not allow a description of the textile work in each separate country. That of Italy and the East was by far the most important throughout the Middle Ages. Even Chinese textiles of gold and silk were imported into the west of Europe, and were sometimes used for ecclesiastical purposes. Mediæval vestments of Chinese stuff still exist, the shape and added borders of which show that they date from as early as the 14th century. These fabrics exactly resemble in design and workmanship some which are woven in China at the present day. A very interesting survival of the mediæval style of weaving exists in Sweden and other Scandinavian countries. Articles of dress, counterpanes, table-covers, and the like are woven by the peasantry in a simple, highly decorative way, with patterns which have altered little during the last three or four centuries. Though coarse in texture, many of these are of great artistic beauty; nothing but an occasional use of harsh colors shows any sign of decadence of style. Strong marks of Oriental influence are visible in these fine patterns, but the method of weaving is purely native,—probably very like what the edicts of Louis IX. call "tapisserie nostrez." Very beautiful fabrics are still produced in India, old designs being followed, and woven in the simplest form of loom. Fig. 8 shows an example of a modern Indian loom used by the hill weavers. In such looms the richest materials, such as gold and silk, and the most elaborate patterns are woven, often by travelling weavers who can set up their whole apparatus in a very short time.

---

[1] The process of making wire by drawing it through conical apertures in a steel plate is said to have been first invented at Nuremberg in the 14th century.

[2] The Museo Gregoriano (Vatican) contains examples from Etruscan tombs.

[3] Equal to quite £50 [$243] of modern money.

[4] Hence thin paper laid between the folds of these rich stuffs to protect them was called *tissue paper*.

[5] The celebrated cope in Pienza cathedral, which once belonged to Pius II. (Piccolomini), is a magnificent example of English needlework of the 15th century.

[6] Among Chaucer's pilgrims are included "A webbe, a dyer, and a tapisser," the first a low-loom weaver, the last a weaver of tapestry on the high loom.

[7] The most extraordinary spelling often occurs in lists of textiles in mediæval documents, especially in the case of foreign names. Thus we find in the Bury Wills (printed by the Camden Society) "fuschan in Appules" meaning Naples fustian, and many similar blunders.

CARPETS.

Carpets.

Carpet weaving was essentially an Oriental art, and was the natural product of a dry mudless country, where little furniture was used and the shoes were removed on entering a building. Till the 16th century carpets were almost unknown in France and England, except for royal personages and for the sanctuaries of cathedrals and important churches. In the latter case they were usually laid in front of the high altar, and thus carried on to the floor the richness of color which ornamented the walls and vault. Oriental carpets frequently occur in cathedral inventories among the other rich treasures of foreign or native make which adorned the building. They were first employed in England for domestic purposes by Queen Eleanor of Castile and her suite, in the latter part of the 13th century. In the palaces of Spain they were introduced much earlier, owing to the presence of the Moors in southern Spain. In many cases they were used for wall hangings, and the smaller ones to cover tables and other furniture, as is represented in many 15th-century Italian pictures. Though few examples of Oriental carpets exist earlier in date than the 15th century, yet the manufacture was carried on in the highest state of perfection centuries before. An example of the 14th century is preserved in a private collection at Vienna; it was originally made as a hanging for the Kaaba at Mecca.[1] These beautiful Oriental pile carpets are among the most perfect productions of the weaver's art, and till the 16th century were masterpieces of design and splendor of color. Usually they were woven of wool or of camels' or goats' hair, with a separate warp and weft of flax; but many magnificent carpets were also made of silk mixed with gold thread. This extravagance of luxury produced an effect, at least as regards the use of silk, but little superior to that of fine wool or camels' hair, as the special beauty of the silken gloss is seen on the sides, not on the ends of the silk thread. Pile carpets are woven in a very different way from ordinary textiles: short tufts of wool or silk are knotted on the warp so that the ends of the threads which form the pattern project, and these are cut down by shears to a uniform surface, thus forming a sort of textile mosaic. Each row is firmly fixed by a shoot of linen weft-thread thrown across the web, and then carefully beaten down with the batten.

Various classes of ornament occur in these magnificent Oriental carpets; one variety has stiff geometrical patterns, the motives of which appear to be taken from mosaics or tiles. Another and still more beautiful sort, manufactured especially at Ispahan (see Fig. 9), has elaborate flowing designs of flower forms, sometimes mixed with figures of cheetahs, lions, antelopes, and birds, in a few cases combined with human figures. Mr. W. Morris, in his valuable lecture on textile fabrics (London, 1884), traces three stages of design,—first, a pure flowing style, closely resembling the early stucco mural reliefs of Cairo; secondly, a similar style blended with animal forms; and thirdly, a purely floral style, flowing in its lines and very fantastic and ingenious in its patterns; this last he thinks belongs to about the time of Shah Abbas, and lasted from about 1550 to 1650,—the culminating period of Oriental art.[2] Since then there has been a distinct degradation of style, though in many cases older

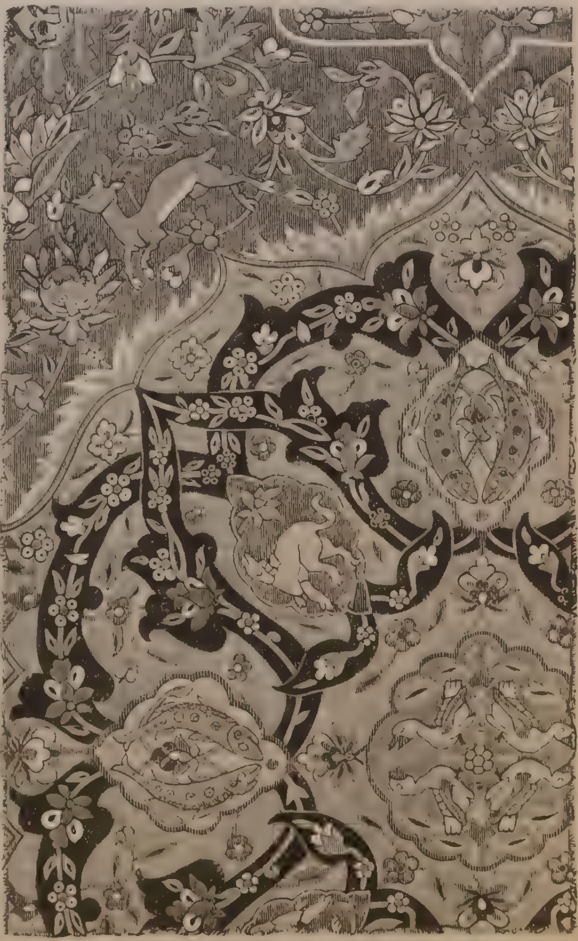

FIG. 9.—Persian pile carpet of the 15th century, woven of goats' hair and silk. (South Kensington Museum.)

---

[1] See Karabacek, *Die persische Nadelmalerei Susandschird* and *Oestr. Monatsch. f. d. Orient*, 1884, p. 49, with cut.

[2] A valuable help towards establishing the dates of carpet patterns is given by many mediæval Italian pictures, in which Oriental carpets are often represented with wonderful minuteness and appreciation.

patterns have been worked from and very perfect work produced. At the present day the influence of European taste is rapidly destroying this survival of the best class of design, and especially is introducing the most harsh and discordant coloring in place of the glorious rich hues of the earlier Oriental weavers.

Though no existing specimens can be pointed out, it appears probable that the "tapisserie Saracenois" of Louis IX.'s edicts (1226–1270) refers to pile carpets made by French weavers after the Oriental fashion.[1] The same edicts for the regulation of the textile industry mention two other classes of manufacture, "tapisserie à la haute lisse," *i.e.*, what we call tapestry, and "tapisserie nostrez," "native stuff," probably resembling the coarse but effective patterned fabrics for aprons and dresses which are still woven by the peasantry near Rome, in the Abruzzi mountains, and elsewhere in Italy and in Scandinavia.

TAPESTRY.

Tapestry.

The making of tapestry (Gk. τάπης), like the weaving of pile carpets, differs from ordinary fabric in that no visible weft is thrown completely across the loom, but the design is formed by short stitches knotted across the warp with a wooden needle called a *broach*. It is a sort of link between textile work and embroidery, from which it differs in having its stitches applied, not to a finished web, but to the stretched strings of a warp.[2] It is made on a high loom, and the whole process, though requiring much skill, is mechanically of the simplest kind. It is very probable that many of the woven hangings used in ancient Egypt, Greece, and other countries were true tapestry; but little is known on this point. Till after the 12th century, in northern Europe, embroidery seems to have served the place of tapestry, as, for example, in the wrongly named Bayeux tapestry (see vol. viii. p. 149); while in the south of Europe and in Oriental countries its place was supplied by the rich silken textiles and pile carpets mentioned above.

Flemish.

In the 14th century tapestry began to be largely made, especially in Flanders, where the craft of weaving became very important at an early time. The designs on the very few existing samples of 14th-century tapestry closely resemble those of contemporary wall painting. A characteristic early specimen in the Louvre has rows of medallions, each containing a scene from the life of St. Martin, with two or three figures treated in a very simply decorative way. The spaces between the circles are filled up with a stiff geometrical ornament. To the end of the 14th century belongs the magnificent tapestry in Angers cathedral, on which are represented scenes from the Apocalypse; these were made at Arras, the chief seat of the tapestry manufacture, both for quantity and quality. Hence the name *arras* (Italian *arazzi*) came to mean any sort of tapestry, wherever it was made. Another magnificent series of arras work is preserved in Rheims cathedral, with designs from the history of Clovis; these date from the middle of the 15th century. In the 14th century Flanders produced enormous quantities of woven stuffs. At that time twenty-seven streets were occupied by the weavers of Ghent; in 1382 there were 50,000 weavers in Louvain; and at Ypres there is said to have been a still larger number. From about 1450 to 1500 was the golden age for tapestry, especially in Bruges and Arras, where large quantities of the most magnificent historical pieces were woven from designs supplied by painters of the Van Eyck school. The Flemish tapestries of that time are perfect models of textile art, rich in color, strong in decorative effect, graceful in drawing and composition, and arranged with consummate skill to suit the exigencies of the loom and the æsthetic requirements of wall decoration. A very beautiful example of this class exists at Hampton Court, hung in the dark under the gallery in the great Hall,—a striking contrast to the clever but artistically degraded tapestries of half a century later, which hang round the main walls of the hall. Other fine examples exist in the Cluny, Bern, and other museums, and especially in Madrid[3]—in the royal collection and in that of the duke of Alva—and elsewhere in Spain. Though very rich and varied in effect, the tapestry of the best period usually is woven with not more than twenty different tints of wool,—half tints and gradations being got by hatching one color into another. In the 16th century about sixty colors were principally employed in the still fine but

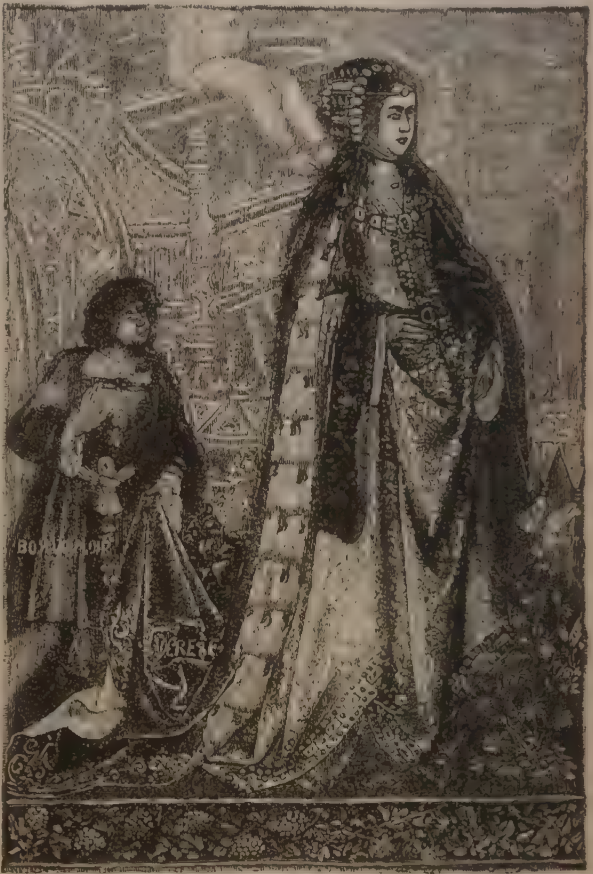

FIG. 10.—Figure of Lucretia from the Triumph of Chastity, woven at Brussels about 1507. Her dress is an Italian velvet, similar in style to that shown in Fig. 6.

---

[1] *Tapisserie* in French means all sorts of patterned stuffs.

[2] In tapestry the weft stitches are put in loosely and carefully pressed home, so that the warp strings are completely hidden.

[3] See Riaño, *Tapestry of the Palace at Madrid*, London, 1875; of all countries Spain is the richest in tapestry of the 15th and 16th centuries. The royal collection contains 2000 large pieces. Rich stores also belong to the principal cathedrals, such as Toledo, which on the feast of Corpus Christi is completely hung round with tapestry outside as well as inside. In the 17th century tapestry looms were worked in Spain under royal patronage. One of Velazquez's finest pictures in the Madrid Gallery (Las Hilanderas) represents the visit of some court ladies to a tapestry fabrique, in which women are working the looms.

rapidly deteriorating tapestry of that period; and in the laborious but artistically worthless productions of the Gobelin factory more than 14,000 differently tinted wools are now used.

In the 16th century the art began to decline; very slight symptoms of decadence are visible in the beautiful tapestries with Petrarch's *Triumphs* in the South Kensington Museum,—most gorgeous pieces of textile art, of the richest decorative effect. These were worked very soon after 1500 (see Fig. 10). The influence of Raphael and his school succeeded that of the 15th century Flemish painters, and was utterly destructive of true art value in tapestry. Raphael's cartoons, fine as they are in composition, are designed without the least reference to textile requirements, and are merely large pictures, which the weavers had to copy as best they might. This new style, which reduced the art to a feeble copyism of painting, gave the death-blow to the production of really fine tapestry. Brussels became the chief place for the manufacture after the taking of Arras by Louis XI. in 1477, and its weavers with wonderful skill imitated any sort of painting that was put before them. Cartoons were drawn by several of Raphael's pupils, such as Giulio Romano and Giovanni da Udine, and by Mabuse, Michiel Coxcie, Bernard van Orley, and other Italianized Flemish painters.

French.

In 1539 Francis I. founded a factory for tapestry at Fontainebleau, and soon after other high looms were set up in Paris, examples from which still exist and show a rapid degradation of style. In 1603 a new factory was started in Paris under royal patronage, in the workshop of a family of dyers named Gobelin, after whom the new factory was named (see GOBELIN). The Gobelin looms were first worked by weavers from Flanders, who soon taught the mysteries of the craft to a number of French workmen. Cartoons were supplied by Simon Vouet and other distinguished French painters. In the reign of Louis XIV. a great impulse was given to the factory, and from 1667 the whole establishment became the property of the crown. Louis XIV.'s minister, Colbert, did much to encourage this and other industries. Charles Le Brun the painter was made director of the works, and a number of artists prepared the cartoons under his supervision. In the 18th century Coypel, Jouvenet, Boucher, Watteau, and many other popular painters made designs, often of great size and elaboration, for the Gobelin looms, but all in the very worst possible taste; these include large series of sacred, mythological, and historical subjects, landscapes, sea-pieces, and even portraits,—the last being perhaps the most ridiculous misuse of the textile art that could possibly be invented. Other tapestry looms were worked in the 18th century at Aubusson, Felletin, and other places in France.

English.

High-warp looms appear to have been worked in England in the 15th century, though by far the greater part of the rich stores of tapestry in this country came from Flanders. One very beautiful example of English work of this time exists in St. Mary's hall at Coventry; it represents the marriage of Henry VI. Part of another series with the marriage of Henry VII. is preserved in a house in Cornwall. In the latter part of the 15th and the first half of the 16th century enormous sums were spent by the rich in England on Flemish tapestry. Cardinal Wolsey's private accounts and inventories, which still exist,[1] give an astonishing picture of the wealth which he lavished on the adornment of his palace at Hampton Court. In 1522 he bought 132 large pieces of Brussels tapestry, woven with Scriptural subjects, and mostly made to order, so as to fit exactly the various wall spaces. He also bought large quantities of costly Oriental carpets. In the inventories are enumerated "foot carpets," "table carpets," and "window carpets," "hanging peces," "borders with arms," and "window peces," the last being strips of tapestry woven in narrow lengths to fit the sills and jambs of windows. Among the "wall peces," in addition to the numerous sacred subjects, are mentioned mythological scenes, romances, historical pieces, and "hangings of verdures," the last being decorative work in which trees and foliage formed the main design, with accessory figures of hunting, hawking, and the like. The catalogue of Wolsey's linen napery is no less sumptuous and abundant; he possessed an immense quantity of finest linen for sheets and "board-cloths" (table-cloths), mostly patterned with "damaske diaper" or "paned losinge-wise." This example of the wealth of textile work possessed by one rich prelate will give some notion of what England and other countries possessed in the 16th century.

In the reign of James I. tapestry looms were set up at Mortlake, and the industry was carried on during the following reign under the direction of the painter Francis Crane. Charles I. introduced skilled weavers from Oudenarde in Belgium, and the whole existing series of cartoons by Raphael were copied on the Mortlake looms.[2] Most of the Mortlake tapestry has distinct marks, such as the shield of St. George with F. C. (F. Crane). Some pieces are inscribed "Car. Re. Reg. Mortl." (Carolus rex regnans). Though closed during the Commonwealth, the Mortlake fabrique was again worked after the Restoration until the death of Crane in 1703. In the 18th century tapestry was woven on a small scale in Soho and at Fulham, and within recent years a new royal fabrique has been established at Windsor, where very costly and skilful weaving in the pictorial Gobelin style is carried on. The only modern tapestry which has any of the merits of the best old productions is that made on a small scale by Mr. William Morris at Merton Abbey (Surrey), where work of the highest beauty has been produced. Unfortunately, however, the modern taste for feeble imitations of oil paintings has as yet shown little appreciation of this revival of the true textile art.

Italian.

As in England, by far the greater part of the tapestry used in Italy was a Flemish import. But in the 16th century, under the patronage of the dukes of Ferrara, tapestry loomes were set up in Ferrara; these were, however, worked by Flemish weavers, and closely resemble contemporary tapestry woven at Brussels. Other fabriques were established in Florence by the Medici princes, and continued to be worked till the end of the 17th century. Factories for tapestry existed also at Venice, Turin, and other northern cities, but the industry was purely an exotic, and never attained to any great importance. Since the pontificate of Clement XI., in 1702,[3] a papal factory for tapestry has existed in Rome, and is still carried on in the Vatican. The papal looms have produced a large number of most costly and elaborate copies of celebrated paintings, executed with wonderful skill, but utterly worthless as works of art.

Collections.

The South Kensington Museum possesses the best and most illustrative collection of woven fabrics of various dates. The church of St. Mary at Dantzic has a magnificent collection of early textiles, mostly used for vestments; these are well illustrated by Hinz, *Die Schatzkammer der Marien-Kirche zu Dantzig*, 1870. Fine examples of early tapestry exist in the cathedrals of Rheims, Bruges, Tourney, Angers, Beauvais, Aix, Sens, and in the church of St. Rémy at Rheims. Other fine collections are preserved in the Louvre, the Cluny Museum at Chartres, Amiens, Dijon, Orleans, Auxerre, Nancy, Bern, Brussels, Munich, Berlin, Dresden, Vienna, and Nuremberg.[4] In Italy the richest collections (mostly of later tapestry) are those of the Vatican, the Pitti, the Bargello Palazzo del Tè at Mantua, Turin (royal palace), Milan (royal palace), Como (cathedral), and the museum of Naples.

---

[1] See Law, *Hampton Court Palace*, London, 1885.

[2] See RAPHAEL, vol. xx. p. 292.

[3] An earlier fabrique was started in 1630 by Urban VIII., but it soon ceased to be worked.

[4] The large collection in the Gobelin Museum was burnt in 1871.

The Spanish collections have been already mentioned. In England, besides the South Kensington Museum, fine tapestries exist in the palaces of Windsor and Hampton Court. Those formerly in the House of Lords were destroyed in the fire of 1834. St. Mary's Hall at Coventry contains the finest examples of the 15th century.

Literature.—By far the best work for its well-chosen colored illustrations is that of Fischbach, *Textile Fabrics*, English ed., 1883; see also Dupont-Auberville, *L'ornement des tissus*, Paris, 1875–77; Michel, *Recherches sur la fabrication des étoffes*, Paris, 1852 (a very valuable work); Jubinal, *Anciennes tapisseries*, Paris, 1858–59; De Ronchaud, *Le péplos d'Athèné*, Paris, 1872; Id., *La tapisserie*, Paris, 1885; Müntz, *La tapisserie dans l'antiquité*, Paris, 1878; Lessing, *Modèles de tapis Orientaux*, Paris, 1879; Id., *Ancient Oriental Carpets*, London, 1879; Vincent Robinson, *Oriental Carpets*, London, 1882 (the illustrations are better than the text); Lady Alford, *Needlework as Art*, London, 1886 (deals partly with textiles). Though few works treat of the general history of textiles, a very large number exist about tapestry weaving. The chief are —Depping, *Règlements sur les arts . . . au XIII^{me} siècle*, Paris, 1837; De Montault, *Tapisserie de la cath. d'Angers*, Paris, 1863; De Farcy on the same subject, 1875; Barraud, *Tap. de la cath. de Beauvais*, Beauvais, 1853; Rock, *Textile Fabrics, S.K.M.*, London, 1870; Bock, *Cat. des tissus*, etc., *au Musée German.*, Nuremberg, 1869; Kinkel, *Rogier van der Weyden . . . et les tapisseries de Berne*, Zurich, 1867; Givelet, *Toiles brodées de Reims*, Rheims, 1883; Louis Paris, *Tap. de la ville de Reims*, Rheims, 1843; Loriquet, *Tap. de Notre Dame de Reims*, Rheims, 1876; Pinchart, *Tap. dans les Pays-Bas*, and other works, Brussels, 1859–64; Dehaisnes, *Tap. d'Arras avant le XV^{me} siècle*, Paris, 1879; Proyart, *Recherches sur les tap. d'Arras*, Arras, 1863; Voisin, *Tap. de la cath. de Tournay*, Tournay, 1863; Van Drival, *Tap. d'Arras*; Arras, 1864; Gorse, *Tap. du château de Pau*, Paris, 1881; De la Fons-Melicoq, *Hautlisseurs des XIV^{me} au XVI^{me} siècles*, Paris, 1870; Santerre, *Tap. de Beauvais*, Clermont, 1842; Deville, *Statuts*, etc., *relatifs à la corp. des tap. de 1258 à 1275*, Paris, 1875; Darcel, *Gaz. d. b.-arts*, xiv. pp. 185, 273, and 414; Van deGraft, *De Tapijt-Fabrieken de XVI. en XVII. Eeuw*, Middelburg, 1869. On Italian tapestry, see de Montault, *Tap. de haute lisse à Rome*, Arras, 1879; Conti, *L'arte degli arazzi in Firenze*, Florence, 1875; Campori, *L'arazzeria Estense*, Modena, 1876; Braghirolli, *Arazzi in Mantova*, Mantua, 1879; Farabulini, *L'arte degli arazzi*, Rome, 1884; Gentili, *L'art des tapis*, Rome, 1878; and Müntz, *Tap. Italiennes*, Paris, 1880. On French and other late tapestry, see Darcel and Guichard, *Les tap. décoratives*, Paris, 1881; Lacordaire, *Hist. de tapisserie*, Paris, 1855; Guillaumot, *L'Origine . . . des Gobelins*, Paris, 1860; Perathon, *Tap. d'Aubusson, de Felletin, et de Bellegarde*, Paris, 1857; Roy-Pierrefitte, *Les tap. de Felletin*, Limoges, 1855; Durieux, *Tap. de Cambrai*, Cambrai, 1879; About and Bauer, *Tap. après les cartons de Raphael*, Paris, 1875; Houdoy, *Tap. de la fabrication Lilloise*, Lille, 1871; Vergnaud-Romagnesi, *Tap. au Musée d'Orléans*, Orleans, 1859; De St. Genois, *Tap. d'Oudenarde*, Paris, 1864; Talcot, *Fabric. des tissus*, Paris, 1852; Guiffrey, *Hist. de la tapisserie*, Tours, 1886; Pine, *Tapestry of the House of Lords*, London, 1739; and De Champeaux, *Tapestry*, S.K.M. handbook, London, 1878; Ashenhurst, *Treatise on Weaving*, London, 1886.

(J. H. M.)

TEZA, or TÁZÁ. See MOROCCO, vol. xvi. p. 860.

THACKERAY, WILLIAM MAKEPEACE (1811–1863), one of the greatest of English authors and novelists, son of Richmond Thackeray (Mrs. Richmond Thackeray was born Miss Becher), and grandson of W. R. Thackeray of Hadley, Middlesex, was born at Calcutta on July 18, 1811. Both his father and grandfather had been Indian civil servants. His mother, who was only nineteen at the date of his birth, was left a widow in 1816, and afterwards married Major Henry Carmichael Smyth. Thackeray himself was sent home to England from India as a child, and went to Charterhouse, since his time removed to Godalming from its ancient site near Smithfield. Anthony Trollope, in his book on Thackeray in the *English Men of Letters* series, quotes a letter written to him about Thackeray's school-days by Mr. G. S. Venables. "He came to school young," Mr. Venables wrote, "a pretty, gentle, and rather timid boy." This accords with the fact that all through Thackeray's writings the student may find traces of the sensitiveness which often belongs to the creative mind, and which, in the boy who does not understand its meaning and its possible power is apt to assume the guise of a shy disposition. To this very matter Mr. Venables tersely refers in a later passage of the letter quoted by Trollope: "When I knew him better, in later years, I thought I could recognize the sensitive nature which he had as a boy." Another illustration is found in the statement, which will be recognized as exact by all readers of Thackeray, that "his change of retrospective feeling about his school-days was very characteristic. In his earlier books he always spoke of the Charterhouse as Slaughter House and Smithfield. As he became famous and prosperous his memory softened, and Slaughter House was changed into Grey Friars, where Colonel Newcombe ended his life." Even in the earlier references the bitterness which has often been so falsely read into Thackeray is not to be found. In "Mr. and Mrs. Frank Berry" (*Men's Wives*) there is a description of a Slaughter-House fight, following on an incident almost identical with that used in *Vanity Fair* for the fight between Dobbin and Cuff. In both cases the brutality of school life, as it then was, is very fully recognized and described, but not to the exclusion of the chivalry which goes alongside with it. In the first chapter of "Mr. and Mrs. Frank Berry," Berry himself and Old Hawkins both have a touch of the heroic. In the story which forms part of *Men's Wives* the bully whom Berry gallantly challenges is beaten, and one hears no more of him. In *Vanity Fair* Cuff the swaggerer is beaten in a similar way, but regains his popularity by one well-timed stroke of magnanimity, and afterwards shows the truest kindness to his conqueror.

In February, 1829, Thackeray went to Trinity College, Cambridge, and in that year contributed some engaging lines on *Timbuctoo*, the subject for the prize poem, to a little university paper called *The Snob*, the title of which he afterwards utilized in the famous *Snob Papers*. The first stanza has become tolerably well known, but is worth quoting as an early instance of the direct comic force afterwards employed by the author in verse and prose burlesques:

> In Africa—a quarter of the world—
> Men's skins are black; their hair is crisp and curled;
> And somewhere there, unknown to public view,
> A mighty city lies, called Timbuctoo.

One other passage at least in *The Snob*, in the form of a skit on a paragraph of fashionable intelligence, seems to bear traces of Thackeray's handiwork. At Cambridge James Spedding, Monckton Milnes (Lord Houghton), Edward Fitzgerald, W. H. Thompson (afterwards master of Trinity), and other distinguished persons were among his friends. In 1830 he left Cambridge without taking a degree, and went to Weimar and to Paris. His visit to Weimar bore fruit in the sketches of life at a small German court which appear in *Fitz-Boodle's Confessions* and in *Vanity Fair*. In 1832 he came of age, and inherited a sum which Trollope's book describes as amounting to about five hundred a year. The money was soon lost,—some in an Indian bank, some in two newspapers which in *Lovel the Widower* are referred to under one name as *The Museum*, in connection with which our friends Honeyman and Sherrick of *The Newcomes* are briefly brought in. His first regular literary employment after the loss of his patrimony was on *Fraser's Magazine*, in which in 1837–38 appeared *The History of Mr. Samuel Titmarsh and the Great Hoggarty Diamond*, a work filled with instances of the wit, humor, satire, pathos, which found a more ordered if not a fresher expression in his later and longer works. For freshness, indeed, and for a fine perception which enables the author to perform among other feats that of keeping up throughout the story the curious simplicity of its supposed narrator's character, the *Great Hoggarty Diamond* can scarce be surpassed. The characters from Lady Drum, Lady Fanny, Lady Jane, and Edmund Preston down to Brough, his daughter, Mrs. Roundhand, Gus Hoskins, and, by no means least, Samuel Titmarsh's pious aunt with her store of "Rosolio," are living; the book is crammed with honest fun; and, for pure pathos, the death of the child, and the meeting of the husband and wife over the empty cradle (a scene illustrated by the author himself with that suggestion of truth which no shortcoming in drawing could spoil), stands, if not alone in its own line, at least in the company of very few such scenes in English fiction. The *Great Hoggarty Diamond*, oddly enough, met with the fate that afterwards befell one of Lever's best stories which appeared in a periodical week by work,—it had to be cut short at the bidding of the editor. In the same year in which it appeared Thackeray married Isabella, daughter of Colonel Matthew Shawe. Of the daughters born of the marriage, one, Mrs. Richmond Ritchie, has earned distinction as a novelist. Mrs. Thackeray, to quote Trollope, "became ill and her mind failed her," and Thackeray thereupon "became as it were a widower till the end of his days." In 1840 came out *The Paris Sketch Book*. Much of it had been written and published at an earlier date, and in the earlier writings there are some very curious divagations in criticism. The book contains also a striking story of card-sharping, afterwards worked up and put into Altamont's mouth in *Pendennis*, and a very powerful sketch of a gambler's death and obsequies. Three years before, in 1837, Thackeray had begun in *Fraser*, the *Yellowplush Papers*, with their strange touches of humor, satire, tragedy (in one scene, the closing one of the history of Mr. Deuceace), and their sublimation of fantastic bad spelling (M'Arony for macaroni is one of the typical touches of this); and this was followed by *Catherine*, a strong story, and too disagreeable perhaps for its purpose, founded closely on the actual career of a criminal named Catherine Hayes, and intended to counteract the then growing practice of making ruffians and harlots prominent characters in fiction. There soon followed *Fitz-Boodle's Confessions and Professions*, including the series *Men's Wives*, already referred to; and, slightly before these, *The Shabby Genteel Story*, a work interrupted by Thackeray's domestic affliction and afterwards republished as an introduction to *The Adventures of Philip*, which took up the course of the original story many years after the supposed date of its catastrophe. In 1843, and for some ten years onwards according to Trollope, Thackeray was writing for *Punch*, and the list of his contributions included among many others the celebrated *Snob Papers* and the *Ballads of Policeman X*. In 1843 also came out the *Irish Sketch Book*, and in 1844 the account of the journey *From Cornhill to Grand Cairo*, in which was published the excellent poem of *The White Squall*. In 1844 there began in *Fraser* the *Memoirs of Barry Lyndon*, called in the magazine *The Luck of Barry Lyndon, a Romance of the Last Century*. *Barry Lyndon* has, with a very great difference in treatment, some resemblance to Smollett's *Count Fathom*; the hero, that is to say, is or becomes a most intolerable scoundrel, who is magnificently unconscious of his own iniquity. The age and pressure of the time depicted are caught with amazing verisimilitude, and in the boyish career of Barry Lyndon there are fine touches of a wild chivalry, simplicity, and generosity, which mingle naturally with the worse qualities that, under the influence of abominable training, afterwards corrupt his whole mind and career. The man is so infatuated with and so blind to his own roguery, he has so much dash and daring, and is on occasions so infamously treated, that it is not easy to look upon him as an entirely detestable villain until, towards the end of his course, he becomes wholly lost in brutish debauchery and cruelty. His latter career is founded on that of Andrew Robinson Stoney Bowes, who married the widow of John, ninth earl of Strathmore. There is also no doubt a touch of Casanova in Barry Lyndon's character. Besides the contributions to *Punch* specially referred to, there should be noticed *Punch's Prize Novelists*, containing some brilliant parodies of Edward Lytton Bulwer, Lever, Mr. D'Israeli (in *Codlingsby*, perhaps the most perfect of the series), and others. Among minor but admirable works of the same period are found *A Legend of the Rhine* (a burlesque of the great Dumas's *Othon l'Archer*), brought out in a periodical of George Cruikshank's, *Cox's Diary* (on which has been founded a well-known Dutch comedy, *Janus Tulp*), and the *Fatal Boots*. This is the most fitting moment for mentioning also *Rebecca and Rowena*, which towers, not only over Thackeray's other burlesques, excellent as they are, but over every other burlesque of the kind ever written. Its taste, its wit, its pathos, its humor, are unmatchable; and it contains some of the best songs of a particular kind ever written—songs worthy indeed to rank with Peacock's best. In 1846 was published by Messrs. Bradbury and Evans, the first of twenty-four numbers of *Vanity Fair*, the work which first placed Thackeray in his proper position before the public as a novelist and writer of the first rank. It was completed in 1848, when Thackeray was thirty-seven years old; and in the same year Abraham Hayward paid a tribute to the author's powers in the *Edinburgh Review*. It is probable that on *Vanity Fair* has been largely based the foolish cry, now heard less and less frequently, about Thackeray's cynicism, a cry which he himself, with his keen knowledge of men, foresaw and provided against, amply enough as one might have thought, at the end of the eighth chapter, in a passage which is perhaps the best commentary ever written on the author's method. He has explained how he wishes to describe men and women as they actually are, good, bad, and indifferent, and to claim a privilege—

> "Occasionally to step down from the platform, and talk about them; if they are good and kindly, to love and shake them by the hand; if they are silly, to laugh at them confidentially in the reader's sleeve; if they are wicked and heartless, to abuse them in the strongest terms politeness admits of. Otherwise you might fancy it was I who was sneering at the practice of devotion, which Miss Sharp finds so ridiculous; that it was I who laughed good-humoredly at the railing old Silenus of a baronet—whereas the laughter comes from one who has no reverence except for prosperity, and no eye for anything beyond success. Such people there are living and flourishing in the world—Faithless, Hopeless, Charityless: let us have at them, dear friends, with might and main. Some there are, and very successful too, mere quacks and fools: and it was to combat and expose such as those, no doubt, that laughter was made."

As to another accusation which was brought against the book when it first came out, that the colors were laid on too thick, in the sense that the villains were too villainous, the good people too goody-goody, the best and completest answer to that can be found by any one who chooses to read the work with care. Osborne is, and is meant to be, a poor enough creature, but he is an eminently human being, and one whose poorness of character is developed as he allows bad influences to tell upon his vanity and folly. The good in him is fully recognized, and comes out in the beautiful passage describing his farewell to Amelia on the eve of Waterloo, in which passage may be also found a sufficient enough answer to the statement that Amelia is absolutely insipid and uninteresting. So with the companion picture of Rawdon Crawley's farewell to Becky: who that reads it can resist sympathy, in spite of Rawdon's vices and shady shifts for a living, with his simple bravery and devotion to his wife? As for Becky, a character that has since been imitated a host of times, there is certainly not much to be said in her defence. We know of her, to be sure, that she thought she would have found it easy to be good if she had been rich, and we know also what happened when Rawdon, released without her knowledge from a spunging-house, surprised her alone with and singing to Lord Steyne in the house in May Fair. After a gross insult from Steyne, "Rawdon Crawley, springing out, seized him by the neckcloth, until Steyne, almost strangled, writhed and bent under his arm. 'You lie, you dog,' said Rawdon; 'you lie, you coward and villain!' And he struck the peer twice over the face with his open hand, and flung him bleeding to the ground. It was all done before Rebecca could interpose. She stood there trembling before him. She admired her husband, strong, brave, and victorious." This admiration is, as Thackeray himself thought it, the capital touch in a scene which is as powerful as any Thackeray ever wrote—as powerful, indeed, as any in English fiction. Its full merit, it may be noted in passing, has been curiously accented by an imitation of it in M. Daudet's *Fromont Jeune et Risler Aîné.* As to the extent of the miserable Becky's guilt in the Steyne matter, on that Thackeray leaves it practically open to the reader to form what conclusion he will. There is, it should be added, a distinct touch of good in Becky's conduct to Amelia at Ostend in the last chapter of the book, and those who think that too little punishment is meted out to the brilliant adventuress in the end may remember this to her credit. It is supreme art in the treatment of her character that makes the reader understand and feel her attractiveness, though he knows her extraordinarily evil qualities; and in this no writer subsequent to Thackeray who has tried to depict one of the genus Becky Sharp has even faintly succeeded. Among the minor characters there is not one—and this is not always the case even with Thackeray's chief figures—who is incompletely or inconsistently depicted; and no one who wishes to fully understand and appreciate the book can afford to miss a word of it.

Vanity Fair was followed by *Pendennis*, *Esmond*, and *The Newcomes*, which appeared respectively in 1850, 1852, and 1854. It might be more easy to pick holes critically in *Pendennis* than in *Vanity Fair*. Pendennis himself, after his boyish passion and university escapades, has disagreeable touches of flabbiness and worldliness; and the important episode of his relations with Fanny Bolton, which Thackeray could never have treated otherwise than delicately, is so lightly and tersely handled that it is a little vague even to those who read between the lines; the final announcement that those relations have been innocent can scarcely be said to be led up to, and one can hardly see why it should have been so long delayed. This does not of course affect the value of the book as a picture of middle and upper class life of the time, the time when Vauxhall still existed, and the haunt for suppers and songs which Thackeray in this book called the Back Kitchen, and it is a picture filled with striking figures. In some of these, notably in that of Foker, Thackeray went, it is supposed, very close to actual life for his material, and in that particular case with a most agreeable result. As for the two *umbræ* of the marquis of Steyne, it is difficult to believe that they were intended as caricatures from two well-known persons. If they were, for once Thackeray's hand forgot its cunning. Here, as in *Vanity Fair*, the heroism has been found a little insipid; and there may be good ground for finding Laura Pendennis dull, though she has a spirit of her own. In later books she becomes, what Thackeray's people very seldom are, a tiresome as well as an uninviting person. Costigan is unique, and so is Major Pendennis, a type which, allowing for differences of period and manners, will exist as long as society does, and which has been seized and depicted by Thackeray as by no other novelist. His two encounters, from both of which he comes out victorious, one with Costigan in the first, the other with Morgan in the second volume, are admirable touches of genius. In opposition to the worldliness of the major, with which Pendennis does not escape being tainted, we have Warrington, whose nobility of nature has come unscathed through a severe trial, and who, a thorough gentleman if a rough one, is really the guardian of Pendennis's career. There is, it should be noted, a characteristic and acknowledged confusion in the plot of Pendennis, which will not spoil any intelligent reader's pleasure.

Probably most readers of *The Newcomes* (1854) to whom the book is mentioned think first of the grand, chivalrous, and simple figure of Colonel Newcome, who stands out in the relief of almost ideal beauty of character against the crowd of more or less imperfect and more or less base personages who move through the novel. At the same time, to say, as has been said, that this book "is full of satire from the first to the last page," is to convey an impression which is by no means just. There is plenty of kindliness in the treatment of the young men who, like Clive Newcome himself and Lord Kew, possess no very shining virtue beyond that of being honorable gentlemen; in the character of J. J. Ridley, there is much tenderness and pathos; and no one can help liking the Bohemian F. B., and looking tolerantly on his failings. It may be that both the fiendish temper of Mrs. Mackenzie and the sufferings she inflicts on the Colonel are too closely insisted on; but it must be remembered that this heightens the singular pathos of the closing scenes of the Colonel's life. It has seemed convenient to take *The Newcomes* after *Pendennis*, because Pendennis and his wife reappear in this book as in the *Adventures of Philip;* but *Esmond* (1852) was written and published before *The Newcomes.* To some students *Esmond* seems and will seem Thackeray's capital work. It has not been rivalled, and only a few times approached by Mr. Besant, as a romance reproducing with unfailing interest and accuracy the figures, manners, and phrases of a past time, and it is full of beautiful touches of character. But Beatrix, upon whom so much hinges, is an unpleasing character, although one understands fully why men were captivated by her insolent beauty and brilliancy; and there is some truth in Thackeray's own saying, that, "Esmond was a prig." Apart from this, the story is, like the illusion of a past time in the narrative, so complete in all its details, so harmoniously worked out, that there is little room for criticism. As to Esmond's marriage with the lady whom he has served and loved as a boy, that is a matter for individual judgment. Beatrix, it has been indicated above, is wonderfully drawn; and not the least wonderful thing about her is her reappearance as the jaded, battered, worldly, not altogether unkindly, Baroness in *The Virginians.* It was just what Beatrix must have come to, and the degradation is handled with the lightest and finest touch.

In 1851 Thackeray had written *The English Humorists of the Eighteenth Century*, delivered as a series of lectures at Willis's Rooms in the same year, and re-delivered in the United States in 1852 and 1853, as was afterwards the series called *The Four Georges.* Both sets were written for the purposes of lecturing. In 1857 Thackeray stood unsuccessfully as a parliamentary candidate for Oxford against Mr. Cardwell, and in the same year appeared the first number of *The Virginians*, a sequel to *Esmond.* This is a most unequal work,—inferior, as sequels are apt to be, to *Esmond* as an historical romance, less compact and coherent, prone to divagation and desultoriness, yet charming enough in its lifelikeness, in the wit and wisdom of its reflections, and, as has been said, in its portrait of Beatrix grown old. The last number of *The Virginians* came out in 1859, and in the same year Thackeray undertook the editorship of the *Cornhill Magazine.* This was a task which, as readers of his *Roundabout* paper "Thorns in the Cushion" will remember, the kindliness and sensitiveness of his disposition made irksome to him, and he resigned the editorship in April, 1862, though he continued to write for the magazine until he died. In the *Cornhill* appeared from his pen *Lovel the Widower*, previously written, with different names for some of the personages, in dramatic form; *The Adventures of Philip*; the *Roundabout Papers*; and the story, unhappily never finished, called *Denis Duval.* *Lovel the Widower*, changed from the dramatic to the narrative form, remains a piece of high comedy in which the characters are indicated rather than fully worked out, with a bold and practiced touch. It contains some references to Thackeray's early and unfortunate newspaper speculations, and it was provided by the author with illustrations which as in others of his books have a value which is entirely their own in furnishing, as it were, a far completer commentary on the letterpress than could have been given by any draughtsman, however perspicacious and finished, who approached the pictorial representation of the characters from the outside. To the general statement thus indicated an exception should be made in the case of Doyle's illustrations to *The Newcomes* and to *Rebecca and Rowena.* On the other hand, not even Doyle could have matched the fun and spirit of Thackeray's own illustrations to another burlesque story, one of his best, *The Rose and the Ring.* The *Roundabout Papers*, a small storehouse of some of Thackeray's best qualities as an essayist, came out in the *Cornhill Magazine* simultaneously with *Lovel the Widower* and with *The Adventures of Philip.* Among them is one differing in form from the rest, called *The Notch on the Axe—a Story à la Mode.* It is an almost perfect specimen of the author's genius for burlesque story-telling; but it contains an odd instance, which a careful reader will not fail to discover, of the odd habit of inaccuracy of which Thackeray himself was conscious. *The Adventures of Philip* is, as has been before said, in the nature of a sequel to or a completion of *A Shabby Genteel Story.* As with the other direct sequel, it is a work of great inequality. It contains scenes of humor, pathos, satire, which rank with Thackeray's best work; some old friends from others of the novels make brief but pleasant reappearances in its pages; there are fine sketches of journalistic, artistic, and diplomatic life, and the scene from the last-named in Paris is inimitable. The Little Sister is altogether delightful; the Twysden family are terribly true and vastly diverting; the minor characters, among whom old Ridley, J. J.'s father, should be mentioned, are wonderfully hit off; nor did Thackeray ever write a better scene than that of the quarrel between Bunch, Baynes, and M'Whirter in the Paris pension. Philip himself is impossible; one cannot say that the character is ill-drawn—it is not drawn at all. It is an entirely different personage in different chapters; and it has here and there a very unpleasant touch which must have come of rapid writing. Yet so admirable are many parts of the book that it cannot be left out of the list of Thackeray's most considerable works. *Denis Duval*, which reached only three numbers, promised to be a first-rate work, more or less in the *Esmond* manner. The author died while it was in progress, on the day before Christmas day, 1863. He was buried in Kensal Green, and a bust by Marochetti was put up to his memory in Westminster Abbey.

Little has yet been said of Thackeray's performances in poetry. They formed a small but not the least significant part of his life's work. The grace and the apparent spontaneity of his versification are beyond question. Some of the more serious efforts, such as *The Chronicle of the Drum* (1841), are full of power, and instinct with true poetic feeling. Both the half-humorous half-pathetic ballads and the wholly extravagant ones must be classed with the best work in that kind; and the translations from Béranger are as good as verse translations can be. He had the true poetic instinct, and proved it by writing poetry which equalled his prose in grace and feeling.

It is not necessary to discuss the precise place which Thackeray will in future hold, in respect to his immediate contemporaries. What seems absolutely certain is that the force and variety of his genius and art will always hold for him a place as one of the greatest of English novelists and essayists, and, it should be added, as by no means the least of English critics.

(W. H. P.)

THALBERG, Sigismond (1812–1871), a celebrated pianist and composer for his instrument, was born at Geneva in 1812 (May 5 or January 7). In 1822 he was taken to Vienna, where, under the watchful care of Count Dietrichstein, his education was completed. There is some doubt as to the masters under whom he studied; but it is certain that he received instruction from Hummel, and perhaps also from Czerny, and that he took lessons in composition from Sechter. He made his first appearance as a pianist at Prince Metternich's in 1826, and published his first composition—a *Fantasia on Airs from "Euryanthe"*—in 1828, but it was not until 1830 that he was first fairly introduced to the public, with such brilliant success that from that time forward his only rival was Liszt. In 1834 he was appointed "kammervirtuos" to the emperor of Austria. He first appeared in Paris in 1837; and in 1838 he came to England, astonishing his hearers with the novel effects produced in his *Variations on God Save the Queen*, while he charmed them with his delicate touch and the purity of his expression. Thenceforward his career was a succession of triumphs. In order to disprove the popular idea that he could execute no music but his own, he played Beethoven's *Concerto in C minor* (op. 37) at the London Wednesday Concerts, held in 1846–47 at Exeter Hall, with a keen intelligence which proved his power of interpreting the works of the great masters to be at least on a level with his wonderful *technique.* Besides his pianoforte compositions, which are almost innumerable, Thalberg produced two operas,—*Cristina*, which proved a complete failure, and *Florinda*, which fared but little better at Her Majesty's Theatre in 1851. He played in London for the last time in 1863, and afterwards retired to his estate near Naples. He died at Naples, April 27, 1871.

THALES of Miletus (640–546 B.C.), son of Examyus and Cleobuline, is universally recognized as the founder of Greek geometry, astronomy, and philosophy. He is said by Herodotus and others to have been of Phœnician extraction, but the more common account (see Diogenes Laertius) is that he was a native Milesian of noble birth. Zeller thinks that his ancestors belonged to the Cadmean tribe in Bœotia, who were intermingled with the Ionians of Asia Minor, and thus reconciles the conflicting statements. The nationality of Thales is certainly Greek and not Phœnician. The high estimation in which he was held by his contemporaries is shown by the place he occupied as chief of the seven "wise men" of Greece; and in later times amongst the ancients his fame was quite remarkable. It is well known that this name (σοφός) was given on account of practical ability; and in accordance with this we find that Thales had been occupied with civil affairs, and indeed several instances of his political sagacity have been handed down. Of these the most remarkable is the advice, praised by Herodotus, which he gave to his fellow-countrymen "before Ionia was ruined,"—"that the Ionians should constitute one general council in Teos, as the most central of the twelve cities, and that the remaining cities should nevertheless be governed as independent states" (Herod., i. 170). It is probable, however, that in the case of Thales the appellation "wise man," which was given to him and to the other six in the archonship of Damasius (586 B.C.),[1] was conferred on him not only on account of his political sagacity, but also for his scientific eminence (Plut., *Solon*, c. 3). To about the same time must be referred his celebrated prediction of the eclipse of the sun, which took place on May 28, 585 B.C. This event, which was of the highest importance, has given rise to much discussion. The account of it as given by Herodotus (i. 74) contains two statements: (1) the fact that the eclipse did actually take place during a battle between the Medes and the Lydians, that it was a total eclipse (Herodotus calls it a "night battle"), that it caused a cessation of hostilities and led to a lasting peace between the contending nations; (2) that Thales had foretold the eclipse to the Ionians, and fixed the year in which it actually did take place. Various dates—ranging from 625 B.C. to 583 B.C.—have been assigned by different chronologists to this eclipse; but, since the investigations of Airy,[1] Hind,[2] and Zech,[3] the date determined by them (May 28, 585 B.C.) has been generally accepted. This date agrees nearly with that given by Pliny (*H. N.*, ii. 12). The second part of the statement of Herodotus—the reality of the prediction by Thales—has been frequently called in question, chiefly on the ground that, in order to predict a solar eclipse with any chance of success, one should have the command of certain astronomical facts which were not known until the 3d century B.C., and then merely approximately, and only employed with that object in the following century by Hipparchus. The question, however, is not whether Thales could predict the eclipse of the sun with any chance of success—much less whether he could state beforehand at what places the eclipse would be visible, as some have erroneously supposed, and which of course would have been quite impossible for him to do, but simply whether he foretold that there would be a solar eclipse in that year, as stated by Herodotus. Now as to this there is quite a remarkable unanimity in the testimony of the ancients, and the evidence is of the strongest kind, ascending to Herodotus, and, according to the account of Diogenes Laertius, even to Xenophanes, who was an Ionian, and not much later than Thales. Further, we know that in the 8th century B.C. there were observatories in most of the large cities in the valley of the Euphrates, and that professional astronomers regularly took observations of the heavens, copies of which were sent to the king of Assyria; and from a cuneiform inscription found in the palace of Sennacherib at Nineveh, the text of which is given by George Smith,[4] we learn that at that time the epochs of eclipses of both sun and moon were predicted as possible—probably by means of the cycle of 223 lunations or Chaldæan Saros—and that observations were made accordingly.

---

[1] Bretschneider (*Die Geom. vor Euklides*, p. 40), without stating his authority, gives "between 585 and 583 B.C." as the date of the archonship of Damasius. In this he is followed by some other recent writers, who infer thence that the name "wise" was conferred on Thales on account of the success of his prediction. The date 586 B.C., given above, which is taken from Clinton, is adopted by Zeller.

The wonderful fame of Thales amongst the ancients must have been in great part due to this achievement, which seems, moreover, to have been one of the chief causes that excited amongst the Hellenes the love of science which ever afterwards characterized them. Thales seems not to have left any writings behind him, though as to this there appears to be some doubt (see Diog. Laer., i. 23). Many anecdotes, amusing rather than instructive, are related of him, which have been handed down by Diogenes Laertius and other writers. From some of them it would appear that he was engaged in trade, which is indeed expressly stated by Plutarch (*Solon*, c. 2). It is probable that in the pursuit of commerce he was led to visit Egypt. Of the fact that Thales visited Egypt, and there became acquainted with geometry, there is abundant evidence. Hieronymus of Rhodes (ap. Diog. Laer., i. 27) says, "he never had any teacher except during the time when he went to Egypt and associated with the priests."[5]

But the characteristic feature of the work of Thales was that to the knowledge thus acquired he added the capital creation of the geometry of lines, which was essentially abstract in its character. The only geometry known to the Egyptian priests was that of surfaces, together with a sketch of that of solids, a geometry consisting of some simple quadratures and elementary cubatures, which they had obtained empirically. Thales, on the other hand, introduced *abstract* geometry, the object of which is to establish precise relations between the different parts of a figure, so that some of them could be found by means of others in a manner strictly rigorous. This was a phenomenon quite new in the world, and due, in fact, to the abstract spirit of the Greeks.

The following discoveries in geometry are attributed to Thales: (1) the circle is bisected by its diameter (Procl., *op. cit.*, p. 157); (2) the angles at the base of an isosceles triangle are equal (Id., p. 250); (3) when two straight lines cut each other the vertically opposite angles are equal (Id., p. 299); (4) the angle in a semicircle is a right angle;[6] (5) the theorem Euclid i. 26 is referred to Thales by Eudemus (Procl., *op. cit.*, p. 352). Two applications of geometry to the solution of practical problems are also attributed to him: (1) the determination of the distance of a ship at sea, for which he made use of the last theorem; (2) the determination of the height of a pyramid by means of the length of its shadow; according to Hieronymus of Rhodes (Diog. Laert., i. 27) and Pliny (*N. H.*, xxxvi. 17), the shadow was measured at the hour of the day when a man's shadow is the same length as himself. Plutarch, however, states the method in a form requiring the knowledge of Euclid vi. 4, but without the restriction as to the hour of the day (*Sept. Sap. Conviv.*, 2). Further, we learn from Diogenes Laertius (i. 25) that he perfected the things relating to the scalene triangle and the theory of lines. Proclus, too, in his summary of the history of geometry before Euclid, which he probably derived from Eudemus of Rhodes, says that Thales, having visited Egypt, first brought the knowledge of geometry into Greece, that he discovered many things himself, and communicated the beginnings of many to his successors, some of which he attempted in a more abstract manner (*καθολικώτερον*) and some in a more intuitional or sensible manner (*αισθητικώτερον*) (*op. cit.*, p. 65).

From these indications it is no doubt difficult to determine what Thales brought from Egypt and what was due to his own invention. This difficulty has, however, been lessened since the translation and publication of the papyrus Rhind by Eisenlohr;[7] and it is now generally admitted that, in the distinction made in the last passage quoted above from Proclus, reference is made to the two forms of his work,—*αισθητικώτερον* pointing to what he derived from Egypt or arrived at in an Egyptian manner, while *καθολικώτερον* indicates the discoveries which he made in accordance with the Greek spirit. To the former belong the theorems (1), (2), and (3), and to the latter especially the theorem (4), and also, probably, his solution of the two practical problems. We infer, then, [1] that Thales must have known the theorem that the sum of the three angles of a triangle are equal to two right angles. This inference is made from (4) taken along with (2). No doubt we are informed by Proclus, on the authority of Eudemus, that the theorem Euclid i. 32 was first proved in a general way by the Pythagoreans (see PYTHAGORAS, vol. xx. p. 146); but, on the other hand, we learn from Geminus that the ancient geometers observed the equality to two right angles in each kind of triangle—in the equilateral first, then in the isosceles, and lastly in the scalene (Apoll., *Conica*, ed. Halleius, p. 9), and it is plain that the geometers older than the Pythagoreans can be no other than Thales and his school. The theorem, then, seems to have been arrived at by induction, and may have been suggested by the contemplation of floors or walls covered with tiles of the form of equilateral triangles, or squares, or hexagons. [2] We see also in the theorem (4) the first trace of the important conception of geometrical loci, which we, therefore, attribute to Thales. It is worth noticing that it was in this manner that this remarkable property of the circle with which, in fact, abstract geometry was inaugurated, presented itself to the imagination of Dante:

> "O se del mezzo cerchio far si puote
> Triangol si, ch'un retto non avesse."—*Par.*, c. xiii. 101.

[3] Thales discovered the theorem that the sides of equiangular triangles are proportional. The knowledge of this theorem is distinctly attributed to Thales by Plutarch, and it was probably made use of also in his determination of the distance of a ship at sea.

Let us now consider the importance of the work of Thales. I. In a scientific point of view: (*a*) we see, in the first place, that by his two theorems he founded the geometry of lines, which has ever since remained the principal part of geometry; (*b*) he may, in the second place, be fairly considered to have laid the foundation of algebra, for his first theorem establishes an equation in the true sense of the word, while the second institutes a proportion.[1] II. In a philosophic point of view: we see that in these two theorems of Thales the first type of a natural law, *i.e.*, the expression of a fixed dependence between different quantities, or, in another form, the disentanglement of constancy in the midst of variety—has decisively arisen.[2] III. Lastly, in a practical point of view: Thales furnished the first example of an application of theoretical geometry to practice,[3] and laid the foundation of an important branch of the same—the measurement of heights and distances. For the further progress of geometry see PYTHAGORAS.

N.*, xxxvi. 12; Iamblichus, *In Vit. Pythag.*, 12; Plutarch, *Sept. Sap. Conviv.*, 2, *De Iside*, 10, and *Plac.*, i. 3, 1.

[6] This is unquestionably the meaning of the statement of Pamphila (temp. Nero), ap. Diog. Laert., i. 24, that he was the first person to describe a right-angled triangle in a circle.

[7] *Ein mathematisches Handbuch der alten Aegypter*, Leipsic, 1877.

As to the astronomical knowledge of Thales we have the following notices: (1) besides the prediction of the solar eclipse, Eudemus attributes to him the discovery that the circuit of the sun between the solstices is not always uniform;[4] (2) he called the last day of the month the thirtieth (Diog. Laert., i. 24); (3) he divided the year into 365 days (Id., i. 27); (4) he determined the diameter of the sun to be the 720th part of the zodiac;[5] (5) he appears to have pointed out the constellation of the Lesser Bear to his countrymen, and instructed them to steer by it [as nearer the pole] instead of the Great Bear (Callimachus ap. Diog. Laert., i. 23; *cf.* Aratus, *Phænomena*, v. 36 *sq.*). Other discoveries in astronomy are attributed to Thales, but on authorities which are not trustworthy. He did not know, for example, that "the earth is spherical," as is erroneously stated by Plutarch (*Placita*, iii. 10); on the contrary, he conceived it to be a flat disk, and in this supposition he was followed by most of his successors in the Ionian schools, including Anaxagoras. The doctrine of the sphericity of the earth, for which the researches of Anaximander had prepared the way,[6] was in fact one of the the great discoveries of Pythagoras, was taught by Parmenides, who was connected with the Pythagoreans, and remained for a long time the exclusive property of the Italian schools.[7]

Whilst in virtue of his political sagacity and intellectual eminence Thales held a place in the traditional list of the wise men, on the strength of the disinterested love of knowledge which appeared in his physical speculations he was accounted a "philosopher" (φιλόσοφος). His "philosophy" is usually summed up in the dogma "water is the principle, or the element, of things;" but, as the technical terms "principle" (ἀρχή) and "element" (στοιχεῖον) had not yet come into use, it may be conjectured that the phrase "all things are water" (πάντα ὕδωρ ἐστί) more exactly represents his teaching. Writings which bore his name were extant in antiquity; but, as Aristotle, when he speaks of Thales's doctrine, always depends upon tradition, there can be little doubt that they were forgeries.

From Aristotle we learn (1) that Thales found in water the origin of things; (2) that he conceived the earth to float upon a sea of the elemental fluid; (3) that he supposed all things to be full of gods; (4) that in virtue of the attraction exercised by the magnet he attributed to it a soul. Here our information ends. Aristotle's suggestion that Thales was led to his fundamental dogma by observation of the part which moisture plays in the production and the maintenance of life, and Simplicius's, that the impressibility and the binding power of water were perhaps also in his thoughts, are by admission purely conjectural. Simplicius's further suggestion that Thales conceived the element to be modified by thinning and thickening is plainly inconsistent with the statement of Theophrastus that the hypothesis in question was peculiar to Anaximenes. The assertion preserved by Stobæus that Thales recognized, together with the material element "water," "mind," which penetrates it and sets it in motion, is refuted by the precise testimony of Aristotle, who declares that the early physicists did not distinguish the moving cause from the material cause, and that before Hermotimus and Anaxagoras no one postulated a creative intelligence.

It would seem, then, that Thales sought amid the variety of things a single material cause; that he found such a cause in one of the forms of matter most familiar to him, namely, water, and accordingly regarded earth and all that it contains as water variously metamorphosed; and that, asking himself no questions about the manner of its transformation, he was content "to see in the forces of nature present deities" (Zeller).

The doctrine of Thales was interpreted and developed in the course of three succeeding generations. First, Anaximander chose for what he called his "principle" (ἀρχή), not water, but a corporeal element intermediate between fire and air on the one hand and water and earth on the other. Next, Anaximenes, preferring air, resolved its transformations into processes of thinning and thickening. Lastly, Heraclitus asserted the claims of fire, which he conceived to modify itself, not occasionally, but perpetually. Thus Thales recognized change, but was not careful to explain it; Anaximander attributed to change two directions; Anaximenes conceived the two sorts of change as rarefaction and condensation; Heraclitus, perceiving that, if, as his predecessors had tacitly assumed, change was occasional, the interference of a moving cause was necessary, made change perpetual. But all four agreed in tracing the variety of things to a single material cause, corporeal, endowed with qualities, and capable of self-transformation. A new departure was taken by the Eleatic Parmenides (see vol. xviii. p. 320), who, expressly noting that, when Thales and his successors attributed to the supposed element changing qualities, they were untrue to the principle of monism, required that the superficial plurality of nature should be strictly distinguished from its fundamental unity. Hence, whereas Thales and his successors had confounded the One, the element, and the Many, its modifications, the One and the Not-One or Many became with Parmenides matters for separate investigation. In this way two lines of inquiry originated. On the one hand Empedocles and Anaxagoras, abandoning the pursuit of the One, gave themselves to the scientific study of the Many; on the other Zeno, abandoning the pursuit of the Many, gave himself to the dialectical study of the One. Both successions were doomed to failure; and the result was a skepticism from which the thought of Greece did not emerge until Plato, returning to Parmenides, declared the study of the One and the Many, jointly regarded, to be the true office of philosophy. Thus, meagre and futile as the doctrine of Thales was, all the Greek schools, with the solitary exception of that of Pythagoras, took their origin from it. Not in name only, but also in fact, Thales, the first of the Ionian physicists, was the founder of the philosophy of Greece.

THALLIUM, one of the rarer elements of chemistry. Its discovery is one of the outcomes of Bunsen and Kirchhof's method of spectrum analysis. When Crookes, in 1861, applied this method to the flue-dust produced in the roasting of a certain kind of pyrites he observed in its spectrum a green line foreign to all then known spectra, and concluded that his substance must contain a new element, to which he gave the name of *thallium*, from θαλλός, a green twig. Crookes presumed that his thallium was something of the order of sulphur, selenium, or tellurium; but Lamy, who anticipated him in isolating the new element, found it to be a metal. Our present knowledge of the chemistry of thallium is based chiefly upon the labors of Crookes.

The chemical character of thallium presents striking peculiarities. Dumas once called it the "*ornithorhynchus paradoxus* of metals." As an elementary substance, it is very similar in its mechanical and physical properties to lead; like lead it forms an almost insoluble chloride and an insoluble iodide. But the hydroxide of thallium, in most of its properties, comes very close to those of the alkali metals; it is strongly basilous, forms an insoluble chloroplatinate, and an alum strikingly similar to the corresponding potassium compounds. Yet, unlike potassium or lead, it forms a feebly basic sesquioxide similar to manganic oxide, Mn_2O_3.

Traces of thallium exist in many kinds of pyrites, as used for vitriol-making. The only known mineral of which it forms an essential component is the "crookesite" of Skrikerum, Småland, Sweden, which, according to Nordenskiöld, contains 33.3 of selenium, 45.8 of copper, 3.7 of silver, and 17.2 of thallium in 100 parts. Crookesite, however, is scarce. The best raw materials for the preparation of thallium are the flue-dusts produced industrially in the roasting of thalliferous pyrites and the "chamber muds" accumulating in vitriol-chambers wrought with such pyrites; in both it is frequently associated with SELENIUM (*q.v.*). The flue-dust from the pyrites of Theux, near Spa (Belgium), according to Böttcher, contains 0.5 to 0.75 per cent. of thallium; that of the pyrites of Meggen, according to Carstanjen, as much as 3.5 per cent.; while that of the pyrites of Ruhrort yielded 1 per cent. of the pure chloride to Gunning.

For the extraction of the metal from chamber mud, the latter is boiled with water, which extracts the thallium as Tl_2SO_4. From the filtered solution the thallium is precipitated by addition of hydrochloric acid, as TlCl, along, in general, with more or less of chloride of lead. The mixed chlorides are boiled down to dryness with oil of vitriol to convert them into sulphates, which are then separated by boiling water, which dissolves only the thallium salt. From the filtered solution the thallium is recovered, as such, by means of pure metallic zinc, or by electrolysis. The (approximately pure) metallic sponge obtained is washed, made compact by compression, fused in a porcelain crucible in an atmosphere of hydrogen, and cast into sticks. Methods for the final purification of the metal will easily be deduced from what follows.

The *metal* is bluish white; it is extremely soft but almost devoid of tenacity and elasticity. Its specific gravity is 11.86. It fuses at 290° C.; at a white heat it boils and can be distilled in hydrogen gas. When heated in air it is readily oxidized, with formation of a reddish or violet vapor. When exposed to the air it readily draws a film of oxide; the tarnished metal when plunged into water reassumes its metallic lustre, the oxide film being quickly dissolved. When kept in contact with water and air it is gradually converted into hydroxide, Tl_2OH_2O or TlOH.

This *hydrate*, TlOH, most conveniently prepared by decomposing the solution of the sulphate with baryta water, crystallizes from its solution in long, yellow needles, TlOH or $TlOH + H_2O$, which dissolve readily in water, forming an intensely alkaline solution, which acts as a caustic, like, for instance, potash-lye, and like it greedily absorbs carbonic acid from the atmosphere. But, unlike the alkalies, it readily loses its water at 100° C. and even at the ordinary temperature, to pass into the state of anhydrous Tl_2O, which is black or black-violet.

The *chloride*, TlCl, is readily obtained from the solution of any thallous salt (*e.g.*, the sulphate), by addition of hydrochloric acid, as a white precipitate similar in appearance to chloride of silver, like which it turns violet in the light and fuses below redness into a (yellow) liquid which freezes into a horn-like flexible mass. The specific gravity of this "horn" thallium, as one might call it, is 7.02. One part of the precipitated chloride dissolves at 0° C. in 500 parts of water, and in 70 parts at 100° C. It is less soluble in dilute hydrochloric acid. Carbonate of soda solution dissolves it pretty freely.

The *iodide*, TlI, is a yellow precipitate, which requires 16,000 parts of cold water and still more of solution of iodide of potassium for its solution.

The *chloroplatinate*, $PtCl_6Tl_2$, readily obtainable from thallous-salt solutions by addition of chloride of platinum ($PtCl_6H_2$), is a yellow precipitate soluble in no less than 15,600 parts of cold water.

The *carbonate*, Tl_2CO_3, comes closer to the lithium compound than to any other ordinary carbonate. It forms resplendent monoclinic prisms, soluble at 18° C. in 19.1 and at 100° in 4.46 parts of water. A stable bicarbonate, $TlHCO_3$, does exist.

The *sulphate*, Tl_2SO_4, forms rhombic prisms isomorphous with K_2SO_4. It dissolves at 18° C. in 20.8 and at 101° in 5.2 parts of water. It unites with vitriol into an acid salt, $TlHSO_4 + 3H_2O$, and with sulphate of alumina into an "alum," $Al_2(SO_4)_3Tl_2So_4 + 24H_2O$.

Thallic salts are related to thallous pretty much as manganic are to manganous. The chloride, $TlCl_3$, is obtained as a solution by passing chlorine into a suspension of thallous chloride in water. The solution, when evaporated *in vacuo*, deposits colorless crystals, $TlCl_3 + H_2O$. For the oxide, if chlorine be passed into a solution of thallous chloride in carbonate of soda a brown precipitate is produced, which, after drying, has the composition $Tl_2O_3 + H_2O$. When heated with strong hydrochloric acid it evolves chlorine and yields TlCl; when heated with oil of vitriol it yields oxygen gas and thallous sulphate. Thallic sulphate, however, does exist,—in crystals, $Tl_2(SO_4)_3 + 7H_2O$, soluble in dilute sulphuric acid, but decomposed by water, with precipitation of hydrated Tl_2O_3.

Analysis.—All thallium compounds volatile or liable to dissociation at the temperature of the flame of a Bunsen lamp impart to such flame an intense green color. The spectrum consists of only one line, which, of course, has a definite position in the spectrum, and consequently is easily identified,—a most delicate test.

From solutions containing it as thallous salt the metal is easily precipitated as chloride, iodide, or chloroplatinate by the corresponding reagents (see *supra*). Sulphuretted hydrogen, in the presence of free mineral acid, gives no precipitate; sulphide of ammonium, from neutral solutions, precipitates Tl_2S as a dark brown or black precipitate, insoluble in excess of reagent. Thallic salts are easily reduced to thallous by means of solution of sulphurous acid, and thus rendered amenable to the above reactions.

The atomic weight of thallium was determined very carefully by Crookes. He found it $Tl = 204.2$,—O being 16.

(W. D.)

THAMES, the most important river in Great Britain, has its source in several streams on the Gloucestershire border, the main one having its rise in the parish of Coates, 3 miles southwest of Cirencester. The upper part of the river, until the junction with the Thame near Dorchester, is generally called the Isis, a usage to which Camden perhaps gave currency, who derives the word Tamesis or Thames from the junction of the names of the two rivers, the Thame and Isis. The total length of the river from Thames Head to London Bridge is 170 miles, and to Sheerness 228 miles. It drains an area of 6100 miles. It becomes navigable 24 miles from its source, near Lechlade, its waters having been greatly augmented by the junction of the Colne, Leach, and Churn; here also is the junction with the Thames and Severn Canal. The height of its source above sea-level is 370 feet, and that of the stream at Lechlade 250 feet, the average fall between Lechlade and London Bridge (146 miles) being 21 inches per mile. The course is remarkably equable throughout. Above Teddington, 19 miles from London Bridge, the tidal wave may be said to cease, and thence up to Lechlade navigation is carried on by the aid of locks. A small steamer plies as high as Oxford. While at Lechlade the daily flow of the ordinary summer level is about 100 million gallons, the flow at Teddington is about 380 million gallons. There are seven hours of ebb tide and five hours of flow tide. From the Nore to London Bridge, a distance of 40 miles, the tidal wave travels in two hours, and in other two hours it reaches Teddington. The width of the river at Teddington is 250 feet, and at London Bridge the width at high tide is 800 feet, the depth being 30 feet, while at low tide the width is 650 feet and the depth 12 feet. Large barges can ascend the river 150 miles above London Bridge, vessels of 200 tons as high as the bridge, and of 400 tons to the Pool, below which, at Irongate and St. Katherine's wharf, deep-sea steamer navigation commences, while vessels of any tonnage can come as high as Deptford.

The Thames leaves the Gloucestershire and Wiltshire border near Buscot, after which it separates successively Berks and Oxford, Berks and Bucks, Middlesex and Surrey, and, finally, at its estuary, Essex and Kent. Below Lechlade it has a winding course, passing near Farringdon and Bampton. After receiving the Windrush, it passes near the grounds of Blenheim, whence it receives from the left the Evenlode, and at Oxford it receives from the left the Cherwell. It then flows in a southerly direction to Abingdon, where it receives on the right the Ock from the valley of the White Horse, and has a junction with the Wilts and Berks Canal. Turning in an easterly direction it is joined, about a mile after passing Dorchester, by its principal affluent the Thame. Thence, through an opening of the Chiltern Hills, it passes Bensington, and turns southwards by Wallingford and Reading, where it receives the Kennet from the right. It then bends northward to Henley, eastward to Great Marlow, and southward to Maidenhead, where it receives from the right the Loddon. Winding in a southeasterly direction it passes Eton, Windsor, Datchet, Staines, and Chertsey, receiving at Staines the Colne from the left. Flowing through the grounds of Hampton Court it reaches Kingston and Teddington, where its bulk is increased by the tidal wave. From Richmond, where it receives the Mole, it begins to pass the villas and suburbs of London. At Gravesend, 27 miles below London, it has a width of half a mile, and at the Nore lighthouse, 50 miles below London Bridge, the estuary widens to nearly 10 miles. In the tidal reaches the principal affluents of the Thames are the Mole at Richmond, the Brent at Brentford, the Wandle at Wandsworth, the Lea at Blackwall, the Roding at Barking Creek, the Ingrebourne at Rainham, and the Medway at Sheerness. The land adjoining the river is greatly subject to floods, and from above London there were in ancient times wide stretches of marsh land covered by shallow lagoons. The embankments below London Bridge date possibly from the time of the Romans, but their origin is the subject of much dispute (see LONDON, vol. xiv. p. 850). Between London Bridge and Chelsea the bed of the river has been altered artificially, and flooding is prevented by a marine wall (see LONDON, vol. xiv. p. 832). The Thames occupies the bed of a much larger prehistoric river, the gravels of which adjoin its banks at a considerable distance.

The scenery, though scarcely to be called picturesque, and in a certain sense monotonous, has a peculiar charm from the richness of its sylvan beauty and its pleasant alternation of hill and dale. The number of islands that occur in the course of the river add to its interest, and afford convenient seclusion for the erection of boat-houses and tents. The Thames vies with the Tyne as the principal river for boat-racing in England, and of course greatly surpasses the latter river as regards amateur boat-racing, the principal fixtures in which are the Oxford and Cambridge boat-race and the Henley regatta. The river affords about one-half of the water supply of London, and is the principal outlet for its sewage. It is under the government of conservators, originally constituted in 1857, but their duties have been extended by several subsequent Acts.

See *The River Thames from Oxford to the Sea*, 1859; Cassell's *Royal River* (richly illustrated), 1885; Huxley's *Physiography*, 1877; and Dickens's *Dictionary of the Thames*.

THÁNA, or TANNAH, a district in Bombay presidency, India, with an area of 4243 square miles, lying between 18° 42′ and 20° 20′ N. lat. and 72° 45′ and 73° 48′ E. long. It extends along the coast for 105 miles, with a breadth of 50 miles, and is confined between the Sahyádri Gháts on the E. and the sea on the W., while on the N. it is bounded by the Portuguese territory of Daman and by Surat district, and on the S. by Kolába and Poona districts. The district is well watered and wooded, and, except in the northeast, is a low-lying rice tract broken by hills. The spurs of the Gháts form health resorts; the two most conspicuous hills are Mátherán and Tungár. Most of the hills were once fortified, but the forts built on them are now dilapidated and useless. The only rivers of any importance are the Vaitarna and the Ulhás, the former being navigable to a distance of about 20 miles from its mouth; the latter is also navigable in parts for small craft. There are no lakes; but the Vehár and the Tulsi, formed artificially, supply Bombay city with water. The forests, lying chiefly in the northern half of the district, occupy 1664 square miles, or about 40 per cent. of the total area. The average annual rainfall exceeds 90 inches.

In 1881 the population of Thána was returned at 908,548 (males 468,236, females 440,312); Hindus numbered 806,805, Mohammedans 42,391, and Christians 39,545. The district has seven towns with populations exceeding 10,000, namely, Bandra (14,987), THÁNA (see below), Bhiwandi (13,837), Kalyan (12,910), Bassein (10,357). Panvel (10,351), Uran (10,149). The area under cultivation in 1885–86 was 1,002,448 acres, and 768,057 remained uncultivated. The total area of crops was 522,810 acres, including 5835 twice cropped. Rice is by far the most important product, and occupied 321,680 acres; it is also the chief article of export. Sugar-cane and plantains are cultivated largely, as well as mangoes and cocoa-nuts. In 1885–86 the gross revenue of the district was £245,182 [$1,191,584.52], the land yielding £130,409 [$633,787.74]. The territory comprised in the district of Thána formed part of the dominions of the peshwá, and was annexed by the British in 1818 on the overthrow of Baji ráo. Since then the operations to put down the Koli robbers, which extended over several years, have been the only cause of serious trouble, and lately, in 1874 and 1877, there were a number of gang robberies which were suppressed, but not without difficulty.

THÁNA, chief town of the above district and a station on the Great Indian Peninsula Railway, lies 20 miles northeast of Bombay city, in 19° 11′ 30″ N. lat. and 73° 1′ 30″ E. long., and in 1881 had a population of 14,456 (males 7856, females 6600). It is a municipal town and a port, and contains a civil hospital and post-office.

THANE, or THEGN. See ENGLAND, vol. viii. p. 248; and NOBILITY, vol. xvii. p. 542.

THAPSACUS. See MESOPOTAMIA, vol. xvi. p. 53.

THAR AND PÁRKAR, or THUR AND PARKER, a district in the east of Sind, Bombay presidency, India, with an area of 12,729 square miles. It lies between 24° 13′ and 26° 15′ N. lat. and between 68° 51′ and 71° 8′ E. long., and is bounded on the N. by Khaipur state, on the E. by the states of Jaisalmir, Malani, and Jodhpur, on the W. by Hyderabad district, and on the S. by the Runn of Cutch. The district is divided into two portions. The western part, called the "Pat," is watered by the Eastern Nara and the Mithrau canals, which constitute the sole water-system of the district, and the presence of water has created a quantity of jungle and marsh; the other part, called the "Thar," is a desert tract of rolling sand-hills, running northeast and southwest, composed of a fine but slightly coherent sand. To the southeast of Thar is Párkar, where there are ranges of rocky hills, rising to 350 feet above the surrounding level, and open plains of stiff clay. The Párkar portion of the district contains the ruins of several old temples; one of these is a Jain temple, which contained an idol of great sanctity and repute, known under the name of Gorcha. The climate is subject to considerable extremes in temperature, being excessively hot in the summer and very cold in winter, the cold increasing as the sand-hills are approached.

The census of 1881 returned the population at 203,344 (males 112,400, females 90,944); Hindus numbered 43,755, Mohammedans 109,924, and Christians only 14. Umarkot, the birthplace of Akbar, is the chief town, with a population of 2828. The chief products of the district are rice, joár, bajri, cotton, and oil-seeds. It is estimated that only 45 per cent. of the arable area is under cultivation. The exports are chiefly rice, wheat, oil-seeds, cattle, goats, and sheep; the imports consist of cotton, metals, dried fruits, piece goods, sugar, and tobacco. The manufactures are chiefly blankets, camel saddles, and coarse cotton cloth. The imperial revenue in 1885–86 amounted to £44,313 [$215,361.18], of which the land supplied £32,927 [$159,539.22].

Very little is known of the early history of the district. The Soda Rajputs, said to be descendants of Parmar Soda, are supposed to have come into this part of Sind about 1226, when they quickly displaced the rulers of the country, though, according to other authorities, they did not conquer the country from the Sumras, the dominant race, before the beginning of the 16th century. The local dynasty of the Sodas succumbed to the Kalhoras about 1750, since which period the district has been subject more or less to Sind. The Talpur mirs succeeded the Kalhoras, and built a number of forts to overawe the people, who were lawless and addicted to robbery. On the British conquest of Sind in 1843 the greater part of the district was made over to Cutch; and in 1856 it was wholly incorporated in the province of Sind. In 1859 a rebellion broke out, which was quickly suppressed.

THARRAWADDY, a district in the Pegu division of Burmah, with an area of 2014 square miles. It lies between 17° 30′ and 18° 40′ N. lat. and between 95° 20′ and 96° 10′ E. long., and is bounded on the N. by

Prome, on the E. by the Pegu Yoma range, on the S. by Hanthawaddy, and on the W. by Henzada. The Pegu Yoma range separates Tharrawaddy from Toungú district, and forms the water-parting between the rivers Irrawaddy and Sittang; there are also many small elevations. The Irrawaddy, which traverses the district for 46 miles, is the principal navigable river. Another important river is the Hlaing, which runs through the district from north to south, receiving from the east, through numerous channels, the drainage of the Pegu Yoma Mountains, which fertilizes the plain on its eastern bank. There are twenty-three teak forests and four fuel reserves in the district, covering an area of 817 square miles. Among the wild animals generally found in the mountains are the elephant, rhinoceros, bison, and various kinds of feathered game.

In 1881 the population was returned at 278,155 (males 143,413, females 134,742), of whom 1985 were Hindus, 1110 were Mohammedans, 270,552 were Buddhists, whilst Christians and aborigines numbered 2363 and 2135 respectively. The area under cultivation in 1885–86 comprised 323,542 acres, and that available for cultivation 186,002 acres; forests occupied 364,524 acres. The chief products of the district are rice, sesamum, tobacco, sugar-cane, cotton, and fruits. The gross revenue of Tharrawaddy in 1885–86 was £85,254 [$414,334.44], of which the land yielded £51,523 [$250,401.78]. The history of the district is identical with that of HENZADA (*q.v.*). Tharrawaddy was formed in 1878 out of that portion of Henzada lying east of the Irrawaddy. Its headquarters are at Thoon-tshay, on the stream of the same name.

THASOS, an island in the north of the Ægean Sea, off the coast of Thrace, 3¼ miles distant from the plain of the river Nestus (now the Kara-Su). The island was colonized at an early date by Phœnicians, attracted probably by its gold mines; they founded a temple of Hercules, which still existed in the time of Herodotus. Thasus, son of Phœnix, is said to have been the leader of the Phœnicians, and to have given his name to the island. In 720 or 708 B.C. Thasos received a Greek colony from Paros. In a war which the Parian colonists waged with the Saians, a Thracian tribe, the poet Archilochus threw away his shield. The Greeks extended their power to the mainland, where they owned gold mines which were even more valuable than those on the island. From these sources the Thasians drew great wealth, their annual revenues amounting to 200 or even 300 talents. Herodotus, who visited Thasos, says that the best mines on the island were those which had been opened by the Phœnicians on the east side of the island, facing Samothrace. After the capture of Miletus (494 B.C.) Histiæus laid siege to Thasos. The attack failed, but, warned by the danger, the Thasians employed their revenues to build war ships and strengthen their fortifications. This excited the suspicions of the Persians, and Darius compelled them to surrender their ships and pull down their walls. After the defeat of Xerxes the Thasians joined the Greek confederacy; but afterwards (in 467, 465, or 464, according to different calculations), on account of a difference about the mines and marts on the mainland, they revolted. The Athenians defeated them by sea, and, after a siege that lasted more than two years, took the capital, Thasos, and compelled the Thasians to destroy their walls, surrender their ships, pay an indemnity and an annual contribution, and resign their possessions on the mainland. In 411 B.C., at the time of the oligarchical revolution at Athens, Thasos again revolted from Athens and received a Lacedæmonian governor; but in 407 the partisans of Lacedæmon were expelled, and the Athenians under Thrasybulus were admitted. After the battle of Ægospotami (405 B.C.), Thasos again fell into the hands of the Lacedæmonians; but the Athenians must have recovered it, for it formed one of the subjects of dispute between them and Philip of Macedonia. In the embroilment between Philip III. of Macedonia and the Romans, Thasos submitted to Philip, but received its freedom at the hands of the Romans after the battle of Cynoscephalæ (197 B.C.), and it was still a "free" state in the time of Pliny. Thasos, the capital, stood on the north side of the island, and had two harbors, one of which was closed. Archilochus described Thasos as "an ass's backbone crowned with wild wood," and the description still suits the mountainous island with its forests of fir. The highest mountain, Ipsario, is 3428 feet high. Besides its gold mines, the wine, nuts, and marble of Thasos were well known in antiquity. The mines and marble quarries are no longer worked; and the chief exports are now fir timber for shipbuilding, olive oil, honey, and wax. The imports consist of manufactured goods, beasts of burden, and corn, for the island is too mountainous to grow enough corn for the inhabitants.

In 1858 the population, distributed in ten villages, was estimated at 10,000. The people are Greek Christians and do not differ in appearance from the inhabitants of the other Greek islands. The villages are mostly situated at some distance from the sea; for the island suffered from pirates up to a time within living memory. In the early part of this century sentinels stood on duty night and day, and at a signal of alarm the whole population, including the Turkish aga himself, used to hide in the woods. For a description of the island and its remains of antiquity, see A. Conze, *Reise auf den Inseln des thrakischen Meeres*, Hanover, 1860.

THAYETMYO, a district in the Irrawaddy division of Burmah, having an area of 2397 square miles, and lying between 18° 50′ and 19° 30′ N. lat. and between 94° 30′ and 95° 50′ E. long. It is bounded on the N. by the newly acquired territory of Burmah, on the E. by Toungú district, on the S. by Prome, and on the W. by Sandoway. On the west is the Arakan Yoma range, and on the east the Pegu Yoma; and the face of the country, where it does not rise into mountains, is everywhere broken by low ranges of hills, many of which are barren and destitute of all vegetation. The greater part of the district is wooded, and the Yomas east and west are covered with forests now mostly preserved. The chief river is the Irrawaddy, which traverses Thayetmyo from north to south. The country is well drained; the drainage finds its way to the Irrawaddy by three main streams (the Pwon, Ma-htún, and Ma-de) on the west, and by two (the Kye-nee and Bhwotlay) on the east. Several salt and hot springs occur in many localities of the district; petroleum is also found, and extensive lime quarries exist a few miles south of Thayetmyo. The principal wild animals are leopards, wild cats, barking deer, elephants, rhinoceroses, tigers, black bears, and wild hogs. Silver pheasants and partridges are found in large numbers, especially in the mountains.

In 1881 the number of inhabitants in the district was 169,560 (males 87,308, females, 82,252); Hindus numbered 2620, Mohammedans, 1861, Christians, 2349, and Buddhists 148,629. The chief town is Thayetmyo, with a population (1881) of 16,097; it is situated in 19° 18′ 43″ N. lat. and 95° 15′ 40″ E. long., on the right bank of the Irrawaddy. Of the total area of 1,534,080 acres, only 108,167 were under cultivation in 1885–86; 547,631 were available for cultivation; and forests occupied 256,256 acres. The chief products are rice, cotton, oil seeds, and tobacco; cutch is also very abundant, and the manufacture of the dye-stuff is carried on extensively. Coal has recently been found in the district, and earth oil-wells exist, but neither coal nor oil has yet been extracted in any quantity. The revenue of the district in 1885-86 was returned at £36,702 [$178,371.72], of which the land contributed £10,482 [$50,942.52]. On the annexation of Pegu by the British in 1852-53, Thayetmyo was formed into a subdivision of Prome district; and in 1870 it was erected into a separate jurisdiction and placed under a deputy-commissioner.

THEATRE (*θέατρον*, "a place for seeing," from *θεάομαι*). The invention of a building specially devised for dramatic representations was due to the Athenians (see DRAMA). At first representations at the Dionysiac festivals were held on temporary wooden platforms; an accident, however, which occurred in 500 B.C. induced the Athenians to begin the construction of a permanent building. The first theatre was not completed till 340 B.C., and during the interval a large number of theatres, designed on the same model, had been erected in many towns of Greece and Asia Minor, though in some cases, as at Sparta, they were used for assemblies of the people and dances rather than for dramatic performances. The great Dionysiac theatre at Athens was placed in the Lenæum, an enclosure sacred to Dionysus, and its auditorium is scooped out of the rock at the base of the Acropolis on its southeast side. A similar position on the slope of a hill was always chosen by the Greeks, and it was not till the 1st century B.C. that theatres were built by the Romans on a level site.

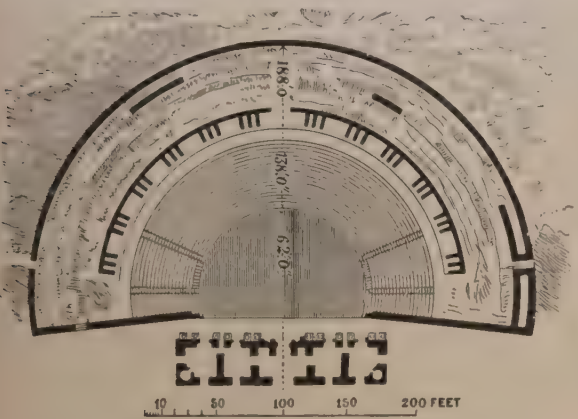

FIG. 1.—Plan of the theatre at Myra.

Fig. 1 shows the plan of the existing theatre at Myra, in the southeast of Lycia, which, though late in date, is built after the old Greek model.[1] The seats for the audience are arranged in concentric tiers, rising like steps one above the other (see Fig. 2);

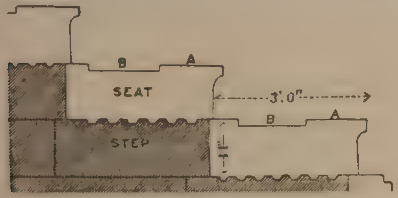

FIG. 2.—Section showing the seats A,—with B, place for spectators' feet.

these mainly rest on a cavity excavated in the hillside, and the whole space occupied by the spectators was called the *κοῖλον* (Lat. *cavea*). About half-way up the slope is an encircling passage (*διάζωμα*, *præcinctio*). Flights of steps divide the seats into wedge-shaped blocks (*κερκίδες*, *cunei*). At the highest level behind the top row of seats ran a colonnade, forming a covered passage with a gallery at the top. Rows of niches were formed in the back wall of this, and also sometimes in the low wall encircling the *διάζωμα*; in these niches a series of large bronze jars (*ἠχεῖα*) were set; they were intended to catch and repeat the reverberation of the voices from the stage. Vitruvius (iii. 5) gives elaborate directions for the construction of these vases, which were to be tuned in a chromatic scale;[2] he mentions their use by the Greeks, but says he knows of no Roman theatre which possessed these vases, the real utility of which is very problematical.[3] The segmental floor space in a Greek theatre was called the *ὀρχήστρα* (*orchestra*), and was occupied by the chorus; in the centre of this was the *θυμέλη*, a platform slightly raised on steps, in the middle of which was an altar to Dionysus. The stage (*προσκήνιον*, *proscenium*) was a narrow platform, raised 3 to 5 feet above the orchestra, with which it communicated by stairs, so that the chorus could move from one place to the other; the central part of the stage, where the principal actors usually stood, was the *λογεῖον* (*pulpitum*). The stage was also connected with a chamber under it (*ὑποσκήνιον*) by a flight of stairs called *χαρώνιοι κλίμακες*, by which ghosts ascended. At the back of the stage was a lofty wall, which usually reached to the level of the colonnade behind the highest row of seats; this was the *σκηνή* (*scena*), in which were three doors leading into the stage from the actors' dressing-rooms behind it.[4] This wall was usually decorated with three orders of columns and entablatures, forming an architectural façade, which represented a palace or temple, before which the action of the play was supposed to take place. Other movable wooden scenery was in some cases added in front of the permanent scena; or curtains with woven or embroidered figures were hung against it to form a background to the actors (*παραπέτασμα* or *αὐλαίαι*, *aulæa* or *siparium*). More elaborate painted scenes were also used, but, according to Aristotle (*Poet.*, iv. 16), not before the time of Sophocles. Various kinds of machinery were used, such as the *μηχανή*, to suspend in the air an actor who was playing the part of a god descending from heaven;[5] and the *βροντεῖον*, an apparatus to imitate thunder by stones rolled in metal jars, probably in the ghost-chamber under the stage. Women were not excluded from the Greek tragic drama, but appear to have sat by themselves in the upper rows of seats (Athenæus, xii. 534).[6] At least in late times the chief priestesses of Athens occupied marble thrones in the *προεδρία* or front row.
